6 lines . ... £ 0 5 0

And 9*d*. per line for every additional line—Average 11 words to a line.

TO INVESTORS.

AN excellent opportunity occurs for securing a Half Share in a well-established Tea Estate, situated in a most healthy part of the Neilgherries, and only 30 hours by cart and rail from the nearest sea-port Labour and Fuel are both abundant in the neighbourhood.

The Estate which is upwards of one hundred acres in extent, comprises a large well built house with stables and offices complete, factories, &c., with machinery worked by water power. About seventy two per cent of the acreage is under tea, more than half of which is in full bearing There are besides about twenty thousand Gum and some Cinchona trees on the plantation. Price of Half Share, £2,750 Sterling.

N B.—The refusal of the other half share could probably be arranged or if desired.

For further particulars, apply to Nicholls & Co, 8, Old Court House-street, Calcutta, or 1, Whitefriar's-street, Fleet-street, London, E C.

FLAX.

A GENTLEMAN experienced in the cultivation and preparation of flax, is open to an engagement during the ensuing season.

The following are some of the advantages of W. & A. Gilbey's system of business :—

VALUE.—The extent of W. & A. Gilbey's purchases enables them to give the best value to the public. The duty payments shew that a twentieth part of the Foreign Wines consumed in the United Kingdom is supplied from their Stock.

QUALITY.—Quality is guaranted by W. & A. Gilbey, and is the same whether the Wines and Spirits are obtained direct from their head Establishment or from any of their Agents. The purity and genuineness of all the above Wines are guaranteed in accordance with Act of Parliament 38 and 39 Vic. Capt. 63.

MEASURE.—W. & A. Gilbey have always adhered to the standard of bottle measure recently recognised by Government, *viz.*—

6 bottles contain One Gallon ; 12 half bottles contain One Gallon.

TERMS.—Cash to new Constituents ; 30 days to known and approved Constituents. Every article not approved of received back after 24 hours,

MISCELLANEOUS.

THE

CALCUTTA MUSICAL ESTABLISHMENT,

No. 13/1, Government-place, East.

(LATE BURKINYOUNG & CO.)

FOUNDED, A.D. 1814.

PROPRIETOR—CHARLES GOULD.

THE SMITH AMERICAN ORGAN,

Wholly new designs and effective combinations in Reed Organs.

THE American Organ has been, and still is, the most popular and valued instrument for Churches and Chapels. Immense numbers of them are used in public worship, and it has been found that no other Reed Organs have so much sustaining power joined with such melodious quality of tone.

Style No. 10, *Seven Stops.*

This Style is furnished with two complete sets of reeds of five Octaves. Each set is divided and has a separate stop, for the upper and lower half. The upper half of the first set of reeds is named Flute, and the lower half Principal. In the second set the upper half is named Dulciana, and the lower Diapason. The first set is an Octave higher in pitch than the second, so that the instrument has practically a compass of six Octaves. By having the sets divided, it will be seen that more effect can be produced. The remaining stops are Tremelo, Diapason Forte, and Principal Forte. [*Net Cash, Rs.* 400.

Style No. 16, *Ten Stops.*

This instrument has two-and-a-half sets of reeds, and an Octave of Sub-bass. It has ten stops, *viz.*, Diapason, Dulciana, Flute, Principal Kulophon, Sub-bass, Tremelo, Principal Forte, Diapason Forte, and Octave Coupler. The last stop doubles the power of the Organ, and with the aid of the Sub-bass renders it a powerful and effective instrument for Churches and Halls ; at the same time its power is not obtained at any sacrifice of delicacy, and it will be found a most desirable instrument for home use. [*Net Cash, Rs.* 550.

Style No. 20, *Nine Stops.*

This instrument has three complete sets of reeds. Two of the sets are like those in the preceding Styles, having the Principal and Forte Diapason and Dulciana stops. The third set is new and distinct in quality, the upper half is named "Aulodia" and the lower half "Fagotte." The tones of this set are unrivalled in clearness, smoothness, and tender beauty, and their effects in connection with the swell are surprising.

This Organ is one that will be approved by all persons of refined taste. [*Net Cash, Rs.* 750.

N.B.—The above prices are exclusive of packing charges.

THE BENGAL PURVEYING CO.,

GENERAL DEALERS AND COMMISSION AGENTS,
61-3, Municipal Market.

VEGETABLE ASH MANURE,

RECOMMENDED FOR

TEA, COFFEE, AND INDIGO,

Manufactured from the Ashes of Cow-dung, Horse-dung, &c., supplemented by Bone-dust and Potash Salt.
It is essentially a nourishing, not a forcing Manure.

The manure has been greatly improved by the successful separation of most of the useless matter and, as now manufactured contains :—

30 per cent. of soluble Alkalies (Chloride of Potassium and Sodium, and Sulphate of Potash).
20 „ Lime and Magnesia.
7 „ Phosphoric Acid, equal to 15 per cent. of Phosphate of Lime.

The remainder being Sulphuric Acid, Iron, Carbonic Acid, organic nitrogenous matter and Silica.

The manufacturers are indebted to Messrs. Gillanders, Arbuthnot & Co. for the following Extract from the Fortnightly Report of the Manager "Burkhola Tea Estate," dated 2nd October 1878.

MANURE EXPERIMENTS.

TWO PLOTS, OF 2,793 TEA BUSHES, EACH YIELDED LEAF.

	Vegetable Ash Manure.	*No Manure.*
"*Up to date of last Report*	1,414lb.	1,096lb.
"*During the fortnight under Report*	260lb.	195lb.
"*Total up to date* ...	1,674lb.	1,291lb."

That is 30 per cent. increase in favour of the manured portion.

The manure was applied in March last, at the rate of 10 cwts. per acre, and can scarcely be said to have exerted its full influence as yet.

The Manager, "Mulla Kuttyoor Tea Concern" writes, under date September 19th, 1878, to Messrs. Begg, Dunlop & Co :—

"*The Vegetable Ash Manure I got up from you as a sample, I have tried on some sickly bushes, and its effect has certainly been beneficial.*"

Sold in strong bags, ready for shipment, at Rs. 50 per ton, inclusive of bags.

A still further concentrated manure, containing 40 *per cent. of soluble Alkalies* and, additionally, 2 to 2½ per cent. of Nitrogen, specially suited for Coffee, at Rs. 65 per ton.

Delivery at the Godowns of the undersigned.

PUBLISHED IN LONDON.

THE STATESMAN.

A new weekly paper devoted to the discussion of political questions, and especially to a consideration of the economic and administrative reforms called for by the present condition of India, and our relations with that Empire. The Journal is a high class periodical, published in London, in close correspondence with the* STATESMAN AND FRIEND OF INDIA *in Calcutta.

THERE are many cogent reasons why such a paper, as we propose to establish, should receive the support of our countrymen at home. When the Government of India was transferred from the Court of Directors to the Crown, it was inevitable that, sooner or later, the initiative in policy and legislation should also be changed from Calcutta to London. The effects of this transfer are, that the authorities in India are relieved from responsibility to even such feeble public opinion as there exists, while from the ignorance and indifference at Home, the Indian Government in London becomes more despotic than ever. A Government which rules India from Calcutta cannot entirely close its eyes and ears to the effect of its measures upon the people; but an irresponsible Bureaucracy attempting to govern India from Downing-street, legislates in the dark. It can know nothing of the wants of the people, except what is to be gathered from official reports, prepared so as to suit its wishes. The only way to correct this evil, is to raise up in England an enlightened interest in India, by making known, from free and unbiassed sources of information, the veritable state of the country and the character of the administration. In order to do this effectually, it is essential that the London journal should have its roots, so to speak in India. For Western ideas are a solvent of tremendous power; and under their influence, India is changing with a rapidity which must be watched to be understood. It results from this, that an English journal desiring to disseminate the truth regarding India, must obtain its information fresh and fresh, from writers in immediate contact with the facts, convictions, wishes, and aspirations which they delineate. By the establishment of London *Statesman*, in direct connection with a *Statesman* in Calcutta, this object would be accomplished.

Again, all history bears testimony to the fact, that a Government not exposed to the bracing atmosphere of free criticism, becomes corrupt and inefficient. Among Englishmen at least, this may be assumed as a political axiom. We should all of us feel, that if personal rule were set up in England, the national greatness and prosperity would swiftly wither and be lost. And yet, by a curious inconsistency, it is by means of personal irresponsible rule, that we have thought to secure the prosperity of India, and the happiness of its people. This political miracle has not come to pass. Englishmen entrusted with despotic power have too often succumbed to its corrupting influences. They have learned to believe that in *their* case might was right, that because they were entrusted with a mission to elevate and improve the people of India, they might, in their dealings with that people, dispense with those moral laws without which no elevation of character is possible. Everything was to be done *for* the people; nothing was to be done *by* the people. And the consequence has been, that the people of India have been treated by us as a *corpus vile*, on which administrative theorists and crotchet-mongers had full power to experiment as they pleased. There has been neither continuity of principle, nor consistent purpose in our administration, but a series of vast experiments, precipitate in their inception, and disastrous in their consequences. Thus it is that at the close of a century of British rule, carried on to a ceaseless chorus of self-congratulation, we find these singular effects:—A profound gulf existing between rulers and ruled; a peasantry sunk in poverty and indebtedness, and swept away in millions by periodical famines; an army, the most costly in the world, and yet so deficient in organisation that we cannot, in three months, collect 30,000 men on our own frontier; a heavy public debt, an increasing expenditure, and the Empire on the very verge of bankruptcy. We do not say that this comprises the whole of the picture, or that there are not brighter scenes to be found in it. But this we do say, that the above facts are strictly true, and the demand that we should cease from contemplating Narcissus-like, our own perfections, and try to ascertain how and why we have so grievously failed. But this again is impossible, unless a clearer and more accurate knowledge of India is generated in England than at present prevails there.

Lastly, each succeeding year exhibits more clearly that the entire Foreign policy of Great Britain revolves round our Indian Empire. Peace or war in the mother country depends upon the opinions formed by the Government of the day, as to the degree of peril which menaces India from this or that Power. At this very time we are engaged in a war, the injustice and cowardice of which are patent, because Lord Beaconsfield and his colleagues think that something must be done to check the progress of Russia in Central Asia. Urged onward by this vague desire to do something, they estrange the Amir Shere Ali by persistently menacing his independence; and then make that estrangement the justification for carrying their menaces into execution. Even assuming that Englishmen were willing to overlook the profligacy of such a policy, they cannot afford to treat it with indifference. For it is certain that the costs of an occupation of Afghanistan will have to be defrayed by them. The "scientific frontier" is a meaningless absurdity. If we annex any portion of Afghanistan, we shall be compelled, at no distant date, to annex the whole. It is absolutely certain that India will not be able to furnish the funds for such an acquisition; and the burden must therefore fall upon Great Britain. Are the British tax-payers willing to pay ten millions a year for the doubtful advantage of a "scientific frontier?" Eighteen months ago the Calcutta *Statesman* detected the designs of Lord Beaconsfield's Government, and warned its readers of what was coming. But in Indian official circles its warnings were unheeded, and in England unheard. Had there been in London such an organ of information regarding India, it is well-nigh certain that the present war would have been averted. For at every step the misrepresentations of Government would have been brushed aside, and their veritable policy laid bare; a healthy and enlightened public opinion would have had time to form; and Lord Beaconsfield's policy of "surprising" the country into a war would have been rendered impossible.

But though India will be our speciality, the paper we establish will not be exclusively Indian, but will deal with the whole range of English Politics, domestic as well as foreign, insular as well as Imperial. Social questions and current literature will also receive their due share of regard therein. What we aim at is a high class Liberal paper, interested in all matters in which the nation at large is interested, discussing them in the light of advanced Liberal principles, and accepting of the expression of our policy, the old Liberal sentiment—"The cause of Civil and Religious Liberty all over the world."

The idea is to establish a weekly organ of advanced Liberalism conducted by earnest Christian gentlemen whose interest in Indian affairs is paramount by the circumstance of their connection with the country, and exact knowledge of its affairs and administration. It will contain a weekly summary of the latest news from all the Indian papers, brought down to date by the latest telegraphic advices, and reviewed in their light. There is no such paper now, and the conception is believed to be a sound one. Our hope is to awaken by means of the paper, a deeper interest in India, and a higher sense of our responsibilities as its rulers, than unhappily at present exists; and to do this by floating Indian affairs into public notice, on the strength of the Imperial and domestic interests which they so vitally affect.

JEBENS' PATENT

Swift and Sure Transplanting Tools.

PROSPECTUSES NOW READY AND MAY BE HAD ON APPLICATION TO THE MANUFACTURERS.

T. E. THOMSON & CO.,

9, ESPLANADE-ROW, CALCUTTA.

SOME of the advantages of these tools are the security that, with very ordinary care, no injury can be done to plants and roots, and the swiftness, simplicity, and cheapness of working. The growth of the plant is not at all arrested in transplanting; it grows as if it had not been shifted. Transplanting can be done at all times with little regard to weather. No vacancies or weakly trees from injured roots. The greatest care has been taken to strengthen all working parts. Specially devised to be put into the hands of the coolie.

Mr. J. W. Mountjoy of Pandawbrang, Arracan, writes as follows regarding these tools :—

"The Transplanter has in working proved to be a complete success. Almost all the remaining seedlings have been transplanted by the aid of your instrument, without the slightest injury to their roots or check to their growth. The fact is, the young plants do not know that they have been transplanted, and now that sunshine has succeeded the late very heavy rains, new and vigorous growth is "bursting out" from all the seedlings that were transplanted by means of your Transplanter. No Manager of a Tea or Coffee plantation, who had once seen this instrument at work, would ever again be likely to recur to transplanting by hand, and not a single seedling should die when removed from the nursery and carried to its place of ultimate growth by means of your Transporter. Your Transplanting Apparatus is better than baskets, and has moreover the great recommendation of being very economical. Your Transplanter will, with moderate care, last for many years, and combines thorough economy with thorough efficiency."

ORDERS are now being booked and will be executed in succession as received by the Manufacturers and Agents to the Patentee, T. E. THOMSON & CO., 9, ESPLANADE-ROW, CALCUTTA, to whom orders should be sent accompanied by CASH or Draft on Calcutta Agent.

Domestic ditto ditto with and without weights.
Salter's Spring Balances.

A large Stock always on hand of Best Sheffield Files and Patent Woodscrews, Locks, Bolts, Hinges, Nails, Chain, Iron, Steel, Brass, Copper, Zinc, Tin, Lead, Oil, Paints, Varnishes, and Turpentine.

Prices and particulars on application.

PHŒNIX IRON WORKS,

CALCUTTA.

THE OLDEST ENGINEERING ESTABLISHMENT IN INDIA.

JESSOP & CO.,

Civil and Mechanical Engineers, Contractors, Brass and Iron Founders, Metal Merchants, &c.

Forged and Cast Iron Work, Boilers, Machinery for Jute, Cotton, and Rice Mills, Collieries, Indigo Concerns, Tea Gardens, &c., Contractors and Brick-making Plant, and every class of Iron and Brass Work made to order.

SOLE AGENTS FOR

Robey & Co.'s celebrated Portable and Fixed Engines and Machinery, Gwynne & Co.'s Centrifugal Pumps, Gould's Rotary Pumps, and Robinson's Patent Steam Traps.

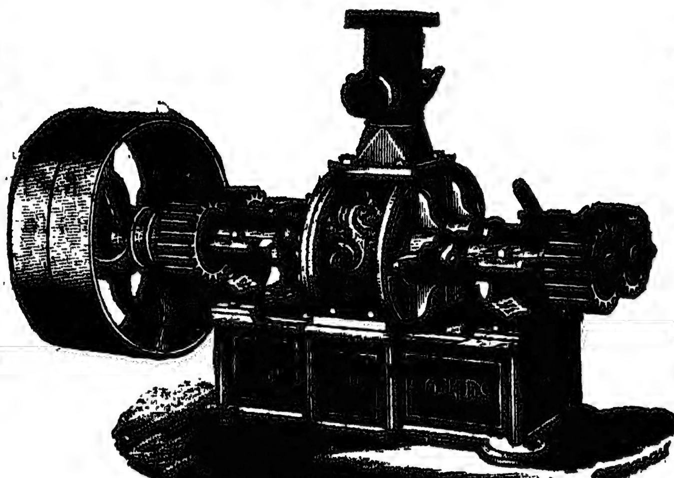
Importers and Manufacturers of every description of Steam Engines and Machinery.

Robey & Co.'s Portable, Horizontal Fixed, and Patent "Robey" Semi-fixed Engines, Combined Vertical Engines and Boilers, Land and Marine Boilers, Gould's Rotary Power Pumps, Hand Lift and Force Pumps, Gwynne's Centrifugal Pumps, Tangye's "Special" Steam Pump, "Vauxhall" Donkey Pumps, Flour Mills, Soorkee Mills, Pug Mills, Brick-making Machines, Road Rollers, Saw Benches, Stoney's Patent Soorkee Screwing Machines and Double Acting Helical Excavators, Slide Surfacing and Screw Cutting Lathes, Drilling Machines, Punching and Shearing, Slotting and Screwing Machines, Emery Grinding Machines, Spencer's Hand Drilling Machines, Chaff Cutting Machines, Kennedy's Patent Bar Shears, Selkirk's Boiler Tube Beaders, Steam Pressure Recorders, Electric Pens, Richard's Engine Indicators, Gifford's Injectors, Cooking Stoves, Fire Proof Safes.

No. 3 Pump, has a 3 inch suction pipe, throws a 2½-inch stream, and with 175 revolutions discharges 175 gallons per minute.

No. 4 Pump, has a 5-inch suction pipe, throws a 4-inch stream, and with 200 revolutions discharges 325 gallons per minute.

No. 5 Pump, has a 6-inch suction pipe, throws a 5-inch stream, and with 200 revolutions discharges 560 gallons per minute.



The mandrels of these Pumps are made of cast-steel with Babbet's metal boxes, and there are no valves or leather packing, which renders them very durable and not likely to get out of order. The great advantage of these over the ordinary Centrifugal Pumps is that they will draw water running at any rate of speed, but of course the higher the speed a which they are driven the greater the discharge obtained.

GOULD'S ROTARY PUMP.

INDIGO AND TEA PLANTERS' IMPLEMENTS AND STORES.

Indigo Screws, Indigo Beaters, Indigo Pans, Indigo Pumps, Howard's Patent D and Turnwrest Ploughs, Kodallies, Pruning and Budding Knives, Grubbing Hoes, Assam Daws and Forks, Bill Hooks, American Felling Axes, Scissors, Shears, Saws, Mowing Machines, Tea Sieves, Tea Lead Solder, Galvanized Netting, Iron and Brass Wire Gauze, Leather and India-rubber Belting, Tool Chests, Grindstones, India-rubber Suction and Delivery Hose, Canvas Hose, French Wire and other Nails, Hoop Iron, Platform Weighing Machines, Spring Balances, Gram and Oat Crushing Machines, Maximum and Minimum Thermometers, Steel Band Chains for land measuring.

ENGINEERS' TOOLS AND STORES OF ALL KINDS.

Duplex Punches, Boiler Bears, Lifting Jacks, Stocks and Dies, Ratchet Braces, Tube Expanders and Cutters, Engine, Spindle, and Small Machine Counters, Vacuum and Pressure Gauges, Hydraulic Gauges, Boiler Tubes, Steam and Hydraulic Piping, Boiler Cocks and Fittings, Triple Acting Ratchet Braces, Horse Power Computing Scales, Angular Bit Stocks, Stephen's American Parallel Vices, Adjustable Clamps, Adjustable Iron Block Planes, Cranes, Vegetable Oil, "Climax" Pipe Wrenches, Box Scrapers, Patent Glass Cutters, Boiler Rivets, Bolts and Nuts, Coach and Wood Screws, &c., &c.

McRAE'S PATENT SUB-SOIL AND GENERAL PLOUGH.

This plough, of which we have been appointed sole manufacturers by the Patentee, is comparatively light and cheap, and stirs up the soil to three times the depth of a native Plough, and for a breadth of at least seven inches, leaving the good mould on the top. Particulars and prices on application.

Always on hand a large stock of Plate, Bar, Angle, Tee and Corrugated Iron, Steel, Brass, Copper, Pig Iron, Foundry Coke, Smithy Coal, Fire Bricks, and Fire Clay.

Catalogues on Application.

HYDRAULIC AND SCREW PRESSES, OIL MILL MACHINERY, HYDRAULIC LIFTS, &c.

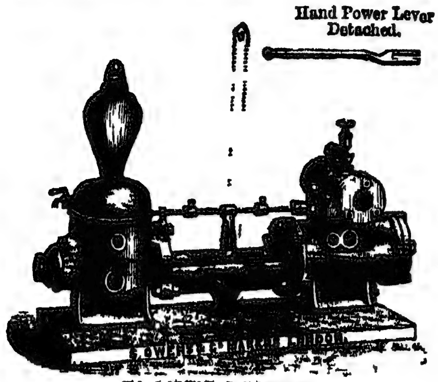
SOLE MAKERS FOR GREAT BRITAIN OF

BLAKE'S PATENT DIRECT-ACTING STEAM-PUMP, MORE THAN 10,000 IN USE.

The following are some of the promnent advantages of the Blake Pump :—

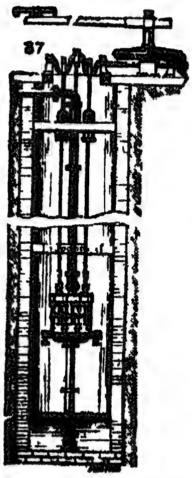
It will start at any point of stroke.
It has no dead point.
It works fast or slow with the same certainty of action.
It is economical. Has a lead on the Slide Valve.
It is compact and durable.

Hand Power Lever Detached.

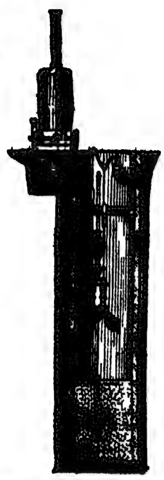


BLAKE'S PATENT
Direct-Acting Steam Pump and Boiler Feeder

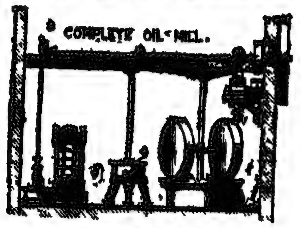
It is interchangeable in all its working parts.
It will deliver more water than any other Pump.
It is made of best materials in the most workmanlike manner.
Can be worked at 200 strokes per hour, or 20 strokes per minute.



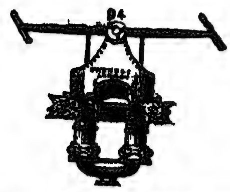
Deep-well Pumps, for Horse or Bullock power.



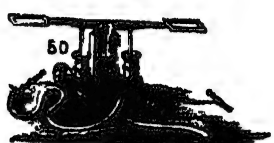
Vertical Combined Steam Engine, Boiler, and Deep-well Pumps.



Oil Mills, for Steam or Cattle Power

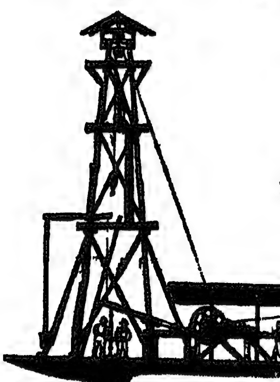


Double barrel Contractors' Pumps, for hand or steam power.

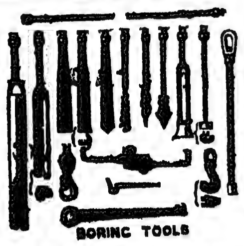


Double-barrel Fire Engine, for Mansions, Factories, &c.

Deep-well Pump or Hand Power

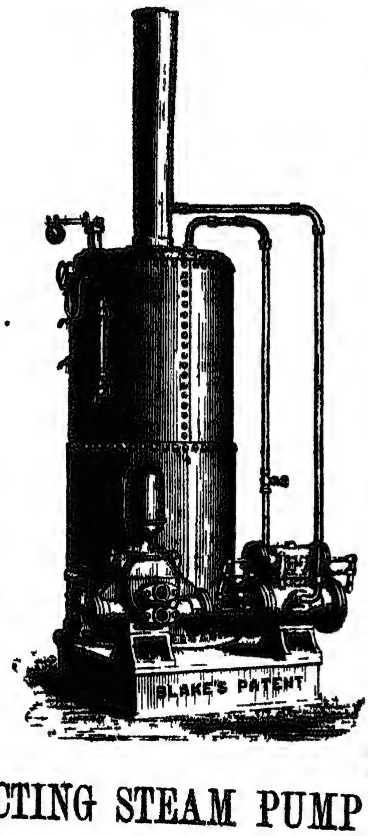


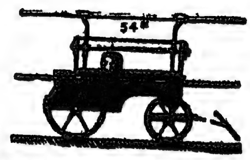
Improved Steam Boring Apparatus, also



Boring Tools of every description, for Artesian Wells, testing for Minerals, Foundations, &c

Double barrel Force Pumps in Frame.

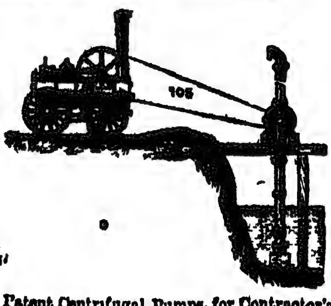




Fire Engines, for Towns, Railway Stations, &c.

Force Pumps on Barrow.

Wrought Iron Portable Pumps.



Patent Centrifugal Pumps, for Contractor's use, or Irrigation work.

Cast Iron House or Garden Pump

Portable Irrigators for Horse or Steam Power.

BLAKE'S PATENT DIRECT-ACTING STEAM PUMP AND VERTICAL BOILER

FOR IRRIGATION PURPOSES,

FILLING TANKS, WATER-SUPPLY TO PLANTATIONS, SMALL TOWNS OR VILLAGES.

WHITEFRIAR'S IRONWORKS, WHITEFRIAR'S-ST., FLEET-STREET, LONDON.

BIRD & CO.,

MANUFACTURERS OF THE

PATENT IMPROVED LEATHER—

OIL-PROOF, WATER-PROOF, IMPERISHABLE.

WORKS:—

LIME-HOUSE, LONDON, E.

THIS Leather is submitted to a patent process, rendering it stronger, more durable, and impervious to damp and heat. Being water-proof, it is particularly adapted to work in wet and exposed situations, and in the hot and moist atmosphere of the Tropics.

THE BANDS

Will stretch less than those made of ordinary leather, thus saving both the time and trouble so frequently expended in taking up belting; while for agricultural purposes, where the Bands have to remain in the open, this Leather will be found invaluable.

THE HOSE PIPING.

Besides being stronger than ordinary hose, never becomes hard, requires no oiling or dressing, and after being used, can be put away until next wanted without any further care or labour being bestowed upon it.

THE BUCKETS

Are handsomer, stronger, and lighter, and will last longer than those made of wood or iron.

THE HARNESS

Will bear exposure to the heaviest rain, only requires to be wiped with a dry cloth; neither oiling nor dressing is wanted. The leather, which is particularly recommended for Cart and Heavy Harness, though equally valuable for lighter purposes, such as Carriage Hoods, Aprons, &c.

BOOT AND SHOE PURPOSES.

The Soles and Clumps are perfectly impervious to rain and snow water, and keep the feet warm and dry in the coldest or wettest weather. Uppers can also be made waterproof.

ARMY PURPOSES.

This Patent Leather will be found most valuable and economical in the various departments of the Army, retaining its specific properties until worn out, and requiring but little care and attention; the saving in time and money, in Artillery harness alone will be great. This Leather will be found particularly adapted for use in India and all tropical climates, where the great heat and moisture prove so destructive to ordinary Leather.

GENERAL PURPOSES.

There are of course numberless other purposes to which this Leather can be applied, at, *viz*:—Pump Leathers, Portmanteaus, Bags, Gun Cases, Cartridge Boxes, Belts, Straps, &c., &c., and any information required can be obtained on application at the Works, Limehouse, London, E.

Proprietor.

Calcutta, 1st Feb. 1876.

CONTENTS:

NOTICE TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

THE CROTON-OIL TREE.

TO THE EDITOR.

SIR,—With reference to the notice of the Croton-oil tree in your issue of the 1st ultimo, I beg to ask if you could tell me the *Hindustani* name of the tree, and whether you think it would suit the climate of the North-West? We have plenty of bare spaces in the Doon that would be all the better for tree shade; and the quicker growing the tree, the better.

F.

Dehra Doon, 20th December 1880.

P.S.—Is the name *Jumal Gotee*; and where can the seed be procured?

NOTE.—Yes, the Hindustani name is Jumal Gotee, and it grows wild in great profusion along the foot of the hills near Jumalpore, which station, it is supposed, derives its name from the presence of the plant.—ED. *I. A.*

TEA.

TO THE EDITOR.

SIR,—It is a matter of no small importance, to those concerned, to find their fine classes of tea selling at only one anna or perhaps two above the inferior kinds. If those interested do not demand an explanation, it is their own fault, and I believe any one of experience will agree that when such a state of affairs exists, there is something *radically* wrong in the system of manufacture. Making all allowance for the market, it is ridiculous to hear the prices some gardens' Pekoes and Broken Pekoes sell at in the open market, as compared with common broken Souchong. Let us hope the idea, started some months ago, is not gaining ground—that good and inferior qualities fetch about the same price. There is little doubt that planters have expressed this opinion. Can it be that they have relaxed their tea-house supervision on this account? This is a matter for those interested to inquire into.

OUTSIDER.

CORUNDUM.

TO THE EDITOR.

SIR,—I am anxious to find out a few facts about the mineral Corundum, which is now being mined over a large portion of some of the talugs in the district:

First, what is its chief use?

Secondly, what is the price it fetches in the market at home?

Thirdly, where is it chiefly mined now?

The mineral is dug up by the landholders here and sold by the seer measure to native merchants who take it away to Madras and Bombay.

I suspect that the ryots at present sell it much under the price which it would fetch were they able to take advantage of the demand.

RAILWAY SLEEPERS.

TO THE EDITOR.

SIR,—In your issue for the 1st November last, No. 11, page 296, there was a very interesting suggestion for seasoning the *deodar* timber. Within the past few days there has occurred good opportunity of verifying—in part—the usefulness of that idea. To wit:—

At the Government Timber Dépôt at Wazirbhullar—adjacent to the Beas station S P D.R—there are nearly twenty thousand sleepers brought down from the Himalayan forests bordering the upper portion of the river Beas, and now being taken over for the P.N.(S.)R.

The trees, whence these sleepers were cut, were felled, cleared of branches, and logged, in the usual way. But instead of the sleepers having been at once thrown into the river to be despatched to the plains *they were allowed to remain in their Himalayan homes for two years, for the purpose of seasoning.* The result is satisfactory, and would have been much more so had the trees been girdled, or

felled, and allowed to remain intact for two years before they were converted into sleepers.

The chief defect in the sleepers, now at the Wazirbhullar depôt, is owing to the longitudinal split in those cut from the centre of the tree, due to the too hasty conversion of the tree into sleepers; this split would not have happened had the trees been girdled for a couple of years, before being felled. The wood is knotty, but, in seasoned timber, this is not of much importance, as the knot does not easily separate from the wood, which only happens in unseasoned timber where, under the rays of the tropical sun, the two are torn asunder, and so the timber is rendered useless. At the Wazirbhullar depôt the greater portion of the sleepers are stacked under thatched coverings, thus preserving them still more; this is very apparent by an examination of the ends of the sleepers stacked outside and those under cover, the former showing splits, from the heat of the sun, from nine inches to a foot in length, thus detracting from the value and usefulness of the sleeper.

There is no doubt that the Punjab Forest Department could supply a lakh of first class broad gauge sleepers every year to the railway companies; and if only the same care be taken on the other rivers, as on the Beas, in sawing, launching, rafting, and storing sleepers (great credit is due to all concerned in these operations) the rejections need never exceed five per cent, even if so much, and even these could be disposed of, for door and window frames &c, &c. In this way the Government would save paying away three-and-a-half lakhs of rupees annually to *baparies* for an inferior article which may only last, at the outside, eight to ten years, whereas these Beas sleepers will last twelve to fifteen years; and sleepers which have been cut from trees, girdled for two years before being converted into sleepers, would last fifteen to twenty. At all events with this example of the Beas sleepers before Government it behoves it to try the experiment with five hundred trees on each of the Himalayan rivers. In 1865, or thereabouts an experiment in connection with sawing up sleepers, was tried on the Ravi river, and a large number were rejected chiefly on account of splits, occasioned by the cutting up of unseasoned wood into sleepers: these rejections gave the experiment a bad name, and the Government appear to have sat down quietly for years, under the supposition that the supplying of sleepers to the railways would not pay: the cause never appears to have been inquired into, nor any remedy proposed.

Some of the best and most seasoned timber ever brought down from the Himalayan forests belonged to the old English firm, Messrs. Brassy Wythes, and Henfrey: a large portion was felled in 1866-68. and not launched until 1868-71; the consequence was the timber was perfect, and there was no such thing as a longitudinal split in the centre of the logs. After this, need more be said about the advisability of allowing the tree to season before being converted into sleepers, or into log? The trees were cut in the summer months.

ANOTHER FORESTER.

"WHEAT RICE."

TO THE EDITOR.

SIR,—In your issue for December, (received yesterday), your Mysore correspondent, "C.G.S," asks you to put him in the way of obtaining some seed of the *Sorghum Saccharatum*, or Chinese Sugar-cane, which he has been led to believe is identical with the new cereal called "Wheat rice," which has not as yet reached India. If your correspondent will send me his name and address in full, I will with pleasure give him half-a-pound of *S. saccharatum* seed, with instructions as to its culture.

I hope to receive a supply of the new cereal (Wheat rice) and may be able to spare some of it for your correspondent to try.

FRED. POGSON.

Millward Cottage, Kotegurh, 7th Dec. 1880.

ABOUT PAPER FIBRES.

TO THE EDITOR.

SIR,—I have just received the October number of your journal, and note the editorial reference therein to the report of the Royal Botanical Garden, Calcutta, 1879-80, which I dare say I shall shortly obtain and be able to study *in extenso*; meanwhile I beg to make a few comments on your article in continuation of my last letter referring to Mr. Liotard's memorandum.

Fully agreeing with you Sir, "*that the demand for paper is steadily increasing in a much faster ratio than is the supply of paper stock,*" endorsed by the late considerable rise in the price of *Esparto* grass, our present chief paper-making material, I must take exception to your remarks that "astonishing improvements in *machinery* have equalised the increase in the price of rags and grasses used for paper-making;" the fact being that the use of grasses, and I am only aware of one grass, and that *Esparto*, being hitherto used, at least in this country, has involved no improvement *in machinery*, the same machinery being employed for it as heretofore for rags, the only difference in the treatment between rags and grasses (generally so called) being the *chemical* treatment.

Now this chemical treatment consists in boiling the grass, or grasses, in alkaline leys to dissolve and discharge the glutinous, gummo-resinous, and coloring matters other than the fibrous residue, which latter has then to be purified by washing, to fit it for the subsequent bleaching process, and I am afraid that very few of the Indian grasses, (this somewhat costly process incurred, considering their yield of pure fibre, and adding thereto the cost of collection, inland transport, and freight to Europe,) can successfully compete with *Esparto* grass, either in respect to the quality of the stock producible therefrom, or the price at which the same can be laid down in this market *to pay a profit.*

Experimenting on the yield (to say nothing of the quality) of fibres, especially grasses, and their adaptability for paper-making requires considerable technical knowledge, failing which the results recorded are likely to prove fallacious, for instance in your notice of the Botanical Garden Report, it is stated that "out of twenty-five *experiments* with *Esparto*, it was found that the highest yield was 47·2, and the lowest 39·5 per cent." *Esparto* grass varies considerably in quality, and it is not stated what description of *Esparto* was tested; whether Spanish or African Alfa, nor whether the yield was for green, or unbleached fibre, neither is any reference made to the quality of such fibre. Now for the last 25 years I have been using *Esparto* on a practical working scale, manufacturing therefrom *some thousands of tons yearly* during that period, into paper-stock, half stuff, and paper, and *never yet* found my yield of sound white paper less than 46 *per cent* with all the accruing loss of yield during the mechanical treatment of that operation added. I do not know what the botanical names of the grasses, *Ranikaria* and *Kia nsia* may be, but it is just possible that if they were experimented upon in the same way as my poor old friend *Esparto* they may have suffered in the same manner. This question of the difference *in yield*, that is the product of "stock" or fibre from the plant treated, and the cost of such treatment, is a very important factor; but that *of the quality* of the resulting fibre is still more important. For, a fibrous "stock" of superior quality being a great *desideratum*, will command a sale, whereas a "stock" barely equal to *Esparto* will with difficulty find a market.

In his Annual Report (1877-78) Dr. King refers to my report on four Indian grasses I received from the India Office for experiment; from this I quote:—

"1 *Eriophorum comosum*, "bhabar-ghas," largely used for ropes in Upper India,

"2 *Saccharum spontaneum*, known as "kash."

"3 *Imperata cylindrica*, "Ooloo" grass.

"4 *Typha elephantina*, Hogla of Bengalies.

"*Eriophorum* is the best and most easily worked of the four; the "ultimate fibre very fine and delicate, rather more so than *Esparto*, "and of about the same strength, the yield 42 per cent., somewhat less.

"*Saccharum spontaneum* ranks next, but is more tender, and "certainly not equal to *Esparto*; it yields 44 per cent. *Imperata* "*cylindrica* I do not think suitable for paper, it is full of small "joints and knots which result in harsh woody sheaves; it gives a "yield of 41 per cent. *Typha latifolia* gives a strong fibre when purged "of its glutinous compounds, but the yield is very small, only 28 per "cent.

"I do not consider that it would pay commercially to attempt to treat "any one of these fibrous materials for conversion into "stock" for "European use, although very possibly, if procurable in abundance and "at cheap rates, they might be employed for paper-making locally "with advantage."

Since the above report was written, I have tested the *Munja* or "Sur grass," *Saccharum munja*, and found it superior to any of the foregoing. The small sample which came into my hands was very bright and clean, and had evidently been very carefully selected. The yield of this in the grey, *i.e.*, unbleached, was over 50 per cent and the resulting fibre quite equal to *Esparto* in quality, if not superior; but this could only be determined by working it into paper on a practical scale.

In Mr. Liotard's Memorandum, *vide* Cap. VI. as also in Dr. Royle's book "The Fibrous Plants of India," it is stated that the four varieties of *Saccharum, viz., S. munja, S. sara, S. procerum*, and *S. spontaneum*, so nearly resemble each other in general appearance, as to be mistaken one for the other—(such is also the case with *Esparto, Machrochloa tenacissima*, and Alfa, *Stipa tenacissima*). My experiments lead me to infer that *S. munja* approaches more nearly in quality and yield of fibre to *Esparto* than any other grasses I have

yet seen, and—assuming it procurable cheaply and abundantly, if judiciously cropped, that is, selected and cut at a proper stage of growth, and carefully converted into "stock" so as to economise freight and transport—it is very probable that it would favorably compete with *Esparto* and meet with a ready sale in the English market.

I have made strong white paper from maize leaves, also from rice straw, but neither of these plants afford a yield of pure fibre exceeding 36 per cent, consequently to convert them into "stock" in India for our market would not pay.

The grass, however, of all grasses, is the gigantic grass bamboo, which I believe to be as abundant, and procurable as cheap as any of the foregoing. Its treatment is simple, and it affords a yield of pure fibre of from 60 to 65 per cent unbleached as stock. That fibre is very far superior to *Esparto*, assimilating in its characteristics to flax and hemp, thus producing the great desideratum a firm strong paper, whereas very few of the grasses I have met with as yet, (and I have tested many more than those enumerated) are equal to *Esparto*, many of them not so good.

I will resume my remarks on other Indian fibres in my next, meanwhile being desirous of assisting in the further development of the supply of paper materials, I shall be happy to test and report upon any fibres transmitted to me for that purpose, and I may add that for preliminary experiment one or two pounds per "sample post" will suffice accompanied by details as to growth, locality, &c., &c.

THOS. ROUTLEDGE.

Claxheugh, Sunderland, 8th Nov. 1880.

CROTON OIL AND SEED.

(*To the Editor of the Ceylon Observer.*)

DEAR SIR,—I thank your correspondent signed "Caution" in your issue of 20th instant. I have since written to Mr. A. Whyte of Kandy, and now send you copy of my letter and his reply ; he also informs me that he has written to you an explanation.

It is not because I have a large quantity of seed on hand for sale, but because I thought Croton is profitable, and a good shade tree. Even, taking the seed at 6*d*. per lb., 20lbs. from each tree in one-year trees can be grown among coffee 15 feet apart without injuring the coffee, and say 190 trees to the acre would be Rs. 950 per annum from one acre of Croton trees after the 4th year, besides what income there may be from coffee or other produce.—Yours faithfully,

J. HOLLOWAY.

OUR FORESTERS.

(*To the Editor of the Ceylon Times.*)

SIR,—During my recent casual reading I came upon the following suggestive passage, which occurs in the Report of the Government Agent, Southern Province, for last year :—

"A careful examination of the few remaining forests in the province shews that almost all the timber of the valuable kinds is exhausted or only remains in quantities too small and too scattered to make it worth while to cut timber for the market. There is consequently a great want of good timber for bridges and buildings, and serious injury has been done by the general use for several years past of the inferior kinds of timber. The best remedy would probably be to draw for the present on the magnificent reserves of satin wood and palu in the North Central Province, and forms depôts for sale at convenient centres in this province ; and to provide for the future by forming plantations of teak and other useful timber."

"*Teak plantations.*—If timber plantations are to be of any future benefit, they must be formed with care and method, and not in the hap-hazard way hitherto adopted. The plantations in the Galle district are worthless : happily they are small and have not cost much. In Matara they are very much better, but until the last few months the trees have been put in too "far apart," and there is but little chance of their yielding fine large timber."

It appears from what I have seen during my travels in various parts of the island, that what is here said of the Southern Province is actually taking place in other districts. Government are milking their cow dry. They are evidently thinking only of current revenue and do not care for the future which will be left to take care of itself. What the Government Agent of the Southern Province says of teak may be equally said of all other building and useful timbers : the forests are being gradually and incessantly denuded, but no steps are being taken to replace what is destroyed or carried away. Instead of our speaking of a Forestry department, we should properly call it the Timber department.

X, Y, Z.

November 30.

TOBACCO.

(*To the Editor of the Ceylon Times.*)

SIR,—You will remember some four months since I sent you a few what I may call "practical hints about tobacco growing in Virginia,' since which you have had a good deal to say on this product. I am glad to find that you consider the sample of leaf received from the Eastern Province, so encouraging. You are mistaken in saying that irrigation is indispensable, the Jaffna method with the native tobacco is to irrigate ; and with a tiny plot of land under cultivation, no doubt it pays wonderfully, but on any large scale and particularly with Maryland tobacco, it is quite unnecessary, a moderate rainfall, and dry weather during curing time is all that need be asked. I shall be happy to send you estimates of tobacco cultivation by the Jaffna and Dutch systems. You will find that while the latter is the bigger outlay, it shews the larger profits, but my opinion is, it can only be tried on a small scale. I may say, roughly speaking, that it will cost Rs. 350 an acre for that Dutch method. It should of course, be borne in mind that Virginia tobacco only attained its present pre-eminence after many trials and failures and the greatest care and thought. In America, all caution is used in gathering of the plants only when the leaves are what is considered full ripe; and then only those which are so, are individually selected. The largest plants are split down the centre, so that the air may be freely admitted to every part of the leaf during the process of drying. And the greatest care is used in packing for the market.

Soil is no test of tobacco. Experiment and price can alone decide whether or not it is suitable. The quality of Havannah tobacco is said to depend mainly on the state and quantity of the iron in the soil. As with us, the soil both of Havannah and Manilla, are red sorts, and the red and reddish brown soils contain, most of them, iron—the reddish brown oxide of iron,—while the light grey soils contain it only in the state of protoxide, or the black oxide of iron. Again, the soil for tobacco in North America, and also in European latitudes, requires to be of the richest nature, but this is not necessary to the same extent in our warmer climate, and more moist atmosphere. In Virginia, the light red, or chocolate coloured mountain lands, the light black soil in the caves of the mountains, and the richest low grounds are particularly sought after.

It is thus evident that in Ceylon it is as yet a matter of experiment. We know of course that in the North, the Tamils make enormous profits by a *local* sale, but their tobacco, would not be looked at in the European markets. In certain parts of India, on the Ganges for instance, as well as in the Northern Circars, a most beautiful and aromatic leaf is grown ; yet the soil, from what one hears, is not to be compared to the rich and fertile valleys of Doombera or Badulla. The thing to work for, is a speciality. Once get a tobacco of fine and distinctive flavor, and your fortune is made. But the trial must always be attended with risk.

NIL DESPERANDUM.

AGRICULTURAL EXPERIMENTS NEAR POONA.

(*To the Editor of the Times of India.*)

SIR,—I have read with considerable interest, in your issue of the 26th instant, the account regarding Major Coussmaker's agricultural experiment's near Poona with the Teosinte (*Reana Euchlæna luxurians*) and johari seeds ; and as it is by universal assent conceded that the man who can grow two blades of grass where only one grew before is a benefactor of the human race, I think Major Coussmaker deserves thanks for putting himself to the expense and trouble of making experiments, and publishing the result for the information of the public and of men, like myself, who take a very deep interest in such matters. I have explained to the ryots, according to the best of my ability, Major Coussmaker's laudable object in making the important experiments he alludes to in his letter of November 20, and the following inquiry was made : "Ah, sahib, it was a garden experiment made by a sahib in comfortable circumstances, and with plenty of money at his command. You know perfectly well that we poor ryots, who are living from hand to mouth, and are deeply involved in debt, cannot afford to lose time in making fruitless experiments. The johari springs up vigorously in our cultivated fields, and if we are fortunate enough to get seasonable showers of rain, the plants grow in well-manured fields, to our satisfaction, and we have nothing to complain about, for we have no lack of provender for our cattle, and grain for ourselves ; but will you, sahib (piteously), explain to us what safe course we should adopt to preserve a johari crop when the rain falls at intervals ruinous to vegetation, no wells or manure being at our command, and while creditors' chains are hanging around our necks like mill-stones ?" I stood before the men dumbfounded, and retreated hastily, but promised to write to Major Coussmaker, through your columns of course for a solution of the ryot's difficulty, and

await with anxiety the receipt of a favorable reply. In conclusion, I may as well let you know that I am the occupant of some fields belonging to Government, and am obliged out of pity to suffering humanity to remit the asse·ement when, for want of rain, there is a miserable failure.

SYMPATHIZER.

Camp Ahmedabad, Nov. 20.

The Indian Agriculturist.

CALCUTTA, JANUARY 1, 1881.

DUAL CULTIVATION.

IN estimating the products of various crops in this country, as compared with the outturn at home, we are apt to forget that with the exception of land devoted to market-garden crops, the English soil is asked to yield only one harvest in the year. In India the rule is two, and we have known three crops raised within twelve months. It is not, however, of this double cropping that we would now speak; we desire to consider the subject of growing two crops simultaneously. It is sometimes done at home, as with hay and clover. In India, on the other hand, the custom is all but universal with certain crops. The reason for following this mode, as given by the cultivator himself is, that in the event of the principal crop failing, he falls back on the secondary crop; and there is doubtless a good deal of reason in this, as, the climate and rainfall of India being occasionally so fatal to certain crops, it may happen that a season, unfavourable to one crop, may bring on another. This, however, is only the ostensible reason, the real one being the inferior quality of the seed frequently used; for when a double crop is sown, it does not follow that only half the ordinary quantity of seed of each grain is sown. By no means. Each crop is sown as if it were the only one to be put down, and it would be a bad sign of the seed, if something like a crop should not result. Another reason and a good one is, that frequently the farmer wishes to cut his crop green for cattle food, and as the two crops sown together do not ripen synchronously, the farmer has a longer spell of green fodder. Whatever the reasons may be, of this we may be sure—that the practice is not a good one. The farmer foolishly imagines that he gets two crops out of the ground, but mother earth is not to be taken advantage of in this crooked way. Every crop grown withdraws certain ingredients—certain elements of plant food—from the soil. No two crops withdraw exactly the same class of plant food, or to the same extent; consequently, it is possible to get a heavier weight of grain or straw from two crops grown in this way, if they are selected with a view to prevent clashing in their feeding, if we may so put it. At the same time it must be borne in mind that this is only achieved at the cost of more rapidly impoverishing the soil, and disturbing the natural proportions of those elements which should be held in all good soils. Nature in this as in all other excesses is inexorable. If we make too many demands on her, she may reply for a time, but only for a time, as a period speedily arrives when the yield stops, or only appears in very diminished quantity. Let us be sure of this: if we over-work ourselves, we shall feel a reaction afterwards, and if we make Nature do too much in the way of production, she will have her revenge in some form or other. It is a fatal mistake to suppose that two crops can be obtained in this way at the cost, so far as plant food is concerned, of only one. If the crop is a good one, the soil is proportionately weakened, that is, presuming that manure is only given in the perfunctory manner peculiar to India. Where high cultivation is followed, the result will of course be very different. One more great objection and we have done. Dr. Forbes Watson in his interesting report on Indian wheat, tells us that in a vast proportion of the samples sent to England to be reported on, foreign matter and other grains were present. The former was caused doubtless by the primitive mode in vogue for threshing out the grain, which makes it hardly possibly to avoid incorporating particles of clay and pebbles with the newly threshed grain: the latter was in most cases due to this dual cultivation, and the difficulty that exists in harvesting the two crops separately. They are cut one at a time of course, but ears of one will get mixed up with those of the other, in spite of the greatest care. If the Indian cultivator would meet the American farmer in the struggle now going on in connection with the wheat supply for the United Kingdom, he will have to conform more to modern customs, and present his produce in that clean and pure state which alone will find for it a chance of a market.

ON GUTTA PERCHA.

ITS HISTORY, PREPARATION, AND CULTIVATION.

[*By James Collins, F. B. S. Edin: Honorary Member of the Society of Pharmacy of Paris, etc. Government Economic Botanist, Singapore. Author of "Report Caoutchouc of Commerce" to H. M's. Secretary of State for India.*]

THE early history of gutta percha is involved in some obscurity. The first notice I have come across of its appearance in England, is contained in John Tradescant's Catalogue of the "Rarities preserved at South Lambeth, near London" (1666). No trace of this "plyable mazer wood" as it is there described, can be found at the Ashmolean Museum at Oxford, of which museum the collection of Tradescant was the nucleus. This connection between gutta percha and the old historic "mazer cups" is a highly interesting one, and it is by no means impossible that the "mazer cups" described by Spencer and others, were at times made of gutta percha as a substitute for maple. Curiously enough Dr. Balfour gives "mazer wood tree" as one of the vernacular names of the *Isonandra gutta* (now *Dichopsis gutta*).

To Dr. Wm. Montgomerie, a Surgeon in the East India Company's Service, belongs the honor of first introducing gutta percha to the commercial world, as an article likely to prove of great utility in the arts and manufactures. He first noticed the substance in Singapore in 1822, in the form of whips, and there commenced his first experiment. In 1842, being again stationed at Singapore, he followed up the subject and recommended it to the notice of the Medical Board of Calcutta for the making of splints and other surgical appliances, which recommendation the Board highly approved of. He also sent specimens and information concerning this substance to the Society of Arts of London. This Society took up the subject most warmly, and on Dr. Montgomerie's return to England in 1844, he lectured on the subject, and was honored with the Society's gold medal. By some, the honor of introducing gutta percha to the notice of the commercial world is claimed for Dr. (afterwards Sir) José d' Almeida, who in 1843 sent a specimen as a *curiosity* to the Royal Asiatic Society of London, but, after careful comparison of dates and other materials, priority is most clearly in favor of Dr. Montgomerie. In some of the earlier journals the Society of Arts of London is accused of injustice in passing altogether over Dr. d' Almeida, the allegation arising in confounding that Society with the Royal Asiatic Society of London. Dr. d' Almeida as I have said, only looked upon the substance as a *curiosity*, whilst Dr. Montgomerie was impressed with its great commercial utility and took the most effectual means to bring it before the public. The action of the Society of Arts soon brought the substance prominently forward, and patents were speedily taken out. Nothing, however, was known of the botanical history of the plant till Mr. Lobb, a Collector in the service of the Messrs. Veitch, the eminent nurserymen, forwarded a specimen to Sir W. J. Hooker, who named the tree as *Isonandra gutta*. Mr. James Motley also paid much attention to the subject whilst at Bangermassing, and Dr. de Oriese published a list with descriptions of no less than 10 plants yielding this substance. Unfortunately the collections of Dr. de Oriese, which I examined at Leyden, do not solve the question as to how to identify the products with the plants producing them.

Gutta percha, as it appears in commerce, is of a reddish or yellowish hue, nearly as hard as wood, receiving more or less readily the impression of the nail, and of a porous structure. When cast or rolled it assumes a fibrous structure and acquires a tenacity in a determined direction. At a temperature of 32° to 77° Fahr., it has as much tenacity as thick leather, but is not at all elastic and less flexible. In water towards 120° Fahr.,

it softens and becomes doughy, although still tough; at 145° to 150° it becomes soft and pliant, and in this state it assumes all the elasticity of caoutchouc, but does not retain it long as it becomes again hard and rigid on cooling. It is highly inflammable and burns with a bright flame, and has electrical properties in a high degree. Gutta percha, like many other milky juices, is found in the *Cinenchyma* or *Laticiferous* tissue; a series of tubes forming an irregular network, and found in the greatest abundance in the middle layer of the bark. By this it will be seen that to get at the milky juice it is only necessary to cut through the *bark* as it does not exist in any appreciable quantity in the wood itself.

The question of the native names of the different varieties of gutta percha is most important; yet each district has often its own peculiar name, and many of the names we may mention may yet prove to apply to the same tree. As to the term "gutta percha," in spite of what has been urged by Oxley, Logan, Seemann, and others, it has now become a collective or generic name, and must be received as such. On the other hand the term "gutta taban" is *not* a generic term in any sense of the word, but is the name of a particular variety. The following is a list of some of the varieties of gutta percha, together with the localities where found, and the scientific name, where known :—

1. * Gutta Taban, Percha, Niato, Durian, Balam timbago, Dadauw [*Dichopsis* (*Isonandra*) *Gutta.*]

This tree grows in Malacca and the Malay Peninsula generally, Sumatra, Borneo, &c., and attains a height of 60 to 80 or more feet, with a diameter of 2 to 4 or 5 feet. The leaves are universally egg-shaped and entire, pale green on the upper side, and covered beneath with short reddish-brown and shining down. The flowers are arranged in clusters in the axils of the leaves. The fruit is eaten and a vegetable butter prepared from the seeds. There is also a variety named *oblongifolia* found in Borneo.

2. Ngiato putih (putih-white) (*Dichopsis macrophylla.*) Yields a second rate gutta. Borneo.

3. Kotian (*D. Motlleyana*). Used for adulterating better kinds.

4. Benton (*Payena dasyphylla*). Second rate gutta. Borneo and Sumatra.

5. Percha Waringin. Under this name the best variety of gutta is known on the Kapuas River in Borneo.

6. Nettu. A second class gutta. Borneo.

7. Ploot. A third class gutta, Borneo.

8. Kalapeich lanyut. Said to be the name of the very finest we receive. Borneo.

9. Kalapeich Mookas. Next in quality to No, 8. Borneo.

10. Kalapeich Kapur. Not so good as No. 9. Borneo.

11. Daging. Gutta Daging comes nearer to Balata than any other substance I have seen in the Malayan Archipelago, and might be used for the same purposes. "Daging" means "flesh" and well describes the gristly character of this variety. Malay Peninsular.

12. Muntah. Getah Muntah means "raw" or "unprepared gum," and the term is equally applicable to the unprepared gutta of every variety. It may be of the best quality or of the very lowest kind; whichever it be, if not prepared speedily it loses all its value by becoming resinified.

There are, beside the above, many other species of the genera *Dichopsis Chrysophyllum, Sideroxylon, Mimusops,* &c., which yield gutta percha, but have not been determined yet. There are also many native names of other varieties, but as their qualities are very inferior and used only for adulterating better qualities, it is needless to mention them here.

As to the climatic and geographical distribution of the trees yielding Gutta Percha, it may be stated that the trees are very restricted in their natural habitat, that is to say, between 6°N. and S.L. and 100° to 120° E. L., whilst the finest varieties are said only to be found between 4°N. and 3°S. with a temperature whose outside limits are 66° to 99° Fahr., and a very moist atmosphere. These limits are well within the Isotherm of 80° Fahr. All accounts agree that gutta percha trees flourish best in a moist temperature, in light loamy soil at the foot or slopes of hills and surrounded by primary (*not secondary*) jungle.

* All the native names are prefixed by the Malay term "Gutta" which means "gum."

As Gutta Percha trees are indigenous to Singapore (although only two or three trees are now to be found on the island) a slight sketch of the climate may be interesting.

The Singapore year may be divided into three periods of four months each :—

1st. From January to April, during which the rainfall is very variable and uncertain.

2nd. From May to August, which may be called the *dry season*, and is the period, as a rule, in which the rainfall is least.

3rd. From September to December, which may be called the *wet season*, and during which, as a rule, the rainfall is greatest.

The total yearly rainfall for 1869 to 1873, furnishes the following figures :—90·63, 123·24, 109·45, 75·30, 85·60. For the same period the thermometer gave, highest :—92°, 93°, 91°5', 92°, 92°5', and the lowest as :—69°, 69°, 67°, 68°5'.

The collection of gutta percha generally takes place directly after the rainy season is over, as in the dry season the gutta does not flow so readily, and during the rainy season the collectors are more liable to attacks of ague and jungle fever, and often when cutting down a tree a heavy rain will wash away the gutta as it flows out. At times the collectors go in companies, often receiving advances in money, cloths, food, and tools, to be afterwards deducted from the proceeds of their expedition, although cases are not unknown where the trader who makes the advances loses principal and interest from the non-success, death, or knavery of the collectors.

The yield of a well-grown tree of the first or best variety is from 2 to 5lbs. of dried gutta, such a tree being about 30 years old, 30 to 40 ft. high, and 30 inches to 3 ft. in circumference. A full grown tree of 100 to 140 ft. to its first branches has been known to yield 50 to 60lbs. of gutta. Gutta, however, unless most carefully prepared, loses within 6 months 35 per cent. of its original weight.

The method of extracting gutta percha, is much the same amongst the Malays, Chinese and Dyaks. The trees are cut down just above the buttresses or *banees*, as they are called; a staging being erected for this purpose. The tools used in felling are either "billiongs" or "parangs." A "billiong" is a chisel-like axe lashed to a handle by means of rattan, although Chinese axes are sometimes used, and are regularly 'wedge' shaped. A "parang" may be described as a long bladed knife or sword. As soon as the tree is felled the greatest haste is made to lop off all the branches, the natives asserting that if this is not done all the gutta would ascend to the leaves. The next operation is to cut and remove narrow strips of bark about one inch broad and about 6 inches apart. These cuts do not extend all round the tree, the under part of the tree being buried in the soft earth in its fall. Some natives also strike the bark with mallets in order to accelerate the flow of milk. The milk, or gutta, flows slowly (changing colour as it flows) and rapidly concretes, and is of a different colour in different varieties, varying from a yellowish white to a reddish or even brownish tinge. The gutta as it flows is received in hollow bamboos, doubled-up leaves, spathes of palms, pieces of bark, coconut shells, or even in holes scraped in the ground. Only two-thirds of the gutta is thus extracted, as one-third is buried in the ground. If the quantity collected is small, it is prepared on the spot by pressing it together in the hands into a mass, or making a hole or loop in the mass to carry it by. Often it is sent into the market in this state, and is then known as "raw gutta," "white Borneo" or "gutta muntah," the latter word meaning in Malay, "raw or uncooked." If water gets into the milk the gutta becomes stringy and is considered deteriorated, but after boiling appears to be quite as good. Sometimes the gutta is kept in a raw state for a month or two, before undergoing preparation by boiling, but I firmly believe that to preserve the gutta in its best state, the gutta should be boiled *immediately* after collection. The boiling is generally conducted in an iron pan or "kwali," either cast or wrought, about fifteen inches in diameter and six inches deep, with two handles riveted on. Those of Siamese manufacture are generally preferred. The boiling is either with simple water or with water to which lime-friut juice or coconut oil is added. It is said that if about one pint of lime-fruit juice is added to three gallons of gutta milk, the latter congeals or coalesces immediately on ebullition, and that this addition expedites the preparation very materially.

When the gutta arrives at the port of shipment, before it is exported, it generally undergoes an examination and classification into suitable parcels, according to quality. As it is received it presents great diversities as to appearance, shape, size, and colour ; from crumbling, hardly coherent, whitish or greyish "raw" or gutta muntah fragments, to hard reddish or brownish blocks as hard as wood. Sometimes it is made up into all manner of grotesque representations of animals, and nearly always adulterated to a large extent with sago-flour, saw-dust, clay, stones, &c. The Chinese are great adepts at classifying and assorting gutta, and frequently "reboil" the gutta, by mixing small parcels of different varieties up to a certain "standard sample." This is done by cutting or chopping the guttas into thin slices and boiling in water in large coppers, keeping the gutta constantly stirred with poles, and adding good gutta and even cocoanut oil to give the product a better appearance. When sufficiently boiled, the gutta is taken out of the pans, pressed into large moulds and is then ready for shipment.

The imports of gutta percha into the United Kingdom amounted to 26,359 cwts. in 1877, valued in the Board of Trade Returns at £238,327, and the Market prices per lb. during the six months ending January 1878, ranged from 6*d*. to 2*s*. 9*d*. according to quality and freedom from adulteration and admixture.

(*To be continued.*)

REVIEW.

"NEW COMMERCIAL PLANTS WITH DIRECTIONS FOR THEIR GROWTH AND CULTIVATION."*

THIS publication supplies a long felt want and fills up a most important gap in commercial literature. It is well known that there are vast numbers of plants which have been proved to be of great use, but their usefulness not being generally known and only noticed in some scientific journal or report, the plant continues to "blush unseen." Those who have had to study the history of any new product which suddenly comes into the market and proves itself of great practical utility, are often struck to find in some ponderous tome, a full account of its uses and properties, published years and years previously. The object of the publication under review is to bring together the scattered literature likely to further the cultivation of plants for purposes of agriculture, horticulture, and medicine, and the manufacturing arts generally. In the numbers before us we have notices of the Liberian Coffee, African India-rubber, Turkish Tobacco, Chaulmoogra Oil, Mahwah Tree, Cocoa, New Forage Plants, and amongst many others a notice of the well-known Papaw Tree, about which so much has been written lately that we trust to return to the subject in an early number. Each notice treats of the operation of sowing, method of cultivation, management and preparation for the market, and the more important plants are illustrated with capital plates.

As to the commercial aspect of the question, that of supplying seeds and plants, Mr. Christy must be complimented on his pluck. The obtaining of new plants for experiments in acclimation has generally been looked upon as a State duty, as the costliness of expeditions are generally beyond the means of private planters. Nurserymen as a rule fight shy, and if one appeals to a Botanic Garden, he generally finds that only one or two (if any) examples are to be found. Still, many planters have a piece of spare ground, and if a few plants were purchaseable at a moderate rate, many too would like to experiment for themselves. In sending cases of plants say from America or from Africa, one great cause of mortality has been that they were sent to England first, before transmission to India. This, Mr. Christy has arranged to remedy by means of his agents who send direct to the ports where they are required. Altogether the scheme is a good and sound one and should prove of great practical utility.

The publication should be in the hands of every one who takes an interest in the subject, and we trust that it will not be long before another number is issued. The information contained in these first three is reliable and trustworthy,—praise that can so seldom be truthfully bestowed.

* By Thos. Christy F.L.S., London, Christy & Co. Nos. 1, 2, and 3, pp. 38, 14, 40, 1878-80. 8vo.

EDITORIAL NOTES.

AN esteemed correspondent from Burdwan writes us on the subject of the introduction of the American plough into India. We are sorry we cannot find room for his lengthy letter. We shall, however, give him what information we have on the subject. The American plough has in our opinion four drawbacks. It is too heavy ; it is too costly ; it has two handles instead of only one ; and it is so foreign in general appearance to the ordinary *hul*, that its adoption cannot fail to be hindered thereby. What is wanted in India, is an improvement of the ordinary country plough, and this is being attempted with success we believe. If our correspondent has ever watched a native ploughman endeavouring to guide a double-handled plough, he will see at a glance what we mean ; that the difference between that implement and the ancient Indian *hul*, is fatal to its introduction. There are several improved native ploughs in the market at present, and we would advise our correspondent to give them a fair trial before investing in foreign implements.

DR. W. W. HUNTER recently delivered an interesting lecture upon India, which may be regarded as in some sort a counterblast to the exceedingly optimist addresses which he delivered last year. Those who have lately made so much fun of Mr. Caird and his careful criticism on the present condition of our great dependency will perhaps be a little surprised to find that Dr. Hunter, an official of officials, and now Director-General of Statistics to the Government of India, takes almost exactly the same view of affairs as the much-ridiculed Famine Commissioner. It is impossible, indeed, to glance through Dr. Hunter's grave statement without being struck with the fact that they justify almost everything that has been said by the writers of the so-called pessimist school. For Dr. Hunter tells us that the population of India has increased to an enormous extent under our rule, and as a result "the husbandman has now to wring a subsistence out of inferior lands which he would not have touched 100 years ago ; the good lands have deteriorated for want of manure and want of rest, and the cattle have degenerated from lack of pasture. The result is that the cultivator gets a smaller average return for his labour, and in this way the struggle for life has been rendered more severe to masses of the population." Dr. Hunter will not say with the facts before him, the "the case is hopeless ;" but we have not yet discovered, or at any rate applied, the remedies. The low standard of comfort seems, as in Ireland, and as we have sometimes seen in times of depression in our great cities in England, to increase the expansion of population. In the Native States, which enjoy equal peace with our own territory, thanks to our supervision of the whole country, this same pressure of the population on the means of subsistence is not felt. For whereas the average population over the greater part of our territory is 243 persons to the square mile, in the Native States there are but 89 persons to the same area. It is indeed, but too true, that we are standing aside and watching "the pitiless operation of economic laws whose force no man can stay." Not at once ; but the effects Dr. Hunter has noted come, as he himself points out, by cause.

IN the official year 1879-80 the Pegu province (British Burmah) exported 728,384 tons of rice, husked and unhusked, to foreign countries, as compared with 648,594 tons in 1878-79 and 579,770 in 1877-78. This increase is satisfactory, and as population increases, new lands are taken up, whilst additional rice-mills, worked by steam, are every year being erected in nearly all of the principal ports. We may confidently expect that we shall soon witness a million tons annually shipped to foreign countries, seeing that Burmah rice is in greater favor with consumers than Siam or Cochin China grain. The removal of the export duty of three annas per maund would doubtless at first tend greatly to stimulate the export trade, whilst higher freights and advanced prices paid for grain would probably soon make up the cost to the consumer in foreign countries to the present rates. The opening of the Suez Canal has done a good deal for Arracan grain, which, being softer than the Pegu description, does not stand a long sea voyage so well as the grain exported to Europe from Rangoon.

EUROPEANS who have not been in Burmah have perhaps never seen the "glutinous rice," the sale of which at the Yandoon bazaar was recently stopped by Mr. Fox, Assistant Commissioner, for the ostensible reason that its use when cholera was about, was dangerous to the public health. This glutinous rice or *kouknoen*, as it is called throughout Burmah, is what nine out of every ten Burmese houses begin their daily food with. It is very often cooked in bamboos, and forms, with a little scraping of cocoanut, a very filling meal for *chota hazree*. A Burman proceeding on a short journey will not take the trouble to carry cooking chatties with him, nor would he think it worth while to cook curry and rice when, for two pice, he can get a full meal of *kouknoen* which will satisfy and nourish him at the same time. To a European unaccustomed to its use, this glutinous rice would doubtless be indigestible and insipid, but how can we imagine that a grain so universally used by the Burmese is bad for them. One shipment of glutinous rice was made, we believe, some years ago from Rangoon to Europe by one of the local firms. We presume the result was not a commercial success, as it seems never to have been repeated; but now that steamers deliver their cargoes from the rice ports in 40 days from the date of shipment, it might be advisable to try it again, as we should think, from the favor with which glutinous rice is received by Burmese, it must contain greater nourishment than any other description of rice exported, and would doubtless at home be used for biscuits, puddings, &c., to a large extent if it was more generally known.

THE world is crowded with plants not as yet fully utilized. It is the charm of Chili, says a South American journal, that somewhere within the country so many products of widely different lands will thrive and be at home. Horticulturists should always give their attention to whatever appears worth planting on a small scale, to test in hope of a wider future. Among these there is the Anuatto plant *Bixa Orellana*, which grows in the valley of the Amazon. It is seldom over 12 feet high, and forms a round bush having heart-shaped leaves. The dull red fruit is covered with prickles, and grows on the tips of the limbs; and each fruit contains about 50 seeds, covered with red pulp. In another and hardier variety growing in portions of Peru, the fruit is yellow. The flowers of both species are handsome, and the Bixa would form an interesting shrub for the lawn. The seeds are tied up in little bags and dipped in stews. The seeds are used to make a dye, and are worth 40 dols. to 50 dols. a barrel. Some years ago the editor of the *Florida Agriculturist* distributed a quantity of seed in that State, but we do not know with what success. Decidedly, however, it is advisable to try Anuatto on this coast.

THE fuel question in the Darjeeling district has become a most serious one of late years, says the local paper, and especially with regard to firing tea. It is true that several machines for thoroughly drying tea and at the same time economising fuel have attracted the notice of planters of late years, and although much has already been done in this direction, all the drying machines hitherto tried in this district are, we are sure, susceptible of very great improvement as regards cheapness, economy of fuel, and drying capabilities as regards capacity to fire off an increased amount of withered leaf in a given time. We have no doubt but that in the course of a few years all needed improvements, will be effected, and we look forward with confidence to the not very remote future, when, with some perfected tea-drying apparatus, the tea planter will be able to dry his hundred maunds of leaf a day with an expenditure of about five maunds of fuel.

Now that bone has come into such great requisition as a manure for coffee, a large trade in bones is carried on between the bone crushing establishments in Beypore, Calicut, and elsewhere, and traders in all parts of Southern India. The bones are forwarded in a whole state, generally, and broken up afterwards at the crushing establishments. The bones used we need hardly say are those of animals and birds which have either died, been slaughtered, or fallen prey to wild beasts. But the other day a case occurred, the *Bangalore Spectator* informs us, in which human bones were consigned as manure. A firm at Beypore requiring a large quantity of bone for manure, a native at Gooty consigned to them by rail a number of human skeletons, in pieces. The bones had evidently been dug out of some pit in which victims of the late famine had been buried. The trainage alone on the consignment, amounted to some two hundred rupees, it would seem. On arrival at Beypore, the firm to whom this ghastly freight was consigned, had the same thrown into the sea. Some of our modern philosophers, however, would be inclined to argue that human bones could not be better disposed of than as manure.

WE may expect, obcrves the *Civil and Military Gazette* that the introduction of agricultural banks will find an early place among the commercial and industrial questions to which Lord Ripon hopes to devote the better part of his Indian career. It would be difficult to conceive a plan which, if intelligently carried out, would confer greater benefits on the cultivating classes. The germ of the institution in fact exists in the present system of tuccavi advances; but there is by no means a general agreement, among writers on the subject, that agricultural banks should, like the *tuccavi* system, be purely and solely under Government control. As is well known, the utility of the latter is seriously impaired by formalities rather perplexing to the uneducated peasantry for whose benefit it has been invented. Speaking for the Bombay side, a contemporary believes that agricultural banks lending at five per cent. would, if carefully managed, yield a very fair dividend to their shareholders.

THE trade in jute has shown great expansion. The exports in 1854-55 were valued at £229.241, while in 1879-80 the value of raw jute exported was £4,370,032, and of jute manufactured into gunny bags £1,091,366.

SELECTIONS.

THE TODDY PALM.

THE local Government has before it a recommendation from its Board of Revenue, to encourage the more extensive cultivation, in these provinces, of the toddy palm. The recommendation appears to us worthy of serious consideration on several grounds, not the least being the probability of a considerable increase of revenue. The toddy palm grows easily enough in many parts of these provinces, and its toddy, or *tari* as it is called in excise phraseology, is, according to native ideas, the least injurious of country intoxicants. The tree certainly takes a considerable number of years to attain a size at which it can be tapped without serious injury to its vitality, but in the long run it must yield a not inconsiderable return. Its rate of growth and longevity vary under different climatic conditions, but in the central *duab* of these provinces it is believed that it may be tapped properly (this is often done earlier) in its twenty-fifth year, and thereafter in two out of every three years, for from thirty to fifty years more. Considering that this species of palm tree, when standing singly, throws no shade injurious to crops, that it will grow on any odd scrap of ground (in ravines for instances, where, nothing in the shape of a crop is possible), that once established it needs no further care, and that if grown plantation-wise it can, and with advantage to the trees, be grown as close as from 40 to 50 trees to the acre, its growth might, it would seem, be advantageously encouraged, and in its arboricultural operations Government itself might in some places set the example. The tree yields in abundance a popular and comparatively innocuous beverage, which can be sold very cheap, and the duty on which would, the Board thinks, swell the revenue of the province materially with the least possible harm to the people. It would also, at one season at any rate exercise an effective check on illicit distillation. Toddy, or *tari*, to the natives is what beer is to Englishmen, as compared with spirits. Many people drink *tari* who do not drink spirits, and it is very doubtful whether even a very large increase in the sales of *tari* would very much affect the sale of *licit* spirits, though, as the Board thinks, it certainly would affect that of the weak home-made illicit liquor.—*Indian Herald.*

JUTE IN EGYPT.

REFERRING to the movement for the cultivation of jute in Egypt, the *Egyptian Gazette* says that it seems probable that the soil and climate will prove favourable to the plant. Some Bengalee coolies are expected to arrive shortly to teach the fellaheen not only how to cultivate the plant, but also how to separate the fibre. Jute will present to the Egyptian agriculturists, says our Alexandria contemporary, many advantages over cotton. It occupies the soil only four months instead of eight or ten like the last-named plant. The cost of cultivation is proportionately less expensive, and the process of reaping, steeping, and separating the fibre can all be completed in less than a month by the fellaheen. In consequence of the shorter time that jute occupies the land also, its cultivation is less exhaustive to the soil than that of

cotton. If jute can be cultivated on the saline marshes, the importance of the result will be very great, as a considerable part of Egypt consists of such lands, which it has been found impossible to utilise hitherto. In Bengal, jute flourishes in similar positions, but it must be admitted that the soil is not there saturated with salt to nearly the same extent as in Egypt. The Dundee manufacturers will be glad to have an alternative source of supply besides Bengal. Mr W. Grant, who has been engaged in promoting jute culture in Egypt, stated in a report published by the Egyptian Agricultural Society a few months ago, that where the experiments had been conducted intelligently and under favourable conditions, the plant has attained proportions unknown in Bengal. The *Gazette* considers that the more or less successful cultivation of jute in Egypt is, in fact, assured. The proximity of Egypt to the chief consuming countries will, of course, give the Egyptian cultivators an advantage over those of Bengal in the items of freight and insurance charges for carriage to the markets.

THE KULSI AND CHARDUAR PLANTATIONS.

CAOUTCHOUC growth in these plantations has been on the whole very successful for the year under Report. In the former 45 strong and healthy seedlings (two rows) were planted out from the seed nursery of the previous year, and their flourishing condition is directly attributed to the soil which is found to be of a better quality than that of the older compartment. Six seed-beds, aggregating 915 sq. feet, were prepared in the usual way, and 5 seers of seed collected in Gowhatti; when sown it germinated 4,000 plants. Of these, however, one-fourth have since succumbed from various causes, leaving about 3,000 plants alive at present, besides 328 cuttings made in December 1879. As in previous years the deer have contrived to do considerable damage to the younger seedlings, while in March last a herd of twenty wild elephants which passed through the plantation, caused great havoc, destroying no less than 28 fine trees, while pigs have also occasionally made their way through the fence; but the damage on the whole has been less than in former years. In the Charduar plantation no extension has been attempted, although the new compartments (composed of 2,747 mounds thrown up in the first eight) are ready to be planted. In addition to this 4,521 seedlings have been transplanted from the nursery into the plantation where the growth of the plants has been vigorous. The fencing, which has been strengthened by an additional line (round the interior) of three-year old cuttings, has answered the purpose very well, but the deer have proved themselves if anything, more troublesome than previously. Laxity on the part of the forest guards set to watch has also tended to increase the inroads of deer and other wild animals.

There is no doubt that keeping the deer out of the plantation is the only difficulty remaining in the growth of caoutchouc trees: and, as last year's experience has shown, the fence instead of lasting three years will not last longer than two.

It has been found by experience that trees several years old can be transplanted with as much safety as younger trees, and the Conservator has arrived at the conclusion that plants must remain in the nursery much longer, until they have reached such a size that deer can no longer harm them. By doing this, it is hoped to be able to do without any fencing, and, although the transplanting of such large trees will be more expensive and the cost of nursery work be double or treble of what it is now, all this will be more than counterbalanced by the saving in the cost of fencing.

The expense of moving trees can further be reduced to a minimum by having a separate nursery for each compartment. Nothing certain however can be said until this method has been tried, and meanwhile regular hunting of the plantation by Miries with trained dogs has been started, and by this means the deer are kept down.

TREES YIELDING INDIA-RUBBER.

CENTRAL American Rubber Tree.—(*Castilloa elastica.*)—1. *Locality, Soil, and Climate.*—The very extensive geographical range of this tree shows it capable of existing under considerable varied climatic conditions. The forests in which it grows are usually at or near sea-level, but it has been observed at an elevation of 1,500 feet on the Pacific coast. The soil varies, but the plant avoids marshy or boggy land, appearing to prefer warm deep loam or sandy clay, and especially affecting the margins of small running streams where it grows in little groups. A dry or a rainy climate seems equally suitable, but a high and equable temperature, which does not sink below 60° F. at any time, is essential.

2. *Propagation and Growth.*—This is a very much larger tree than those above described, being, when fully grown, of the imposing height of 160 to 180 feet, with a stem of 12 to 15 feet in circumference. It grows very rapidly. At Henaratgoda at two years of age it was 23 feet in height. The bark is thick, and the wood soft and readily decaying. We received but a few plants of this species in Ceylon, and have had little experience in its management. No flowers have been yet produced, and Dr. Thwaites did not find cuttings of the ordinary kind to succeed well. We are now, however, endeavouring to propagate at Peradeniya by various other methods.

Mr. Cross has the following remarks:—"Trees in good situations will produce seeds early, but these will require to be planted without delay, as drying destroys their vitality." The tree is stated to flower in January and the fruit to be ripe in April. "Stout branches cut into pieces each possessing a bud and covered lightly with soil, will generally be found to grow. Strong cuttings a foot in length and furnished with buds, when planted in the usual way, will become strong plants sooner. However, the propagation of this tree will not be found so easy as the Ceara rubber. In the planting out of young plants, the petiole or leaf-stalk of the lowest or oldest leaf should be buried in the soil. By following this simple rule the plant commences to grow at once, its growth is vigorous, and the trunk symmetrical. But if at the period of planting there is much bare stem above ground, then growth is usually slow, the plant remains 'leggy' for some time afterwards and never makes a good tree. The plant has a curious habit of dropping its young branches, which disarticulate by a regular joint, like deciduous leaves, and leave a clean scar on the surface of the stem. From what has been said above as to its native sites, it would seem that our south-western coast would present many favourable localities for this valuable tree.

3. *Collection of the Rubber.*—Milk is abundant and flows readily, but it is of a somewhat more watery consistence than that of the Para rubber. In consequence of the large size of the trees it is the practice of the collectors in Panama and other parts to cut them down. A groove or ring is first cut round the base of the trunk and the milk received into large leaves. "The tree is then felled, and rings or channels are cut out around the prostrate trunk at about twelve or fourteen inches apart," and the rubber allowed to run into leaves or vessels. In Nicaragua the trees are tapped with sharp axes in various ways, and the trees so much injured that the process is performed at intervals of three years. The milk is received into iron pails. It does not appear that this species is tapped until it has a diameter of sixteen or eighteen inches, which Mr. Cross thinks might be attained in six years.

In conclusion, a few words may be said about the preparation required to fit caoutchouc for the market. It is clear that mere exposure to the air is sufficient in some cases to effect the coagulation of the milk into a solid mass. This is all the preparation apparently that the Ceara rubber receives, which comes into the market in bales consisting of the rolled up strings pulled off the trees. But it seems that a decomposition is liable to occur in the milk if exposed in any quantity, and it is usually desirable to reduce it to a solid mass as quickly as possible. For this purpose the cautious application of dry heat is the best; the best Para rubber is prepared by being poured over a flat paddle-shaped mould, which is held in the thick hot smoke from burning wood and palm-nuts till it solidifies, then slit down one side, the mould taken out and the "biscuit" hung up to dry. In several parts of Central America coalescence is effected by the addition to the milk of the juice of certain plants (especially of *Calonyction speciosum*, which is a common Convolvulus here in Ceylon). This causes the separation of the caoutchouc, which floats in the liquid like a mass of soft cheese, and has to be pressed and rolled to get rid of the fluid still remaining in its substance.

Probably carefully conducted evaporation in shallow pans by artificially regulated heat would be found an effective method.

The purity of the prepared rubber being a matter of first importance, all pieces of bark and earth should be removed by passing the milk through sieves. Small pieces or thin sheets of caoutchouc are preferred to large masses in the market from the facility of estimating the purity of of the article.

Absolute dryness of the rubber is also a point requiring the greatest attention, and may require hydraulic pressure for its thorough attainment.

As much as 129,163 cwts of caoutchouc were imported into England in 1874, of which 70,866 cwts were American and obtained from the plants here under consideration. The value of this latter was £1,007,413. The demand for the best sorts is constantly increasing. On the relative market values of the various kinds of India-rubber, reference may be made to the excellent "Report on the Caoutchouc of Commerce" by Mr. J. Collins, and printed for the Indian Government in 1872, to which I am indebted for some of the above information, and to a paper by Mr. C. R. Markham in the *Journal of the Society of Arts* for April 7th, 1876.

I may be permitted to add that it is gratifying to reflect on the prominent share which the Royal Botanic Garden at Peradeniya, under the care of my distinguished predecessor, Dr. Thwaites (as detailed in his Reports from 1875-1878), has taken in the acclimatization of these valuable trees of the western hemisphere in Burmah and India; where as well as in Ceylon, it may be confidently expected that they will become a valuable source of revenue.—*Henry Trimen, Director, Royal Botanic Gardens, Peradeniya*, in *Journal of Applied Science.*

REFORM IN OUR AGRICUTURAL FARMS.

A PERUSAL of the annual reports of the Government farms scattered over the country and maintained at rather heavy cost, will convince one that we are going the wrong way to work in the matter of agricultural improvement. We open out a farm, and at once appoint a highly paid officer to look after it. This officer may or may not be a practical agriculturist; he may not even possess a spark of enthusiasm

for his work. Nevertheless a place has been found for him, and there we find him year after year producing a much smaller outturn of grain than the rayats around his farm. We read, for instance of an eminent agriculturist in charge of one of these farms, speaking quite complacently of his outturn of 33lbs. of cleaned cotton per acre, and of 300lbs. or under four maunds per acre of jowari after years of experimenting. With results of this nature we are pretty sure to be asked in the Resolution on the report, why it is that the rayats will not learn at these farms. A few seconds' reflection would tell any man that the rayats do not wish to learn how to produce a crop of 300lbs. of jowari or 33lbs. of cotton per acre. The cultivator usually sells his cotton crop at about 5lbs. per rupee, so that this crop may be worth gross about seven rupees while it will have cost him ten to twenty rupees to cultivate it. One farm in the west recently produced 521lbs of cotton per acre, and how another Superintendent can placidly sit down and acknowledge to having made 33lbs. per acre passes our comprehension. If our farmers are ever to benefit by such experimental operations, they must be conducted on principles compatible with common sense. We must show the farmer, in a manner not to be doubted, that if he spends one rupee extra in manuring, irrigating, or deeper ploughing, he will assuredly receive two in return, and this must be no theorizing. We must actually spend that rupee and earn the other two before his very eyes. Then he will believe; but what is he to think when he sees a great Governmental institution presided over by a highly paid and presumably well qualified officer spending sums of money quite beyond his power, and obtaining worse results than he, with his impecunious position and primitive means of culture? He naturally supposes that his own old fashioned plan is the best after all. This is the point where Sir Ashley Eden's remarks must have told with effect. He complained that nothing of a satisfactory nature resulted from the pretentious efforts being made under Government patronage, and there is a deal of truth in the remark. Year after year we have voluminous reports of what has been done, and how climatic influences prevented the achievement of better results, but what do we learn that is of any practical benefit? Absolutely nothing. The dilettanteism which is characteristic of much of our official work is clearly seen here, and here, if anywhere, we want practical men and practical measures. There is little use in pointing out the patent fact that the rayat is ready to follow new ideas and new methods; he must first of all be convinced that they are improvements on the old.—*Englishman.*

EXPERIMENTS WITH INDIAN WHEAT.

(To the Editor of the Times of India.)

SIR,—I shall feel obliged if you can find room for the insertion of the enclosed report upon the cultivation of Indian wheat at Brisbane, Queensland. Dr. Bancroft wishes to ascertain the latitude and altitude at which the different kinds of wheat mentioned in the report are cultivated in this country. Perhaps some of your numerous readers may be able to supply the desired information.—Yours, &c.,

W. DYMOCK.

Malabar Hill, Dec. 6

The following interesting account by Dr. Bancroft of his experiments with varieties of Indian wheat was read at the last meeting of the Council of the Acclimatisation Society:—

Having gathered some of my experimental patches of Indian wheat, I avail myself of this opportunity of relating some of the results obtained. Last year I had no Indian wheats, and sowed on the same experimental ground Adelaide and English wheats. Neither of these arrived at the stage of maturity to furnish ripe grain. A few shrivelled seeds were formed which were allowed to fall on the ground. The sowings of these wheats of last season were arranged in various ways to determine as to the source of the rust germs. Some of the wheat was even grown in soil that had been heated to redness, yet even here the plants became rusty at the same time as those sown otherwise.

In the past season I have confined my experiments mainly to sowing eight varieties of wheat from Bombay, supplied by Dr. Dymock, and three from Mr. Anthony, of Lahore.

All these, of the sowing of May 13, 1880, are now harvested, October 14. Some of them have been ripe about one month.

No. 1—*Karam bansin*—was ripe September 19; it has a short straw, smooth chaff. The grain is small and plump. A second variety, in the same seed, had reddish chaff and a larger grain.

No. 2—*Karachi pisi*—yields heavily. The grains are wide apart; chaff white, smooth, and bearded. This variety I take to be one of the best, and strongly to be recommended for sowing. It has been ripe about a fortnight.

Dr. Dymock says this makes a good flour. The grains are somewhat heavier and better develloped than the original seeds, some of which I have kept for comparison of all the varieties.

The skin of all the new wheats is a little redder than the original samples, a circumstance I cannot yet account for.

No. 3—*Kandwah*—White chaff, long awns, heads short, grain very large. Not so prolific as No. 2, Dr. Dymock says this is a first-class wheat.

No. 4—*Lashkari*—Robust-growing wheat, with velvety chaff and long awns; grain equal to the original sample, but darker.

No. 5—*Bansir.*—Recommended for macaroni making. Has black awns, and very robust growth. This is a very large wheat.

No. 6—*Pisi*—is said to give good flour and little bran. In this sowing there came up four distinct wheats, one white, awnless, and much like English wheat. The grain is small and round, more sparingly a red chaffed beardless form, with heavy fine grain. A third white-chaffed awned wheat, which when cleaned has a dark skin. The fourth is a bearded wheat with red chaff. Those apparently the best are the two first. The grains are somewhat better than the original sample.

No. 7—*Pili*—comes up under three forms, one robust, with black beards and very large grain; a second with white chaff and awns, and small grain; and a third, velvety chaff and grain of middle size.

Nos. 8, 9, and 10 were sown near a tree, and are very poor. I shall be able to report better of them in my second patch, not yet harvested.

The wheat grown in Toowoomba, brought here by Mr. Saxon, and described as of Indian origin, I find much later. A few stools of Adelaide wheat are much ranker, and far from ripe. The success attending these Indian wheats is so encouraging that it appears to me a most important question now presents itself to Brisbane agriculturists—can wheat be grown to profit in this neighborhood? So far as my observations now go, there appears to be no doubt that several Indian wheats will grow here, yielding heavy crops, ripening before the time that rust appears. These grains do not fall out when ripe, so that harvesting need not be hurried. The grains are uniformly harder than European wheats, and will suffer less from the attacks of weevils. For the making of the wheaten meal now produced by Mr. Pettigrew these wheats may be very suitable. That the Indian wheats will be quite as good for flour making as Adelaide wheat time alone will tell. That they will prove good food, and suitable for our colonists, there can be no doubt in the mind of anyone seeing the samples placed before you.

THE TIMBER TRADE; ITS EFFECTS AND THEIR REMEDY.

THE statistics of the timber trade would seem to show that a suicidal policy is being followed. Year after year the quantity of timber imported into the London market, is increasing and with this increase the prices of almost all sorts rise. Thus, we find deals from Northern Europe quoted at £18 to £19 per standard as against £14 to £16 last year; and so on with other classes of timber. Our object is not so much to draw attention to this advance in price, *per se*, as to look at the cause. The leading cause of the great advance in the value of timber is not so much the heavy demand that exists for it, as the increasing difficulty of procuring the supplies. In the early days of the American timber trade the article was cheap, because the lumbermen could procure it at their very doors almost. Now the forests are being denuded so rapidly, that in a very few years, timber promises to be almost as valuable as some of the precious metals, unless indeed some generally adopted steps are taken, not perhaps to arrest the consumption, but to renew the forests which are being so mercilessly plundered. For the first nine months of the years given, the timber imports into London alone have been:—

		Loads.	Value.
1878	...	4,089,000	£10,363,000
1879	...	3,324,000	£ 7,352,000
1880	...	4,675,000	£11,723,000

When to this is added the consumption of the other ports, it will be seen at once how enormous is the demand made on the forests of America and Northern Europe. As for India's share in providing this timber the following statement of the English imports of teak speaks volumes:—

1878	...	...	...	...	11,900	Loads.
1879	...	...	...	...	8,200	,,
1880	...	...	...	...	3,400	,,

The reason of this declension is not a weaker demand, but an insufficient supply. British Burmah is almost denuded of this valuable tree, and supplies are now coming from native Burmah, and are intermittent, hence the advance in price, which rose from £8-10 to £10-10 in 1879, to £13-10 to £14-10 in 1880. What little timber remains in British Burmah is reported to be small in size. The teak forests are now, too, strictly preserved by the Forest Department. As soon as political changes lead to the opening up of independent Burmah, the price of teak will fall, and the customary work of denudation will go on, till a time come, when the supplies shall again become scarce. And all this time what, we would ask, is being done to replace the valuable forests. Absolutely nothing. We forget the maxim of the laird of Dumbiedykes, "Aye be sticken' in a tree, it will grow when ye're sleeping." The forests of the world, occupying tracts not likely to be used for agricultural purposes, are ample to meet the market demand for timber; but if this is to continue, they must be renewed. Apart from the commercial view of the case, there is the more important consideration as to the manner in which forests affect rainfall. On this there may be a difference of opinion, but only on details; the general principle is acquiesced in by all, that a reduction of forest land means a denudation of the soil, and thereafter a fitful and deficient rainfall. This, again, means distress and famine. It is easy to renew the forests, if the work be gone about in the proper way. An expensive and scientific Forest Department will never effect it alone, unless some wide and general scheme be devised, whereby the great bulk of the people can be interested in the movement. In India the authorities of some districts in the Punjab have gone the right way about this, and will not fail to be successful. They offer a small sum to the villagers for every tree planted and tended for four years, it being rightly considered that by that time, the young tree will be quite able to do without any special care, the shoots being beyond the reach of wandering cattle. Every villager therefore, who produces a healthy four year old tree, receives his reward. The trouble to him is almost *nil* and the guerdon tangible. If this practice were generally followed all over India, a vast improvement would be observable in the climate 10 or 15 years hence. There are immense tracts of land in India, chiefly of a hilly and stony character, which are admirably adapted for forest growth and which at one time were probably covered with forests. Those should all be planted out with suitable young saplings. The money thus spent would come back to Government with heavy interest in after years. A block of forest is needed in the neighbourhood of each village. From this the labouring man could draw his supplies of firewood, which

after a very few years, he could do without injuring the forest in any way. The manure, now used in the form of *oopla*, would thus be set free for its more legitimate uses and in every way, we should benefit by the change. This system of village forests need not interfere with agricultural operations, as there are usually large portions of land, such as gullies and gravelly land, which are not well adapted for cereal crops.—*Indian Daily News.*

TEA AND COFFEE STATISTICS.

THE official statement of the *Moral and Material Progress and Condition of India* during 1877-78, contains the following as to tea and coffee :—No statistics for the whole of India have been received of the tea cultivation in 1877-78. It was estimated that the total area under tea in Assam, Bengal, the North-Western Provinces, Punjab, Madras, and British Burmah, was 145,000 acres in 1876-77, and that the approximate yield was 29,500,000lbs. During 1876-77 the quantity exported from British India was 27,784,124lbs., valued at £2,607,425. In 1877-78 the quantity exported rose to 33,459,075lbs., and the value to £3,044,571. As regards the quality of the tea produced, there was a decided falling off, and the prices realised in London were less than they had ever been. The increase in quantity was mainly due to the circumstance that three years previously there was a great extension of cultivation, and the plants were coming in 1877-78 into full bearing, and greatly increasing the supply. Owing to high prices in former years, a tendency was developed in the manufacturer to sacrifice quality for quantity. This in the face of the large competing crop from China depressed the value and the general result was that, although the export of tea showed an increase in quantity, the pecuniary result was not so satisfactory as in previous years. Almost all the tea from Bengal goes to the United Kingdom, the exports elsewhere being trivial in comparison. Tea in Bengal is cultivated to a greater or less extent in the Cooch Behar, Dacca, Chittagong, and Chota Nagpore divisions. In 1877-78 there were in the entire province of Bengal 2,211 tea gardens, situated in altitudes varying from 13,000 to 5,000 feet above the level of the sea, covering an area of about 63,000 acres, and producing about 6,000,000lbs. of tea. Great difficulty continued to be felt in Assam in getting information from the planters as to the state of tea culture in the province. Altogether 1,718 estates, with a total area of 736,082 acres were held for the purpose of tea cultivation under different kinds of tenures, but only about a seventh of the entire area was actually planted. The total outturn of tea during the year was returned at 23,352,298lbs. Owing to the widest divergence of opinion in the matter among the planters, it was found impossible to give figures showing the cost of cultivation and manufacture. Prices received for tea during the year were generally low, owing to the London market having been flooded with coarse tea during previous years. Machinery of all kinds was being introduced into all the large gardens in the province. Further extension of tea cultivation in the Punjab was made during 1877-78 the area planted increasing from 8,060 acres to 10,046 acres, while the yield of tea rose from 761,561lbs. to 1,118,106lbs. The average yield of all the land planted was calculated at 111lbs. an acre. There is one small tea estate in the Akyab district of Arakan in British Burmah, and, when the sources of that district are better known, tea planting will doubtless, be extensively introduced. The area under cultivation during 1877-78 was 150 acres, on 120 acres of which there were mature plants. The yield for the year was 25,000lbs. of tea, mature plants producing about 209lbs. an acre. Wild tea plants are found in parts of the Tenasserim division where there is little doubt the cultivation of the plant would succeed well. A little tea is grown in some of the coffee estates in Coorg. The extent of land under cultivation of tea in the Madras Presidency was 3,112 acres in 1876-77. In 1877-78 the season was favourable for the cultivation of the plant throughout the Neilgherry district, and the exports consequently increased by about 36,000lbs. in quantity and £2 6·0 in value over those of the preceding year.

INLAND EMIGRATION.

THE report on Inland Emigration in Bengal for the year 1879-80 is full of encouragement to the large class interested in the tea industry, for it tells us in unmistakable terms that the labour difficulty is in a fair way to be surmounted. The present low range of prices of tea may be considered as but a temporary difficulty ; and although the prices obtained ten years ago may never again be the rule, the present abnormally low scale will not old good much longer. The depression is the result of certain causes—among them of over-production—and the losses at present being sustained by tea proprietors will go far to remove that cause, as under the influence of negative profits and positive losses, extensions are all but at an end for the time. At home, on the other hand, the consumption of Indian teas is slowly but steadily increasing, and now markets are being found for the produce as well. The labour difficulty is, however, a chronic one, and has pressed very hard on the planter for many years. At no time, perhaps, has the pressure been so much felt as at present, and hence we hail symptoms of its approaching termination. An artificial supply of labour is at all times an unsatisfactory one, and in this instance it was hedged around with so many legislative enactments as to make it a severe burden to the employer of labour. The new route to Assam by the Northern Bengal Railway to Kaunia, leaving only a short break to Dhubri, at once opens up a means whereby the coolie can, if he choses, find his way to Assam without the intervention of any Government or *quasi*-Government official. And the emigration returns, coupled with the records of registration at Dhubri, tell us that the coolies are taking advantage of this route in ever-increasing numbers. It must, however, be borne in mind that Dhubri is only the gateway of Assam, and having reached that station, these emigrants have still a long journey before them ere they reach the gardens higher up the valley. The distance to Debrooghur being about 4 0 miles, doubtless we shall soon have a light railway to remedy this ; but in the meantime, and in spite of this physical difficulty, 26 per cent. of the coolies imported during 1878-79 found their way on foot by Dhubri and in 1879-80, 37 per cent. At present there is a serious drawback to the success of this scheme, and it is the heavy mortality which this route seems to entail.

The following statement will show this at a glance :—

Percentage of mortality, 1879-80.

Contractors' coolies	·62
Sirdaree coolies	1·81
Non-depôt coolies	4·69
Dhubri coolies	4·67

This is the percentage of deaths during the journey up. The deaths on the Dhubri route amounted in 1878-79, to 7·96 per cent., so that matters may be mending, although it must be borne in mind that the year under notice was an unexceptionally healthy one. The causes of this heavy mortality is doubtless the extreme poverty of the immigrants, and the absence of sleeping accommodation *en route*.

Exclusive of the number registered by the Dhubri route, the total number of immigrants was as follows—two years' statistics are given for purposes of comparison :—

	1878-79.	1879-80.	Decrease. Coolies.	per cent.
Depôt coolies ...	13,795	7,601	6,194	45
Sirdaree coolies ...	11,917	4,625	7,292	61
Non-depôt coolies ...	2,439	1,224	1,115	46
Total	28,151	13,550	14,601	52

Two causes operated to bring about this decrease : they were—the depression in the tea industry, and the contended and comparatively comfortable condition of the people in those districts whence labour is usually drawn. Sundry complaints having been made as to the low type of coolies now being forwarded, the Lieutenant-Governor disclaims all responsibility as he truly points out the medical officers who examine the coolies do so with a view to see "that the emigrants are in a fit state to travel without immediate dangers to themselves, and without being a source of danger to the public, to their fellow-voyagers or to the populations among whom they are about to sojourn." He affirms that the responsibility for this should rest on the agents or employers of labour. An experiment is being made of "transferring the provisioning of the coolies to the Steamer Companies, who will also provide for their medical care and treatment." This ought to work well, and the result will be watched for with interest. The reduction in the number of coolies being forwarded by contractors has led to the number of contractors falling rom 20 to 10 four of whom are special agents on behalf of particular firms, leaving six general public contractors. During the year several stringent measures of reform were introduced into the administration of the depôts in Calcutta, with the result that the mortality in the depôts which, in 1878-79, was 2·27, fell in 1879-80 to ·46 per cent. The deaths among coolies, while on the steamers on the Assam route, were as follows—

	Coolies carried.	Deaths, per cent.
1876-77	14,646	1·46
1877-78	17,366	2·96
1878-79	16,495	3·78
1879-80	6,333	1·05

showing an improvement, which, however, may be partially due to the absence of crowding, a very much smaller number having been carried than formerly. The number of trips made with coolies was 70, giving an average of 90 per trip, where as, under the influence of a heavy traffic, those vessels must occasionally have carried far higher numbers.

LEPIDOPTERA.

WE have received the following paper on silk producing and other *lepidoptera*, by Alfred Wailly (Membre-Laureat de la Societed, *Acclimatation* de France), 110, Clapham-road, London, S. W. England.—

During several years, I have studied and reared many species of silk-producing Bombyces and other *lepidoptera*. My reports on this subject have appeared in various numbers of the "Bulletin de la Sociétéd, Acclimatation," Paris ; the "Journal of the Society of Arts," and "The Entomologist," London ; "Isis," Berlin ; "The Scientific American," New York, &c.

The sending of living cocoons and pupæ (which I purchase every year) has always been successful when they came from North America, but as it has not been so with respect to living cocoons sent from India and South America, I shall make a few remarks on the sending of live cocoons and pupæ from India, and other distant countries to Europe. The time of

sending these live insects should be, from about the beginning of October till about the beginning of April, so that the cocoons should not be subjected to the heat during the whole time of the voyage to Europe.

On the cases containing the pupæ and cocoons, there should be written in large letters; *Living pupæ or cocoons of silkworms*, and request to keep them in the coolest place inside the ship.

The cocoons should be well packed in straw, hay, moss, or anything that will deaden the shocks to which the cases may be subjected. Bare pupæ of *lepidoptera* must be placed in bran, saw-dust of fine moss. All should be sent, as soon as possible, after their formation.

Small quantities of cocoons and pupæ, should be sent by sample post, in registered boxes, not exceeding 8 ounces in weight, each; the boxes must be strong, and it is best to tie a label to each box and affix the stamps to the label.

Persons living too far inland to send living pupæ, may send dead specimens of the prefect insects: butterflies and moths. These should be in good condition and placed with folded wings in paper envelopes. As it is well known, butterflies are caught with a net; and they should be killed immediately they are captured, which can be done by carefully pinching the thorax of the insect when its wings are folded. But moths, having large bodies, would be injured if treated in this manner; they are killed by being put into a bottle containing some cyanide of potassium, or some other poison.

It is also important when the insects in papers have been placed in a box, to add some poison, to protect the specimens from the attacks of mites "Dermestes" beetles or other paracites, also from ants, &c.

As there are a great many entomologists who make a special study of the larvæ of *lepidoptera*, I shall now pass to this subject.

The rear *lepidoptera* from the egg, the moths should be placed in cages having muslin sides, for copulation and the laying of eggs. Moisture should be maintained in the cages.

A few day after the eggs have been obtained, they should be placed under glass, with a small branch or leaves of the proper food plants, so that the larvæ should have their food ready, as soon as they are hatched.

When the larvæ are small, I rear them under bellglasses, having a few holes on the dome.

These glasses, some of which are about a foot high and even larger, rest on saucers full of sand, covered with paper. Small branches of the proper food plants are plunged through the paper, into the sand and keep fresh, even without requiring water, for several days. Larvæ of some species can be reared in this manner, till they turn into pupa state. With respect to the larvæ of several species of the larger Bombycidæ, after the first or second moult, when they have ceased to wander, it is best to rear them without the glass covering. Large branches, 1 or 2 yards long, plunged in water, are then used; small twigs must be avoided, as the foliage would become too watery and cause the death of the larvæ. The larvæ should be reared in the open, but sufficiently protected, or in a well-ventilated room. Larvæ reared in the open air on the living trees, which is the best plan, should be protected from birds and other enemies. Larvæ which go in the ground to turn into pupa state, must be bred in cages having a few inches of light soil, and this plan must be adopted when the habit of the larvæ is not known.

Larvæ can be found in almost unlimited numbers on trees, shrubs, bushes, and low plants, by beating the branches or sweeping on the low plants. Larvæ which feed by night and hide themselves in the day-time, can only be obtained in large numbers, by looking for them at night with a lantern.

With regard to the sending of pupæ, and even ova of *lepidoptera*, I can say that, with a little care, and especially if those were given in charge of the captain or some other person on board ship, they could be sent to Europe from distant countries, and arrive alive and in good condition. In proof of this I can mention the fact, that in 1864, salmon and trout ova packed in a box, which was placed in the ice-house of the vessel "The Norfolk," were sent from England to Australia and Tasmania, with the most satisfactory results.

In the same manner silkworm ova, live cocoons and pupæ, could safely be sent to Europe from very distant countries, and this would be of the greatest value and interest to entomologists, for the study of living *lepidoptera* in all their various states.

THE YEAST PLANT.

THE following on the yeast plant is extracted from an article in the *Brewer's Guardian* dealing with the growth and manufacture of yeast:—

The British yeast trade, which it is anticipated will be so materially promoted by the removal of the malt-tax, constitutes to the ordinary mind one of those recondite and mysterious subjects which it requires some special mental qualifications to be able successfully to grapple with. It takes more than one generation for any new idea to work its way into the popular understanding, and it is now only about a single generation since Cagniard de la Tour discovered the yeast plant. Says the *Globe*, more correctly he has been described as re-discovering the yeast plant, since it is, we believe, undisputed that Lieuwenhoek was the first to draw attention to it in 1680, but since his day the fact of the yeast being really a plant had grown dim and dubious. Philosophers attributed the action of it to chemical changes only, and one of them at least thought he saw good reason for ascribing animal characteristics to this mysterious object. About forty years ago, however, Cagniard entered upon a series of very close and careful observations, which placed it beyond doubt that yeast was a vegetable growth. He found that it consisted of an agglomeration of minute oval cells, the diameter of which he reckoned to be about one two thousand five-hundreth part of an inch, and they propagated, he found, by a process of budding.

The yeast plant is now universally admitted to be a fungus growing and feeding on decaying organic matter, and is met with all over the globe. Nature seems, indeed, to have very carefully provided for its universal diffusion. The mildew which forms on the surface of yeast is really the fruit, the spores of which, it has been calculated, are but one-sixth of the diameter of the pollen-dust of the fir tree, showers of which have been sometimes met with hundreds of miles out at sea. When the yeast plant comes to maturity, therefore, and throws off its spores, they are very likely to travel over a great part of the earth's surface before settling. The propagation of the plant by the budding process just alluded to is very curious. A single cell will put forth one, or sometimes two tiny projections, which presently become complete cells, capable themselves of multiplying in the same manner, and thus in a few hours, under favourable circumstances a portion of yeast introduced into a saccharine fluid will increase its volume to five or six times its original dimensions. Scientific men have made a distinction between surface yeast and sediment yeast—surface yeast being, they tell us, propagated by buds, and sediment yeast by spores. Beer yeast, at any rate, has been thus divided. There is, however, very little, if any, difference in the cells of the two kinds, and sedimentary yeast appears to be only a fungus developed at a lower temperature than surface yeast, into which, as a matter of fact, it is readily converted by a rise of temperature. The reason of one kind appearing as a sediment and the other a surface growth is said to be attributable to a difference in the evolution of carbonic acid gas, the rapid generation of which keeps one "variety" of yeast at the surface, while the want of the buoyancy imparted by this generation of gas is the cause of the other kind remaining as a sediment. It seems, in fact, to be not a difference of kind, but of condition.

SUGAR CULTIVATION IN JAPAN.

IT is interesting to note the steady development of non-indigenous productions in this Empire and especially that of sugar, the consumption of which article has so greatly increased in this country of recent years.

Up to the time of the opening of Japan to foreign intercourse, the cultivation of sugar was confined chiefly to the province of Satsuma and its dependency of Loochoo, and to the southern parts of the island of Sikoku, but it is noticeable that the first step taken by the Japanese in introducing foreign inventions and systems, was in the direction of improving the sugar industry, and was undertaken by that most conservative of the feudal clans—Satsuma, who introduced into their territory in the Loochoo islands extensive sugar mills from Europe at a cost of some quarter of a million of dollars. This fact we may observe in passing has its bearing on the vexed Loochoo question, and has apparently been overlooked by the Chinese Government.

The sugar establishment in the Loochoos did not succeed, principally through neglect of using proper fertilizing agencies in the cultivation of the cane, and it was abandoned far too hastily by the Satsuma officials as they mistakenly attributed the failure to climatic causes. Whereas it has now been ascertained that among many unsurpassed advantages this country enjoys in climate, soil and products, it enjoys this important one, viz., that sugar-cane grows successfully here in a considerably higher latitude than any place yet known. Whether this is due to the beneficent action of the Kurosiwo, or Black stream, or to whatever cause, it is established that the cane will grow to perfection as far north as the province of Nambu, if not higher, and that in Yesso the Beet-root will grow in perfection, whereas in France it is confined principally to the southern part.

In China, sugar does not grow successfully further north than the Che-kiang (Ningpo) province, if we except a particular fine kind of Sorghium which grows on the large alluvial islands at the entrance of the Yangtze-kiang river. Japan, therefore, possesses an industy of great importance which can be developed to any extent, and this has been recognized fully by the late Minister of Finance, Mr. Okuma, and the present Minister of the Interior, Mr. Matsugata, to whose indefatigable exertions the success this industry promises to attain is mainly due. When it is considered that the import of sugar into Japan doubles itself every three years, and that last year four times the quantity of sugar was imported to find a profitable market than was imported twelve years before, and that the ratio of increase has been as stated we cannot deny that it is high time to extend this industry, and there is nothing apparently to prevent Japan becoming self-supporting in this import, if not of producing a sufficiency of the product for a considerable export trade.

The chain of islands of which Japan and the Philipines form a portion, promise to be one of the chief sources of supply in this part of the world. The great colonies in Australia draw their supplies chiefly from the Philippines and Mauritius, and there is no reason in the future why they should not import from Japan.

Before concluding our remarks there is another consideration with regard to sugar which in these days of Trade and Guild combinations ought not be lost sight of. Sugar is a luxury to the poorer classes, and has been found to be the first luxury they can conveniently dispense with on economical grounds. This fact was clearly established by the experience of the cotton-spinners of Lancashire during the lamentable civil war in America. The poorer classes in this Empire have little enough

saccharine matter in their customary food to exist upon, but they also have scant enough clothing to cover them, and we are much mistaken if sugar is not found to be the first luxury the people willdeny themselves if poverty extends.—*Japan Mail.*

THE ADULTERATION OF JAPAN TEAS.

DR. ALBERT. R. LEEDS, of New Jersey, writing upon the subject of the adulteration of the Japan tea, which finds its way to America, says :—

"In the examination of teas attention was directed to the determination of the percentages of ash and of tannin ; to the analysis of the ash for the discovery of foreign mineral substances, and to the examination of the structural characters of the leaves under the microscope, in order to detect the presence of other plants.

"An analysis by Mulder of black and green teas gives for the percentage of ash in the former 5·24 per cent., in the latter, 5 56 per cent., his determinations of tannin give for black tea 14 28 per cent., for green tea 17 80. While the analysis of various kinds of tea representing tea grown on various soils, in different seasons, and collected at different ages of the plant, afford other percentages for the ash and tannin, yet it is safe to say that any wide discrepancy from the above results would indicate either that we were dealing with teas containing foreign mineral substances, or with teas largely admixed with the leaves of other plants.

"A sample of what was sold as medium Japan tea yielded, according to one analysis, 6·6 per cent. of ash. A publicate specimen of the same gave 7·0 per cent. of ash. This high result pointed to the probable presence of foreign mineral matter. Under the microscope many leaves other than those of the tea-plant were found.

"Mixed tea sold at the price of thirty cents. per pound, yielded 6·5 per cent. of ash, and contained 7·9 per cent. of tannin. It was free from foreign mineral matters, but had abundance of other leaves.

"'Mixed tea sold at twenty-five cents. per pound, yielded 6·9 per cent. of ash, and contained 8·2 per cent. of tannin.

"Examinations were made of a number of low priced teas in a similar manner. After soaking, the leaves were mounted on glass slides, and compared with the microscope, both with the leaves of what was sold by the most reputable grocers of New York, at the highest prices, for genuine tea, and with the microscopic enlargements of the genuine leaves of the tea plant, figured in Hassall's standard work on the Adulteration of Food.' In the lowest priced teas it was difficult to find, in this manner, any genuine leaves whatsoever. The low percentage of tannin found in such samples likewise indicates the probable presence of a large proportion of foreign leaves.

"It is stated that plumbago, indigo, Prussian blue, clay, soap-stone, gypsum, &c., are employed either in the facing of tea or to give weight. The small percentage of iron found in the ash of the teas examined would appear to show that if the Prussian blue were employed at all in facing them, the amount must have been insignificant. The other mineral matters enumerated in the list given above we did not succeed in finding. Sufficient evidence, however, was afforded by the microscopic and chemical examination to show that while the adulterants of tea are mainly harmless they are added to such a degree as to make it one of the most adulterated articles of food.

EXPERIMENTS WITH *SORGHUM.*

THE Collector of Coimbatore has reported to the Board of Revenue on the experiment made with *Sorghum Saccharatum* during the year 1879-80. Seed was distributed to division officers, Tahsildars, and Ryots. The experiments reported are thirteen in number, the quantity of seed used in them being 60¾lbs. Of the experiments, six were in the Jungle Conservancy gardens at Coimbatore, one was in the Municipal garden at Coimbatore, one was in the jungle Conservancy garden at Udamal-pet. one was in the Sub-Collector's garden at Erode, and four were conducted by ordinary agriculturists in different villages. The results are given in the following table, from which it will be seen that the outturn varied from 868 to the enormous figure of 25,836 per cent. The least quantity sown per acre was 2 lbs., the highest 24. Except in one case where it was sown in drills, the seed was sown broad-cast ; information as to the weight and nature of the manure used in each case is imperfect. The experiments permit of the following deductions ;—

(1) *Sorghum* grows best in alluvial tank bed soil ; 25,836 per cent. was the outturn on the sowing.

(2) The next best soil for it is the best red, which gave a return of 16,800 per cent.

(3) The third best is an "ash-colored" soil, which is an ordinary or inferior black improved by ash manure ; it gave a return of 10,368 per cent.

(4) The outturn is on the whole better under rain with occasional irrigation than under irrigation with occasional rain. A fall of 4 inches distributed over some twenty days during the three months intervening between sowing and reaping is sufficient, with a few occasional waterings from a well, to secure a full crop.

(5) It can be grown either in the cold season between November and February or in the early summer between March and June ; the latter season seems on the whole the best.

(6) No useful result is gained by sowing *more* than 10lb to the acre, and this quantity seems on the whole to be about the best average for seed.

(7) The experiments do not give sufficient information upon which deductions can be made as to the nature and quantity of manure which should be applied to the various soils.

On the general question as to whether "*Sorghum*" is to take a place among the ordinary agricultural products of this district, the Collector remarks that it is objected to by the people more on account of its novelty than for any other reason that he can ascertain ; it is alleged, too, that after hulling the Salaga of 72 Madras measures produces only 3½ measures of grain, while ordinary cholum produces about 55. Some of the grain grown in the Jungle Conservancy gardens at Coimbatore was sold for Rs. 1⅝ a Salaga of 72 Madras measures, the price of ordinary cholum being above Rs. 4 a Salaga, more could not be got for it. It is proposed to continue the experiments during the coming season, and steps will be taken to make the results more indicative than those hitherto made.

NEW BRANCH OF INDUSTRY.

KURRACHEE is to be congratulated upon the establishment of another branch of industry in her midst. The Date Coffee Company of London have taken premises here and erected extensive machinery for the manufacture of coffee from dates. We have heard of wooden hams and wooden nutmegs, syrup obtained from old rags, and even of coffee made from wood, but we were not aware that this necessary article of food could be manufactured from dates. Yet such is the fact, and excellent coffee it indubitably is too. By a reference to the beforementioned wooden articles of diet we by no means wish to convey the impression that the coffee prepared by this Company in any way resembles the shams got up by our American friends or any other Yankee notions whatever. The quality of the coffee and its splendid flavour we can vouch for, having personally tried it ;—it is real *pucca* coffee and no mistake about it. Mr. Eardley Mare, the Company's representative here, hopes to have his works &c., completed and his machinery in full swing in a short time. This gentleman very kindly permitted us to inspect the premises and machinery, and also took considerable trouble in explaining to us the the *modus operandi.* The process is remarkably simple, and consists of roasting the date in shallow iron trays to a certain extent and at a certain temperature ; then the trays are withdrawn from the ovens, the dates permitted to cool and then are passed through a mill driven by steam power and thus reduced to a coarsish powder. We defy any mortal man who has never heard of or seen the process to distinguish this coffee, either by sight, smell or taste from the finest Mocha Coffee, and we are inclined to endorse the opinion of Mr. Mare that the date coffee is destined to supersede to a very large extent all other coffees in the market. Mr. Mare has only been two months amongst us, and every grain of coffee he can produce is already be spoken for the home market, and the first consignment has been shipped by the *Canara.* Date coffee is intended as a mixture in the place of Chicory so largely used in French Coffee. The Company mix with their product 25 per cent of Mocha coffee than the present mixture of Chicory ; moreover, date coffee so manufactured does not possess the heating properties of ordinary coffee, and besides contains an immense amount of nutriment. Ordinary coffee, say Mocha or Ceylon, is sold in England at 1-6d. to 1-8d. per pound ; the Company's coffee will be sold at something like half the cost, and it possesses the advantage of producing a very fine beverage from a much smaller quantity than is ordinarily used, even when pure coffee alone is employed. The Company do not in any way desire to over-rate its merits, having satisfactorily proved these in England ; and the demand is so great that Mr. Mare fears it will take him some time to meet the demands of the market.—*Beacon.*

A NEW INSECT PEST.

FROM J. WOOD-MASON, Esq., Deputy Superintendent, Indian Museum, to the Assistant Secretary to the Government of Bengal, Financial Department,—No. 36, dated Calcutta, the 25th November 1880.

I have the honour to acknowledge receipt of your letter No. 254, dated 13th, but only received by me on the 18th November, forwarding a copy of a letter from the Magistrate of Monghyr, to the Commissioner of Circuit, Bhagulpore, and a small bottle containing the dried, shrivelled, and mutilated remains of some specimens of an insect that had been attacking and seriously injuring the *dhan* in the Khurruckpore thanna, and asking for my opinion thereon.

2. In reply, I beg to inform you that I have carefully examined these specimens, and I find that they consist of *pupæ, pupal skins*, and an *adult female* of a species of *Cesidomyia*, a genus of dipterious insects which includes amongst its members at least three species destructive to cereals—the famous 'Hessian-fly' (*Cecidomyia destructor,*) whose ravages were at one time so extensive that the cultivation of wheat had to be abandoned in many parts of the United States where it had established itself, and the only less formidable 'wheat flies' (*Cecidomyia tritici et aurantica*), only too well known on account of their depredations both in America and in Europe.

3. The occurrence in India of an insect-pest belonging to the genus *Cecidomyia* has, so far as I have hitherto been able to discover, never been placed on record ; indeed, only a single species belonging to the family *Cecidomyidae*, or gall flies, has been described from India, and only two or three, the Indian one included, from all Asia.

4. The adult or perfect winged insects are only indirectly injurious to vegetation by depositing thereon their eggs ; from these, grubs are hatched in due course which suck the nutritive juices from the plants and thereby cause the inanition of the fruit. In the case of the Hessian-fly the eggs are deposited upon the tender leaves of the young wheat

plant, and the grubs, when hatched, pass down the culms or stalks as these get mature and unfit for food, eventually taking up a position between them and the vaginæ (the expanded and sheathing leaf-stocks of the leaves), and there changing to pupæ and perfect insects. In the two species of 'wheat fly,' the eggs are laid in or upon the flowers of the wheat, in which the grubs are hatched and remain until, their feeding days are over, they are ready to assume the quiescent pupal state, when they quit the plants and pass into the earth; there to undergo their metamorphoses. In the newly-discovered India pest, on the contrary, not eggs, but living grubs, all ready for their destructive work, are thrown in force into (probably) the developing panicle or 'ear,' of the rice-plant, *Cecidomyia Oryzae* or the 'Rice-fly,' as I propose provisionally to call the species, being, in fact, viviparous instead of oviparous, as in all the other known species; the agamic reproduction of *Miastor* in the larval state forming only an apparent exception to this.

5. Affecting as it does the very staff of life of the people, *Cecidomyia Oryzae* may prove a most formidable pest, and a most careful watch should be set upon its movements.

6. I beg leave to suggest that the district officers be directed to inquire, while the circumstances are all fresh in the memories of the people, and while the injured *dhan* is still uncut, what part of the rice-plant is affected, what particular variety of the rice-plant has suffered from the attacks of the pest, and what varieties, if any, seem to have enjoyed an immunity from attack.

7. In conclusion, I may say that I have already prepared some drawings, and that I shall hereafter submit as full and detailed an account of the insect as it is possible to draw up from the exceedingly meagre and ill-preserved material that has been placed at my disposal, together with such remarks as to remedial measures, &c., as the study of the rather voluminous literature of *Cecidomyian* pests may suggest. In the meantime, this brief statement of the nature of the new enemy may, I hope, prove acceptable to the Lieutenant-Governor.

From Colman Macaulay, Esq., Offg. Secretary to the Government of Bengal, Financial Department, to the Deputy Superintendent, Indian Museum, Calcutta,—No 238, dated Calcutta, the 29th November 1880.

In acknowledging the receipt of your letter No 36, dated the 25th instant, I am directed to convey the thanks of the Lieutenant-Governor for your interesting report on the insect that has lately been injuring the rice-crop in the Khurruckpore thanna of the district of Monghyr.

2. The Lieutenant-Governor will await the further detailed report on the subject promised by you. Meanwhile, the Commissioner of Bhagulpore has been asked to institute the inquiries indicated in the penultimate paragraph of your letter, and to report the result to Government on an early date. The other Commissioners of Divisions have also been asked to state if any thing has been heard of the pest in any of the districts under their charge.

WEEPING TREES.

We have no great liking for the general class of weeping trees. They are often to our mind very questionable ornaments. They are at least curious or peculiar in style, and are adapted to peculiar situations and associations. They are, for instance, admirably fitted to adorn churchyards or cemeteries, and also for planting in an isolated manner on lawns or in the foreground of ornamental plantations, by way of contrast to the more erect and natural forms of which such plantations are usually composed. They are essentially intended to be planted in an isolated manner; their form and peculiar features can only be fitly displayed in such a position as will enable them to be viewed all round. There is a very considerable number of weeping trees now in cultivation; but many are very little to be desired except by those who are curious about these peculiar examples of the freaks of Nature. The most common are the weeping-willow, in two forms, known as the American and the Kilmarnock. Of those two forms perhaps the most distinct is the Kilmarnock variety, with fine large wrinkled leaves and close habit of growth and deep green tone of colour. But the American variety is certainly the most popular. These willows are not so long-lived as certain other weeping trees, as, for instance, the elm and the ash. Of both these there are several varieties, all of which are among the most handsome of these peculiar forms. The finest form of weeping ash is that called *Fraxinus lentiscifolia*; and being very rarely seen except in occasional nurseries, we can only express our surprise at the fact, for it is one of the most handsome of weeping trees. Having all the grace of the American weeping-willow, it has an entirely distinct form of foliage; and being a deep glaucous green colour, the plant is exceptionally attractive. It has the merit also of being longer lived than the willows. The weeping form of the common ash, which is that most usually seen, is also very handsome in its way; but we think both this and the common weeping-elm might be greatly beautified by being made use of for supporting and displaying he beautiful hardy celematises which are now so numerous. One or more varieties of these planted at the roots of a well-developed ash or elm, and well attended to with water, would quickly climb the stem of the tree and overspread and intertwine among its branches over head, producing the most beautiful effect when in flower, and at no time an ill effect. Climbing roses of the most robust and hardy types could be utilized and displayed in the same way. The only difficulty in the way is the trouble that would be caused in the establishing of the plants. Any one who cannot devote special pains and attention to the establishing of them, should make no attempt to realise such a thing as we hint at. Both the ash and the elm are notoriously difficult plants to establish anything else near. They are rapacious in their demands on the soil for a long way around the spot on which they stand, and many an excellent cottage garden is ruined by the rapacity of the roots, and by the shade of both these trees. Yet with care and special means, the object we hint at above is perfectly practicable. The first thing to do would be the preparation of a pit at the base of the weeping tree as large as is possible consistent with safety to the tree. This pit must be filled with a rich compost of a lasting kind chiefly of loam. In this compost the clematis or rose should be planted, and only strong plants should be selected for the purpose. The clematis or rose must be trained up the stem with care as the growth extends; and as from its position it is likely to get but a very stinted allowance of water, care must be taken to keep it well supplied with it, and manure water should be frequently given also.

One of the most beautiful of the weeping-elms is that known as elegantissima, a small-leaved variegated sort of great beauty and moderate growth. Besides these there are weeping forms of birch and beech, the former always elegant and beautiful, but by no means often seen, while the latter must be pronounced a somewhat stiff subject. One form of the weeping-birch deserves very special mention on account of its very distinct character. It is the poplar-leaved birch, Betula populifolia). The leaves are larger than those of the common birch, and are deeper green.

ORANGE CULTIVATION IN FLORIDA.

Mr. Consul Cridland, in his report to the Foreign Office on the trade of Pensacola and some of the internal resources of the State of Florida for last year, says that formerly in Florida, as in most of the cotton States, the whole time and attention of the people was engrossed in the cultivation of the cotton plant and the sugarcane. Fruit growing was looked upon rather with contempt, and no value was attached to the wild orange groves in the State, any more than to the same quantity of other timbered lands. In fact, very frequently the wild orange trees were cut down and destroyed to make room for cotton and sugar. Of late years, however, the people of the district named have found out the importance and profits of tropical fruit culture, and the old wild orange trees are highly prized, and are converted into sweet oranges by grafting. The difficulty in regard to orange culture is the impatience for immediate results. The orange, if cultivated from the seed, requires from seven to ten years of attention before it begins to bear; and the lack of patience and confidence deters people from starting an orange grove and persisting in its care. The quality of the Florida orange, and the excellent condition in which it reaches the Northern markets, renders it a most profitable crop. There can be no fear of an over-production of the orange or lemon, when it is considered what a vast country has to be supplied. In 1879, 4,000,000 dollars' worth of oranges and lemons were imported into the United States, and the orange crop of Florida was valued at over 1,000,000 dols. From information lately published, it is probable that the orange crop in Florida this season will be 100,000,000 of oranges, for which the dealers will give the growers 1,500,000 dols. The orange crop will double itself every three or four years; and, considering that the reports to the Governor show that there are over 20,000,000 of trees in the orange groves of Florida, in future years the crop will be enormous and exceedingly profitable, and, if the 20 per cent. *ad valorem* duty continues, will stop the importation of oranges from Sicily, Spain, and the West Indies.

AGRICULTURE IN GREAT BRITAIN.

The Agricultural returns for Great Britain for 1880 have been published and furnish much interesting information, as showing how our mother country stands as an agricultural producer. It may be said that agriculture during the past year has been stationary in Great Britain. The total amount of land in Great Britain, in 1880, returned as under all kinds of crops, bare fallow, and grass was 32,102,000 acres; in Ireland 15,358,000 acres; and in the Isle of Man and Channel Islands, respectively, 97,000, and 30,000 acres. The actual increase in land under cultivation is hard to arrive at from the returns, as their increasing accuracy, year by year shows a greater increase than actually occurs. In 1880, the total area under wheat in Great Britain was 2,909,000 acres, or 19,000 acres, more than last year—the lowest on record—though this year's crop was growing on 591,000 acres less than in 1870. The land under barley beans, peas, shows a diminished acreage this year, while that under oats presents an increase of 5 per cent. over last year, the total acreage now being 2,797,000 acres In green crops, potatoes were planted on 551,000 acres, an increase of 10,000 acres on last year, and nearly equal to the figures of ten years ago. Turnips and swedes show a slight falling off from last year; wangolds a decrease of 6 per cent, cabbage, khol rabi, &c., of 4 per cent.; and vetches lucerne, and other green crops of more than 15 per cent; the present year's figures for crops of these descriptions being less than any year since 1868. The land under flax is less than half what it was ten years ago. Bare fallow, owing probably to the large number of unlet farms, has increased in the present year from 721,000 in 1879 to 812,000 acres; permanent pasture and meadow lands have increased by 260,000 acres since last year, and now amount to 14,427,000, or about 45 per cent. of the cultivated area of Great Britain. That we are giving up corn producing is apparent by the fact that, since 1870 the increase in permanent grass lands has been no less than 2½ million acres. This is what might be expected in a densely populated country, with numerous large towns, which render the feeding of cattle and the supplying of milk, butter, cheese, &c., more profitable than the growing of wheat, which is every year imported in increasing quantities from new countries, such as America and some of our Australasian Colonies. We also find another increase that we might expect, namely, in market gardens. The proportionate acreage of the large and small holdings in Great Britain has undergone little change since 1875, when the last return of them was issued,

and are now as follows :—For Great Britain, the area held in occupations of 50 acres and under, is 15 per cent. of the total; that between 50 and 100 acres, also 15 per cent.; between 100 and 300, 42 per cent.; from 300 to 500, 16 per cent; from 500 to 1,000, 10 per cent., and in farms over 1000 acres, 2 per cent. In England there is a tendency to larger occupations, the small farms of 50 acres and under being now 14 instead of 15 per cent. of the whole acreage, and those between 50 and 300 acres 54 per cent., against 56 per cent. in 1875; while farms over 301 acres amount to 32 per cent., as compared with 29 per cent. in 1875. In Scotland, occupations between 51 and 300 acres are now 59 per cent., against 58 per cent. in 1875; and the moderate-sized farms in Wales have also somewhat increased. Turning to the number of live stock there is again little variation, to notice. Medium-sized holdings (50-300 acres) still have 58 per cent. of the cattle and 50 per cent. of the sheep of Great Britain, and the number of sheep in the small holdings is now 17 per cent., as compared with 18 per cent. in 1875; cattle on the same holdings being still 24 per cent., or nearly a quarter of the whole number.

The agricultural returns give us also some information as to the live stock of Great Britain. We notice that the import of foreign horses is largely falling of, the figures being 26,000 for 1878, 15,000 for 1879, and only 6,600 for the first eight months of the current year. Of horses and cattle, Great Britain has this year 5,912,000, as against 5,856,000 last year; but sheep, through disease, have decreased by nearly a million, and lambs by half a million, the stock now being only 26,619,000. Pigs have also decreased by 91,000 in the past year, and by 483,000 since 1878. American bacon making pig-keeping not so paying an occupation as formerly, and the necessary sanitary regulations as to their being kept in large towns also operating against their increase. In Ireland we find the total cultivated area is this year 15,852,000 acres, as against 15,336,000 last year, and 15,345,000 in 1878. In 1870, the corn crops of Ireland, covered 2,173,000 acres, while now they only occupy 17,666,000 acres. The area under potatoes this year is 22,000 acres less than it was last year and 223,000 acres less than in 1878, a gloomy enough outlook truly, as regards horses and cattle in Ireland, the numbers are pretty much what they were ten years ago, but sheep, which decreased in the year half a million, now only number three and a half million; and pigs, also, which, in conjunction with potatoes, we have always regarded as synonomous with prosperity, have decreased 20 per cent. in the past year, and now number only 849,000 as against 1,072,000 last year, and 1,459,000 in 1870. Turning from these somewhat gloomy home statistics, we find appended a few particulars from the Colonies and the United States. In Australasia there are now 2,750,000 acres of land under wheat, or two and a half times the acreage under this cultivation ten years ago, and within 300,600 acres of the wheat acreage of the United Kingdom; so are our colonies growing. In live stock in Australasia, we have, it is computed, 1,050,000 horses, 7,510,000 horned cattle, 65,400,000 sheep, 810,000, pigs; while the United States possess 11,000,000 horses, 1,750,000 mules, 33,000,000 cattle, 40,500,000 sheep, and 33,500,000 pigs—goodly numbers indeed, and which make our old world figures look small and puny, and which shew us the extraordinary vitality of the new countries,—all, be it noticed, at some time, if not now. English colonies, are peopled by an English-speaking race. The old country, if as some would have us believe, now past the prime of life and in the sear and yellow, has still good cause to be proud of her children even if they have been somewhat unruly.

A NEW METHOD OF WHEAT GROWING.

MAJOR HALLETT, in the current number of the *Nineteenth Century* contributes a startling article under the head of "Our New Wheat-fields at Home." He accepts it as proved that at the present time, and for some years to come, "the cost at which an acre of wheat can be put on ship-board at a port nearer to Liverpool than New York is, will, with freight added, be so low that, under the present system of cultivation in this country (England), it could not profitably be grown here." Major Hallett's article is so thoroughly assured, so confident in tone as to be almost dictatorial; but the remedy he proposes for the British wheat-producer is simple enough, and if as we have no reason to doubt, his data are sound, a new and prosperous era should be opening to the British farmer. The remedy proposed is this: we must produce a greater weight of wheat off a given amount of ground; and the method by which we are to obtain such a desirable result is by "tillering,"—a term which we will endeavour presently to explain. It is a remarkable fact, proved by experiment, that the "number of ears of wheat produced per acre is, in the absence of injurious circumstances, virtually the same," whether the seed be sown profusely or sparsely and in this connexion Major Hallett goes on to remark that at present proper attention is not given to the time at which wheat is sown; the farmer not being so particular as to the season at which he lays this seed in the ground as he is with others, such as turnips, maugolds. &c.; that in fact, the wheat seed is sown when it is convenient, and that the crop thereby suffers to an appreciable extent. We now come to the question of "tillering." An ordinary bushel of wheat contains some 700,000 grains, and a crop of 40 bushels to the acre contains, therefore 28 millions grains per acre, and as Major Halletes tables give him, for this sized crop, 1,306,800 ears per acre, it follows that such ears contain 22 grains each. So much for the present method of planting. "Tillering" is thus described.

"A plant, of wheat consists of three principal parts, *viz.*, the roots, the stems, and the ears. The seed-grain having been planted in a proper manner, these are produced thus; shortly after the plant appears above ground it commences to put forth new and distinct stems, upon the first appearance of each of which a corresponding root bud is developed for its support; and while the new stems grow out flat over the surface of the soil, their respective roots are correspondingly developed beneath it. A plant of wheat has been known in this way to cover in May a circle 5 feet 6 inches in diameter, measured from the extremities of the opposite leaves as they lay out flat upon the ground.

"This mode of growth is called 'tillering,' and will continue until the season arrives for the stems to assume an upright growth, when tillering ceases and the whole vital power of the plant is concentrated upon the development of the ears. These will be the finest the plant is capable of producing, unless the growth of its roots has been in any way impeded, as, for instance, by those of adjoining plants, when the size and development of the ears will be found to be proportionately diminished.

"At the Exeter meeting of the British Association for the Advancement of Science of 1869, there were exhibited three plants of wheat, barley, and oats, each from a single grain, with 94, 110, and 87 ears respectively; and even these examples do not represent the *maxima* obtainable."

Now it is proved that a crop of wheat planted on Major Hallett's plan in single grains, 9 inches apart every way, produces as many *ears* per acre as does a crop sown in the ordinary method, and the advantage of the former over the latter method is that, when the plant is allowed to "tiller" an ear contains on the average 50 grains against 22 when planted in the ordinary method; *ergo*, by following Major Hallett's plan we double our crop, or, as he puts it, provide, "New Wheat Fields at Home." The paper is interesting as showing the influence of science on agriculture, and leads us to recognise the great and important fact that, if we see a supply of a commodity failing or likely to fail, we must invoke the aid of science to enable us to either increase that supply by employing new methods or by economising our use of the commodity by new inventions.

AGRICULTURAL EXPERIMENTS NEAR POONA.

(*To the Editor of the Times of India.*)

SIR,—As the *kharif* crop in a large portion of this presidency, particularly in the neighbourhood of Poona, was a source of great anxiety to the agricultural population this last monsoon, I think that an account of what I personally experienced in the *rôle* of an agriculturist may not be without interest to some of your readers. I cultivated in my own and a friend's compounds some small plots of dry crop land with the view of providing fodder for my animals of kinds. My friend's ground, some three acres in extent, I laid down in kulti, having previously dressed it with some ordinary village manure, principally ashes and stable manure. This crop proved a complete failure, the pulse only attaining the height of a few inches, so when the heavy rain fell at the beginning of October I ploughed the ground up and laid it down jowari as a *rabi* crop. At present this looks well and I am sanguine of the result. With my own land I managed better. One plot about half an acre in extent, was given up to transplanted "Teosinte," (Reana, *Euchlæna luxurians*). As my soil is very deep and black, it requires to be well aired during the time that it is idle, so in the previous December I had ploughed it up and cleaned it thoroughly. At the first appearance of rain in June I put some Reana seed into a bed of moderately manured black earth, and had it hand watered morning and evening. In four days it sprouted well. Towards the end of that month I got some cartloads of Poudrette from the Poona Municipality's works and spread a thin layer of it over the whole of the plot, working it in well with the ordinary two bullock hoe. By the time the ground was ready the Reana had sprung up nearly a foot high, so taking advantage of a cloudy drizzling day, I set men women and children to work, and in about ten hours got it all transplanted at equal distances of 18 inches every way. For the first ten days of July we had more or less light rain, and the young plants got well established. On the 27th July I hand-weeded the ground; in spite of the scarcity of rain during the previous fortnight the crop had continued to grow very fast, but August and the greater part of September proving very dry it had not made much upward growth; still each plant had thrown out many shoots, I counted in some places as many as twenty stalks coming from one seed, and the ground was so well covered with green that I had no more bother with weeds. Towards the middle of September I began to cut it for the cows, directing the gardener to only take off the shoots which were over three feet high, and not to take more than two or three from each stool. He took between 50 and 100lbs. per diem, but hardly made any impression on the field. In the beginning of October we had some heavy showers, as I have mentioned above, and then the Rena grew away from us altogether, and rapidly began to flower while the lower leaves became brown and dry. At first while the stalk was quite soft, cattle, horses, sheep ate every particle up greedily, but as the plant grew stronger, and the cuticle of the stem became harder, they became dainty, and every morning found many pieces of bare stalk left in the mangers, cut up though it was into short lengths. After a little time I noticed that all the brown dry leaves were also rejected, and very often the flower too, From this it seems that although Reana does certainly grow luxuriantly in rainy weather in dry crop soil, and much more so I have observed in irrigated land, yet it will only be of use ordinarily speaking for a short time, thus

is as long as it remains tender It is also evident that in well manured land, when once established, it resists drought successfully, making slow but steady growth.

I also tried the effect of some Reana seed in another plot of ground manured and otherwise prepared as the one I have just written about. Unfortunately I was not able to carry this into effect before the 14th July, and then the rain had well nigh ceased to fall. The seeds sprouted true enough, but only grew a few inches high, and I quite thought that the crop was gone, but, in October when the rain reached it, it took a wonderful start, growing to the height of three or four feet, throwing out many shoots and came into flower almost as soon as the first batch. Having some of the Reana corn over, I put it into a seed bed on the 16th July and watered it twice a day, as I had done with the first mentioned lot, intending to transplant it on the first good fall of rain, but for 2½ months that opportunity never came; when it did, it was too late. The plants were put out at the beginning of October, miserable, lanky, sickly things, over two feet high. In a few days they recovered themselves and began to look more promising and of a healthier colour, but this appearance was delusive, for in a short time it began to flower, and my three batches of Reana, each raised under different conditions, and varying in height from eight feet and more in the first plot to three or four in the last, were all in flower at the same time, he latter half of October. I wonder whether this is the regular time for Reana to seed in the Deccan. At present I have left off using this fodder, not being in Poona, but the gardener has been ordered to cut and dry some with the immature seed in it and gather the seed of the remainder, drying the stalks as is usually done with jowari karbe, and I shall be able to prove by and by whether the cattle will eat it in that state. It may be that when they can't get green food they will be less dainty. It is always desirable, especially in matters agricultural, to have two strings to one's bow, so on the same day on which I sowed the Reana, in my second plot of ground I got some jowari from the ryot who had just put in his seed in the adjoining field and drilled it into the lower part of my own field, so I had the opportunity of watching the effect of the season on three crops—(1) Reana, (2) Jowari both sown in black soil manured with Poudrette, and (3) Jowari sown in black soil entirely guiltless of manure. None of these crops were ever irrigated or hand watered at any time. The Jowari (2) came up in four days. Jowari (3) and Reana kept alive during the drought and eventually recovered fairly. Jowari (2) came up well and continued to grow steadily but slowly, keeping a good healthy dark green all the time; but as the drought continued I saw my neighbour's crop jowari (3) becoming yellower and yellower, and at last when the October rain fell it was too far gone to recover thoroughly and its outturn in corn and in straw was very poor. My jowari (2) has turned out a bumper in both these respects, also coming into ear very soon. From this experiment my impression is that jowari in well manured dry crop land, especially in a dry season, is more profitable than Reana as it resists drought as well, if not better, and gives good grain and good fodder. At the same time Reana, irrigated or unirrigated, yields for a short time a most valuable fodder, especially so for milch kine. How long this period can be extended remains to be proved. Next monsoon I hope to repeat these experiments, and see whether I remain of the same opinion—how many ryots can afford or obtain expensive manure, and how many can afford to plough up a failing crop and put in another?—Yours truly,

J. COUSSMAKER, Major,
Revenue Survey.

The Districts, Nov 20.

MEDICINAL PLANTS IN AFGHANISTAN.

IN the Hariab district large quantities of gum exude from the stems of the apricot tree, which is collected and eaten.

The berries of *Ribes orientale*, the fruit of *Rhamnus dahuricus*, the roots of *Daphne oleoides*, when boiled, and the dried root of *Euphorbia* sp. are all employed as purgatives, being more or less common household remedies. The last goes by the name of vomit-weed, and is also used for that purpose. The fresh milk from its leaves blisters the hand when collecting it.

For local applications the castor-oil plant is cultivated in the gardens at Kurrum for the sake of its leaves, which are employed in poultices. The roots of two species of *Arnebia*, *viz*, *A. endochroma* and *A. speciosa*, are used to relieve toothache and earache. The gum-resin which exudes from the flowering stems of *Ferula Jaeschkiana* is applied to wounds and bruises. At Alektrel a native brought me the stems of a plant, which he said was a rare and valuable medicine called "Mam-i-ran." On examination it proved to belong to some species of geranium, probably *G. Wallichianum* This no doubt, is a local substitute for the true Mam-i-ran, *viz.*, the root of *Coptis Teeta*, Wall.

The rootstocks of *Valeriana Wallichii* are collected and sent to Gundamak for export to India, to be used as a perfume.

The juice of the leaves of *Delphinium Bromonianum* is employed to destroy ticks in animals, but chiefly when they affect sheep.

The ashes obtained by burning branches of *Ephedra* are mixed with tobacco for the purpose of chewing, or with snuff to intensify its action, and the dried and powdered leaves of *Rhododendron Collettianum* as snuff.

The following plants are known to be poisonous to the natives, *viz.*, *Datura*, *Hyoscyamus*, *Cannabis*, *Atropa lutescens*, and *Solanum Dulcamara*, and, as already mentioned, one of the three weeds found amongst wheat, *viz.*, rye, wild oats or *Lolium*, *Cannabis sativa*, is known by the natives to yield an intoxicating drug, though not employed by them.

The plants poisonous to animals are:—*Stipa sibirica*, a very common grass under the shade of trees and in their vicinity near Shalizan and similar localities; its poisonous qualities are recognised by the cattle of the country which never touch it: *Rhododendron Afghanicum* is poisonous to goats and sheep.

As far as my observations have gone no oil-seeds are cultivated, nor is any oil extracted from the kernels of the apricot or walnut. The only substance in the country which the natives call oil is a crude tar obtained by distillation from the roots of a conifer. Splinters from the green wood of *Pinus excelsa*, or portions from the roots of *P. Gerardiana*, are employed in place of lights, the pieces of the roots going by the name of *Chiragh*; meaning "lamp." In lieu of vegetable oils for food the melted fat of the large-tailed sheep is used.

The tears of resin exuding from the bark of *Pinus excelsa* and the leaves of *P. Gerardiana* are collected and used for various purposes.

The large roots of *Saponaria Griffithii* are collected and employed as soap for washing purposes, and are called Zaunah. It is one of the few herbs that grow under pine trees.

The *Isatis tinctoria* (is largely used as a local dye; its native name means the dye plant at the Mussulman festival of the Id, at which hard boiled eggs are indispensable, the roots of *Runbia Kotschyi*, Boiss, are employed to give them a bright red colour.

Prunus amygdalus, Baill, is said to be quite common by the natives, and well known to them; called by the same native name as the cultivated almond *badam*. The fruit is not eaten. The stems are employed as rods to carry in the hand by the priests, but are not used as we do walking sticks; they are considered more or less holy. In orchards a tree or two of the almond may exist, but I never saw it, nor is it cultivated to my knowledge in the Kurrum Valley.

The potato was not cultivated in the Kurrum Valley previous to 1879. It has been grown during the past year.—*Chemist and Druggist.*

CURIOSITIES OF BOTANICAL ENTERPRISE.

IT is a recognised fact that no country in the world has an institution of at once as national, scientific, medicinal, commercial, agricultural, and horticultural a nature as are our famous Kew Gardens. In its herbarium may be seen the dried and beautifully prepared leaf of almost every known plant. Not hidden away in closed cases, but displayed and fully explained to the sight-seeing public of the world. Every plant that is known too to have useful application, is grown for the purpose of distribution throughout India and the Colonies; but a vast establishment such as this is, can be supported by the Government, and directed successfully by the best scientists and botanists of the age. Every planter turns to Kew directly or indirectly for help and instruction, and may feel sure that his modest request to be enlightened upon the ravages of a caterpillar, will receive as much attention and consideration as will the queries of a learned Director of one of our large Colonial gardens. Kew has done much to dissipate error, and has done her best to spread botanical knowledge, has distributed plants with lavish generosity, has sent traveller commissioners to the four corners of the earth, to the plains of the tropics, or the coldest zone of vegetation for some tiny flower or leaf that is, perhaps, a missing link in the chain of knowledge; but even Kew's great establishment is not omnipotent, and the world is a very difficult one to convince even though the great power chemistry has lately permanently engaged agriculture as her satellite. It is curious to say how often the light of science has been darkened by local obstruction or indifference. At St. Helena it is a fact that cinchona will not die; struggling against neglect and through tangled undergrowth, it had proclaimed itself as one of the hardiest trees, yet these rock scorpions prefer their New Zeland flax, and their cinchona is unnoticed and uncared for. In Trinidad, too, where this cultivation promised well, according to the report of Mr. Thyselton Dyer "nothing has been heard of cinchona lately, and the report is that it will not grow in Trinidad," this is hardly likely in the face of Mr. Morris' hopeful prophecies regarding its cultivation in Jamaica. In Java, too, a curious mistake is their determination to introduce a worthless species known as *pahadiana* which has done inestimable harm to this country's reputation as a cinchona grower. Looking nearer home, we might now wonder, why our own planters so largely planted *Succirubra*, when *Condaminea* and *Pubescens* were only to be known, to be found hardier, bigger, and of richer quality.

The great tea industry in India almost died at its commencement in the fierce controversy as to whether indigenous or China variety should be grown, and after years of fruitless dicussion, the mistake was perfected, and China tea was introduced to the great deterioration of the soft and delicate indigenous leaf. Another curious instance of conservatism that carries a lesson with it, is the determined way in which our planters of old, set their faces against any new cultivation, and swore by coffee *Arabica*, although every now and again a scientific croak from the learned one at Peradeniya warned them 'not to be greedy.' Why was not cinchona introduced years ago, and indeed why was not cacoa generally extended, when some fifteen years ago it was a visible success under the patriarch Tytler? How is it that the kernel palm and Liberian coffee were allowed to be monopolised by the negroes of the West Coast? The palms are especially remunerative and thrive luxuriantly in our low

country soil, while Liberian coffee has long ceased to be an experiment. Then regarding manufactures, how is that our Ceylon teas have been sent home so badly made that the teas, undoubtedly of fine flavour, have steadily been selling from 6*d.* to 8*d.* a lb., when it should be worth double the price of its interior China rival, and why was cinchona bark so improperly cured in the first shipments, that no London buyer would look at it; and last not least, why did we all so blindly believe that Mr. Morris had in a few months, effectually discovered the cause, life, result, and cure for leaf disease, and thus bring down bitter disappointment upon our devoted heads. All over the world mistakes mostly unavoidable, but sometimes wilful have been made in agriculture; some times brought about by following the tinkle of the bell that was on the wrong track. Well at last we have the grim consolation, *experientia docet*, and we have Kew to fall back upon; where we may learn the smallest details of cultivation, and the grandest facts of plant life. If under these circumstances the British botanical enterprise does not advance, it can only be that the British Empire itself refuses to.

ROYAL BOTANIC GARDENS, CEYLON.

THE following is the report of the Director of the Royal Botanic Gardens of Peradeniya, Hakgala, and Henaratgoda, for 1879:—

The buildings of the establishment are in very fair condition; some repairs of an unimportant character only being necessary as regards the Herbarium building and some of the smaller offices.

The road, which was under repair, as mentioned in my last annual report has been completed with the exception of some beating which will be desirable when labour can be spared for the purpose. The remainder of the roads and the walks in the garden are in good available order.

The alteration which I requested might be made in the piping bringing the supply of water into the garden, has recently been carried out, and thus a considerable area or ground can now be irrigated and made available for the construction of a scientifically arranged botanical garden, as well as for experimental purposes. It will now be possible to keep the small lake in the garden always full of water for the cultivation of interesting acquatic plants.

This department has been furnished by the Surveyor-General during the year with plans of this garden, as well as of the Hakgala and Henaratgoda gardens.

The Hakgala Superintendent reports to me that a little more work is still required for putting the arrangements for the water-supply at Hakgala into thoroughly good order.

COFFEE.—In my letters to this Government on the subject of the coffee-leaf disease since my last report, I have given my latest views on the subject and as these letters were published as Sessional Papers and have also appeared in the local newspapers, it will not be necessary for me to refer further to the subject.

Through the kind exertions of his Excellency the Governor, a considerable supply of seed coffee from the West Indies has been furnished to this establishment. These seeds have in nearly every case germinated most freely, and have produced nice healthy-looking young plants which will soon be ready for planting out. Up to the present time there has been but a very slight appearance of the leaf-disease, and it is to be hoped that this dreadful pest will not show itself to any serious extent upon this newly introduced coffee.

Liberian Coffee.—This coffee is now being very extensively cultivated in the hotter districts of Ceylon, and although it suffers to some extent from the attacks of the leaf-disease, it is hoped that this handsome species of coffee will prove a profitable investment.

Cinchona.—This cultivation has made immense progress on the hills during the last few years, and it would appear to be in many cases highly remunerative.

It will be remembered how large was the distribution of *cinchona succirubra* and of *C. officinalis* during the past few years, and how considerable the amount realised for the Government from the sales at the Hakgala garden. This selling of the plants and seeds of these two above-named species being found to be very remunerative, and the demands continuing, the planters themselves have directed their attention to supplying these demands from their own estates. It has therefore been considered most desirable that the Superintendent of the Hakgala garden should be instructed to direct his efforts particularly to the cultivation of the much esteemed *cinchona calisaya* and *C. ledgeriana* for future distribution of seeds and plants of these valuable kinds. It is interesting to know that *C. ledgeriana* grows tolerably fairly at the elevation of Peradeniya, though there is little doubt that its profitable cultivation would require a somewhat greater altitude.

Tea.—The tea enterprise continues to increase largely. Supplies of seeds for distribution are still being kept up at Peradenyia and at Hakgala to meet any demands for them which may arise.

Chocolate.—The cultivation, now a favourite one is becoming very widely spread throughout the hotter parts of the island, and bids fair to become a very profitable speculation. There is a large demand for seeds for sowing, and this demand is partly supplied from the Peradenya and Henaratgoda botanical gardens. Some enterprising planters are making arrangements for importing some of the most esteemed varieties of cacao plants from the West Indies.

Rubber-plants.—Besides sending small supplies to British India, a moderate distribution of what could be spared of *Hevea Brasiliensis* and *Manihot-glaziovii*, has been made to some planters in this island who were desirous of trying the different kinds of rubber plants on their estates. The *Manihot Glaziovii* continues to furnish ripe seeds in considerable abundance from the trees here, but although the *Hevea* and *Castilloa* plants are growing most vigorously here and at Henaratgoda, they shew no signs yet of flowering.

Mahogany.—A very considerable supply of seeds of this valuable tree has been received during the year from Jamaica. These seeds arrived in excellent condition for germinating, and a large number of young plants raised from them are growing here, and are ready for distribution to those applying for them. To the Government Agents of those provinces suitable for the cultivation of the tree have been sent, supplies of seeds with instructions as to the best mode of raising them. Some seeds have also been forwarded to the conservators of forests and others in India and elsewhere. The few old trees which are growing in this island produce seeds very sparingly indeed, so that supplies of seed from elsewhere are very acceptable from time to time. In this garden, unfortunately, the mahogany trees are liable to the attack, periodically, of a *lepidopterous* borer which checks the growth of the young shoots and consequently of the tree itself, materially.

Ipecacuanha.—Experiments in the cultivation of this valuable medicinal plant are still being continued in the Henaratgoda garden, but it must be some time before any large produce of the drug can be gathered owing to the small size of the plant and its slow growth.

Cardamoms.—Growing rhizomas are being kept up here and at Henaratgoda for sending out to applicants; but it would seem that many of the planters have now on their own estates plants to spare for disposal.

Cinnamon.—There is still a considerable demand for fresh ripe seeds at the proper time for collecting them from the trees. It must now be well known that these seeds should be sown as soon as gathered if required for germinating.

Vanilla.—Cuttings can always be supplied to those desirous of cultivating this at times very valuable plant.

Useful and ornamental trees, and flowering shrubs and herbaceous plants have been largely distributed during the year. Vegetable and flower seeds have been kept in supply as usual for the frequent application made for them.

The preliminary list of plants, &c., growing in the garden—prepared by Mr. Morris—has been printed by the Government Printer, and a considerable number of copies distributed at a charge of 12 cents. each.

The usual interchanges of plants and seeds have been made with similar botanical establishments in other parts of the world as in previous years; and contributions have been received from the Royal Botanic Gardens of Kew, St. Petersburg, Calcutta, Java, Jamaica, Singapore, and Sydney: the Acclimatisation Society of Queensland; Dr. Kirk, Consul-General of Zanzibar; the Hon'ble Mr. Leechman, and other gentlemen residing in the island.

The expenditure during the year for the several gardens of Peradeniya, Hakgala, Henaratgoda, and the Pavilion has been Rs. 32,656 and 42 cents. The receipts for sales have been Rs. 3,825 and 38 cents.

Royal Botanic Garden, Peradeniya, 18th February 1880.

G. H. K. THWAITES, DIRECTOR.

USEFUL PLANTS OF THE YUCCA FAMILY.

YUCCA BACCATA is one of the most useful plants to the Indians of New Mexico, Arizona, and Southern California. Its fruit is eaten while fresh and in a dry state. It grows from two to eighteen feet in height, and becomes a tall tree further southward, varying in diameter from eight to twenty inches. The bodies of these plants are very fibrous. Indians and Mexicans, when in want of soap, cut the stems into slices, beat them into a pulp, and mix them with water as a substitute for soap, for which it answers well. The leaves are generally about two feet in length and very fibrous. In order to remove the bast, the leaves are first soaked in water, then pounded with a wooden mallet, at the same time occasionally plunged into water to remove the liberated epidermis. Then if not sufficiently clean and white, it is returned to the water for a time, and again put through the beating process; generally the second course is sufficient. The fibres of the leaves being strong, long, and durable, are adapted for Indian manufactures; those of Southern California make with them excellent horse blankets, while all the tribes living in the country where the plant is found, use it to make ropes, nets, hair brushes, shoes, and mattresses. The plant so fibrous and so abundant, on land utterly worthless for the growth of anything more valuable, can be had for the gathering, and seems to offer a valuable meterial for paper manufacture. Another species, *Y. brevifolia*, while not so useful for Indian purposes, also affords a good raw material for paper. Vast tracts are covered with it, which assume a forest-like appearance about the Mojave river, Southern California. The plant produces an abundance of large seeds, which contain much nutrition, they are ground fine, and either eaten raw or cooked in the form of mush by Southern Californian Indians. The leaves of Y. *Whipplei* yield a very soft white fibre, capable of being made into a good thread. Indians use this fibre to form a padding to their horse blankets; the young flowering stems while in their tender condition are either eaten raw or roasted; the seeds are ground into flour and eaten. This plant in bloom is one of the finest garden ornaments, very common over most parts of California. Finally, the leaves of *Y. angustifolia*, which is very common in Utah and Arizona, yield the finest fibre of any of the *Yuccas*, and like all of them is

adapted to manufacturing purposes. The young flowering stems are used by the Indians after the manner of asparagus, and eaten raw or cooked, are not to be despised. The root, pounded up, is employed as a substitute for soap.—*Dr. E. Palmer.*

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The usual Monthly General Meeting was held on Thursday, the 25th November 1880.

W. H. COGSWELL, Esq., V.P., *in the Chair.*

THE Proceedings of the last (September) meeting were read and confirmed.

The following were elected Members :—

The Maharajah of Churkaree, Bundelcund; the Manager of the Tarapore Tea Co., Burtall Division; and Mr. James Strachan, C.E., Kurrachee.

The names of the following were submitted for Membership :—

His Highness the Maharajah of Travancore,—proposed by the Rajah Suttyanund Ghosal, Bahadoor, seconded by Baboo Peary Chand Mittra.

M. G. Stewart, Esq., Merchant, Calcutta,—proposed by Mr. W. H. Cogswell, seconded by Mr. W. Stalkartt.

A. B. Kellie, Esq., Manager Singtom Tea Garden, Darjeeling,—proposed by Mr. W. S. Creswell, seconded by the Secretary.

C. H. Pillans, Esq., Tea Planter, Phoolbarrie, Silligoorie,—proposed by Mr. G. L. Kemp, seconded by the Secretary

Rejoined.—Dr. R. H. Perkins, Jubbulpore.

The following Gentleman was proposed, on the recommendation of the Council, as an Honorary Member :—

Captain J. F. Pogson, Simla.

CONTRIBUTIONS.

List of Articles from Bengal to the Melbourne Exhibition of 1880. From the Compiler.

A plant of *Croton Kingii.* From Mr. G. Bartlett.

Seed of *Doryanthes Palmeri.* From L. A. Bernays, Esq.

A small collection of Orchids from Sylhet. From C. K. Hudson, Esq.

GARDEN.

A report from the Garden Committee was read and agreed to. The Committee propose the erection on the west side, and contiguous to the Superintendent's house, of a substantial iron house, at a cost not exceeding one thousand rupees, for the proper display and safety of orchids, begonias, ferns, aroids, crotons of rarer kinds, &c.; and the removal of the *cutcha* shed to the south of the house, which is now appropriated principally for orchids, as it is an insecure position. "This recommendation"—the Committee observe "is quite independent of that made some time ago, for an ornamental structure in a more open part of the grounds, which they would still much wish to see carried out, if any wealthy native gentleman would give the necessary amount; the house being called after his name, as is the case in the Zoological Garden houses." The Committee next recommend some further expenditure for the purchase of certain plants of which the stock is limited, and which are generally in request. They allude to the present establishment and to the cost thereof; and introduce a few details in respect to stock, &c. They close their report with the following remarks :—

"*Manures.*—A large quantity has already been collected during the past six weeks, and further supplies are being obtained without cost to the Society, except that of cartage. The Committee propose very shortly to call Mr. Kiernander's attention to the subject-matter of their previous reports of March and April last, in connection with the Resolution of the Government of India, (Agricultural Department) under date, the 27th February 1880. The suggestions of the Committee were not carried out last rainy season, partly for want of the necessary material in shape of manures, partly to the attention of the Society having been called to the subject by the Government of Bengal, rather too late in the year, and partly to other causes."

ALOE FIBRE.

Submitted the following letter from Mr. C. S. Faddy, District Engineer, Hushiarpur, Punjab, and report on the fibre therein referred to :—

"I am sending you by to-day's post a small parcel containing

(I) Sample of Fibre.

(II) Sample of Fibre.

(III) A small length of rope. And shall feel obliged by your kindly favouring me with an opinion as to whether the fibre could obtain any value as an article of commerce in the Indian or Home markets. The plant from which this fibre is produced, grows freely all over Northern India, but no use is ever made of it by the natives. I also send a small quantity of combings suitable perhaps for tow or paper fabric."

Mr. W. H. Cogswell, a Member of the Fibre Committee, gives the following report on the above samples, Mr. S. H. Robinson, concurring :—

"With reference to the samples herewith alluded to in the foregoing memorandum, I beg to observe that the washed and heckled fibre prepared from the "Agave Americana" or common aloe is about the best I have seen being beautifully clean and well freed from the bark or outer skin of the plant, of good color, there being but a very slight tinge of greenish, which it is impossible to thoroughly eradicate without extra steeping, or the addition of chemicals, to the injury of the fibre; it is of very great length and fair strength and a really good commercial commodity, its value to-day being about eight rupees a bazaar maund."

"The sample unheckled I would value at about one rupee a maund less."

"The sample of combings, generally known as tow, could be used in this country for paper-making only, its value as such being about three rupees a maund, but in England, when spinning machinery can be applied to it, a good yarn might be produced. As a product for shipment thereto it is of greater value than being consumed locally for paper-making. For the latter, I am of opinion, it is too good and costly, a jute tow, and such like fibres, are so cheap and plentiful in this market."

ON THE INTRODUCTION OF CERTAIN FOOD GRAINS IN THE HIMALAYA.

The following extracts of a letter from Captain J. F. Pogson, dated Kotaghur, 12th November, were next submitted :—

It may interest the Agri-Horticultural Society to know, that the Moravain Missionaries at Keelong, in Lahoul, are very successfully cultivating Rye, (*Secale Corealle*) in that most out of the way portion of British territory. The Rev. Mr. Hyde, was here in October, and stated that some seed Rye, was sent him in a letter from Germany, which was sown, grown, and harvested, and by several annual resowings of the produce, this new and valuable cereal has been fully established in Lahoul, so, to these Missionaries belongs the credit of doing a most useful thing, whilst we have not got beyond the writing stage. Perhaps Himalayan Tea planters will now be induced to import seed Rye, and cultivate this cereal, next year. Mr. Hyde mentioned the Quinoa seed [*Chenopodium quinoa*] sent him by the late Sir Donald Macleod and said, that the crop was harvested at maturity. The people did not fancy it as a food grain, nor do they care much for Rye. The Quinoa he held would grow best in a tropical portion of the Himalayas, Lahool being beyond the tropics and having a spring and summer very much resembling that of Canada.

You may remember that I suggested this food grain should be tried in the high ranges of hills north of Simla, at and above elevations of eight to ten thousand feet of altitude above the sea level. Thus Mount Huttoo and the Upper parts of Narkunda would have produced good crops of Quinoa. Practically speaking the experiment was so managed as to ensure failure.

I have promised Mr. Hyde, seeds of Maize, and "Maha kuddoo" and shall be much obliged if you will in due season let me have at least 100 picked seed of the pumpkin in question. Mr. Manikin, Forest Officer and Assistant Superintendent Hill States, wishes to introduce it into Kilba, and Nachar in Kunawar, and Rev. Pagel wants it for his Mission Station in Pu, in a Thibetian Pergunnah, belonging to the State of Busahir.

On the banks of the Sutledge at Kapoo the "*Sambadai* Zemindar, was supplied by me with acclimatized American Maize seed and "Maha kuddoo." The man was so pleased with his abundant maize crop, that he has preserved all the cobs for next year's sowing, and other zemindars have done the same. Now as Cuzco maize of kinds, red included, has been successfully grown at Kapoo. I have reason to believe that the very large seeded Cuzco maize grown by Colonel Chamberlain, at Ranikhet, and myself at Simla, will answer at Kapoo; therefore, if you can secure me some of this seed I will get the zemindar to cultivate it. The *kuddoo*, also flourished, and as it would have required four Paharees, to bring the largest one up hill to Kotgurh my leave was asked, as to incurring the charge, and as paying a rupee to look at a pumpkin was not necessary, I was satisfied with the description, "length 3 feet, width 1½ cubits (27 inches) weight a load for 4 men which may be called 120 seers, or 3 maunds. From Nirit 9 miles *en route* from this to Rampore, another monster pumpkin was reported. So the valley of the Sutledge agrees with the pumpkin.

I hope those who have tried their cultivation in the plains have been as, if not more, successful.

When it comes to hand I should like to obtain one or two oz. of the so called wheat rice, or more if it can be spared, as I will send some to Lahoul, (Keelong) and Pu.

In reference to the Quinoa as mentioned by Captain Pogson, the Secretary called attention to the following particulars from the *Treasury of Botany* :—

"The species to which the greatest interest attaches is, however, C. Quinoa, indigenous to the Pacific slopes of the Andes, where it is largely cultivated in Peru and Chili for the sake of its seeds, which are extensively used as an article of food. They are prepared either by boiling in water like rice or oatmeal, a kind of gruel being the result, which is seasoned with the chili, pepper and other condiments; or the grains or slightly roasted like Coffee, boiled in water and strained, the Brown coloured broth thus prepared being seasoned as in the first process. This second preparation is called 'Carapulque,' and is said to be a favourite dish with the ladies of Simla.

However prepared, the Quinoa is unpalatable to strangers, though it is probably a nutritious article of food from the amount of albumen it contains. Two varieties are cultivated, one producing very pale seeds called the white, which is that employed as food, and a dark red fruited one called the Red-quinoa. A sweetened decoction of the seeds of the latter is used medicinally as an application to sores and bruises, and cataplasms are also made from it."

Agreed—That the major portion of the fine maize from Nepaul, recently presented by Mr. Girdlestone be forwarded to Captain Pogson for trial.

CROCODILE OIL.

The Secretary drew attention to the following extracts of letters from Messrs. J. Purcell, of Allahabad and J. M. Keane, of Agra, in reference to the letter from the Eglinton Chemical Company of Glasgow, which was read at the August Meeting :—

Mr. Purcell.—"I am in receipt of your favors, dated 13th July and 17th instant, and am sorry I have no oil (crocodile) with me that I could send you for the firm in Scotland.

"In December last I had a very large quantity of Crocodile oil at Agra. I sent a bottle full as samples to several firms when I sent you some, but have received no favourable reply, and as also that of Dr. K. L. Dey being unfavorable, I gave the oil away to the native leather curers and servants, the latter used it for months for lighting purposes, and it showed a fine clear bright light. While at Mussoorie in October or November last, I also received a pamphlet from some chemical firm either from England or Scotland I am not certain, but being about to leave for the plain I mislaid it or lost it."

"At present the river is high, but about December next, I might be able to send you some oil say a 5 gallon Kerosine oil can. Had Dr. Dey's report been favourable, I could have sent you as much oil as the firm would have required.

Mr. Keane.—"I am in receipt of your favor of the 7th instant. The Crocodile oil can only be procured in small quantities from the Sansis in the Punjab. If the Glasgow firm who wish to obtain it would pay my passage to Lahore and back, I would be happy to take a trip there and obtain as much as I could for them, but it would I think be better for them to start a factory for it somewhere here or the Punjab as they could then depend upon its purity and in conjunction with it the skins might be roughly tanned and exported to Glasgow as it makes excellent fishermen's boots, but of course it would need capital. I would be happy to undertake its management if they are inclined to speculate in it."

Resolved—That a copy of this day's proceedings be sent to the Glasgow Company for their information and for such steps as they may desire to take.

RAVAGES OF THE WHITE ANT ON TEA ESTATES.

Read a letter from Messrs. Octavius Steel & Co., intimating that the white ants are causing some of the managers of their tea estates much annoyance and even anxiety, that they have not succeeded as yet in finding any effectual means of killing them off, though they have with much perseverance tried lime, kerosine oil, charcoal, and other supposed remedies without any permanent effect; and requesting to be informed of any other suggested treatment likely to check, if not stop entirely their ravages.

The following is copy of reply to the above application :—

"The subject of the distruction caused by White Ants on living plants, and inanimate objects, has been frequently before the Society at various times, and certain remedies for their removal have been suggested, but apparently with little or no effect. I may, however, mention that many years ago these insects caused much depredation on plots of sugarcane of foreign kinds in the Society's garden. Various supposed remedies were ineffectually tried, but only one had any real effect, and that was mustard cake. This was applied in the first instance, simply as a manure for the cane; but it had quite unexpectedly the effect of introducing the red ant largely into the plantation, and these completely destroyed their white brethren; so much so indeed that we were not troubled again by the latter.

"I would recommend this being attempted in your tea gardens; besides a constant hoeing round about the roots of the plants which may assist towards the exterpation of this formidable pest."

The usual Monthly General Meeting was held on Thursday, the 16th December 1880.

W. H. COGSWELL, V. P., *in the Chair.*

THE poceedings of the last meeting were read and confirmed.

The following were elected Ordinarry Members :—

His Highness the Maharajah of Travancore, Messrs. M. G. Stewart, A. B. Kellie, and C. H. Pillans.

Honorary Member.—Captain J. F. Pogson.

CONTRIBUTIONS.

1. Report on the progress and condition of the Royal Gardens at Kew for 1879. From the Director.

2. Memoirs of the Geological Survey of India, Palæontologia Indica, Ser. XI. Parts 1 2. From the Director.

3. Transactions of the Asiatic Society of Japan, Vol. 8, Part 3. From the Society.

4. Journal of the Asiatic Society of Bengal, Part 1, No. 3. 1880. From the Society.

It is agreed, on the recommendation of the Council that orders for vegetable seeds from England and America, similar to those for 1880, be given for next year. Further, that as the flower seeds have not been favourably reported on by several Members, nor by the Garden Superintendent, that the orders be distributed to several seedsmen in England and the Continent. The season in England for 1879, was very unfavourable for the gathering of flower seeds.

It was further agreed that an exhibition of vegetables and fruits be held in the Town Hall on Thursday, the 20th of January and of flowers in the Garden on Thursday, the 3rd of February.

The Secretary reported that a large consignment of Rose plants from Mr. W. Bull, had been recently received in excellent condition, only one out of 400 plants having been found dead on opening the box.

Letters were read from the Government of the Punjab applying for a large quantity of seed of *Reana luxurians* for sowing along the banks of cannals in the Baree Doab and Western Jumna Circles and for cotton seed of the Bamieh variety.

The Secretary reported that he had been able to comply partially with the request for Reana seed, but that no cotton seed was available.

From Messrs. Peel Jacob and Co., applying on behalf of correspondent in Cochin China, for full information in respect to the culture and manufacture of Jute.

The Secretary intimated that he had been able to meet this request through the kindness of the Chairman. *Agreed*, that the valuable information now given be printed in the next number of the Journal for general information.

MINERALOGY.

THE production of petroleum last year in America exceeded that of any previous year by about 5 million barrels. Nearly twenty million barrels of the crude oil were extracted. The number of new wells drilled amounted to 3,038 about the same as in previous years; but a smaller percentage of them proved to be dry or worthless, only about six per cent. as against eleven per cent. in 1878. The exports exceeded the shipments in 1878 by nearly two and a quarter million of barrels; the stock accumulated at Pennsylvania on January 1st, 1880, was 7,404,908 barrels, being an increase in the year of 3,855,191 barrels. All this looks favorable for the continuance of low prices of the refined oil all over the world, whilst it is of course not so favorable for the prospect of the produce of the wells in Upper Burmah and those recently discovered in Arracan.

THE Directors of the Indian Phœnix Gold Mining Company notify that the explorations made on the Phœnix estate by Captain Giffard, the mining engineer of the Indian Glenrock Gold Mining Company, have resulted in a very satisfactory exhibition of gold in the reef examined, which he describes as six feet wide. The Directors have secured the services of Mr. Daniel Grove, late President to both the mining boards of Bendigo, Victoria, and the Thames Goldfields, New Zealand, who left England last week to proceed direct to the Wynaad for that purpose. We also learn from the home papers that eight bags of quartz, taken from the South-East Wynaad estates were forwarded to Messrs. Johnson, Matthey & Co., whose assay shows an average of 60 oz. 9 dwts. per ton, inclusive of the Bolingbroke leader. Further certificates from the same firm and from the Royal School of Mines give the assay of leaders on the Elizabeth estate 8 oz. per ton, and on the Needlerock estate of 60 oz. and 608 oz. per ton.

THE (London) *Statesman* writes on the subject of India gold mining:—

Mr. Brough Smyth, who has returned from India within the last month, is understood to have brought with him reports concerning the gold fields of Southern India of a somewhat sensational character. Remembering how important it is to the people of India that we should lighten the burden of our Home charges upon their industry, and that the State is the great owner of the soil, we might have hoped that the Government would long ere this have ascertained for itself beyond cavil what the true value of this ancient gold fields has become, under modern processes, for extracting the metal from the soils in which it is imbedded. Mr. Smyth's "prospecting" has been confined, we believe to the Wynaad district, an elevated plateau of land lying midway between the Neilgherry Hills and the Malabar Coast. The gold fields of Mysore are declared greatly to exceed those of the Wynaad in richness of yield, and it is in the Colar district of Mysore, we believe, that the Madras Gold Mining Company (Arbuthnot & Co.) and the Mysore Gold Company have opened their "workings." The mining rights in the whole of this Colar district have been leased with doubtful propriety, we should think, to a body of private *concessionaires*, under whose "grants" these companies are "working." A recent prospectus of the Colar Gold Mining Company tells us that "from accounts and reports submitted to the *concessionaires*, 17 tons of stone raised (on the Ooregum block) from a depth of about 18 feet, and treated (with machinery not of the best), yielded 40½ ounces of gold, and again from a different though adjacent lode 9 tons gave 27½ ounces." If these reports are reliable, and gold is really to be obtained from the quartz in these quantities by the modern processes of crushing, the value of these fields must be enormous. It is a proof, we think, of the apathy with which we administer India that the Government shows no adequate sign of being conscious of what these reports mean. If these reports are reliable, instead of conceding "mining rignts" at nominal rates to parties, the State itself should work the mines in the interest of the people, and realize its Home charges, or a part of them, if possible, in this way. The attention of the Government cannot be too soon directed to this subject. Under the ascendency of Sir Bartle Frere, the Government of Lord Canning, twenty years ago, alienated in perpetuity to a body of mere land-jobbers the finest tea lands in Assam at nominal prices, with a pledge never to impose a land-tax upon them ? The same folly will be repeated with these gold fields, apparently, from sheer want of insight into what their discovery means. The facts should be ascertained beyond dispute, and private concessions stopped instantly, if the workings are found to be as valuable as they are now declared to be as the State should work them.

THE WYNAAD GOLD FIELDS.

I HAVE inspected altogether twelve estates some very minutely, and all critically. I have not, however, visited every gold district of Wynaad, nor even all those of greatest public interest. A good deal of animus and scepticism has been shown in the criticism of the Indian gold movement. Outside Wynaad the Indian gold fields are spoken of by some as a myth and a "hum," got up for an occasion; it has been rumoured that Austra-

lian quartz has been brought into the country with intent not the most honourable; it has been confidently stated that the people in the gold district do not believe in the affair; all kinds of hostile sayings have been current about it; and high officialdom knowing nothing whatever about the matter, has consigned it to the limbo of all Indian rubbish. Those who visit Wynaad my be shown reefs of two to fourteen feet in width, having outcrops plainly indicated by large masses and boulders coursing in a line down the sides of hills. They can see fragments, and boulders of quartz of varying size and quality scattered about in all directions. They can be shown numerous specimens gathered in the country containing specks and small pieces of fine gold. They can have sands and soils washed before their own eyes and yielding weighable gold. They can see places from which specimens have been sent to analysts of reputation, and they can see the written or printed certificates, showing sometimes the modest yield of two or four pennyweights to the ton, sometimes the brilliant averages of one hundred to eight hundred ounces. As to the rumour concerning the importation of Australian quartz into Wynaad, I am at a loss to account for it. It may, indeed, have arisen from a distorted version of a trick, regarded here as a mere hoax, which was practised on Mr. Brough Smyth during his examination of the country. Some picked specimens were taken from Devala and carefully deposited on a property near Vellirimulla. That gentleman, however was not to be deceived by fictitious appearances as will be seen from his report on the matter. One thing favourable to mining in Wynaad is the conformation of the country. In most districts where reefs have been discovered the hills rise at least 250 feet above the water-levels of their adjacent valleys, and in many places near the edge of the plateau they reach as much as 1,000 and 1,500 feet. For this reason pumping—one of the most expensive items in mining—will seldom be necessary at first, and in certain cases not at all. Moreover it will seldom be necessary to sink vertical shafts for other than ventilating purposes. The expenses of hauling mineral up vertical shafts opening on hill tops, and of wheeling it along horizontal levels opening out at the hillsides often bear a proportion to each other of no less than six to one. So that the advantage of having mountainous country in which to mine is obvious. Timber and water, as I mentioned in my last letter are plentiful. The question of labour is of great importance. It is not enough to dispose of it by saying that "labour is cheap from 4 to 5 annas a day." In the first place the labour obtainable at that price is of very little value in mining; and in the second place most of the labour is fluctuating. It is not indigenous, but has to be imported from Mysore and the coast. The labours are exceedingly independent and work only when they please. They come to Wynaad when it suits them, and having collected together a few rupees, return to their own countries either to cultivate their land or spend their money in idleness. One company has disposed in a summary way of the whole labour difficulty by sending to China for 300 Chinamen. This, however, is a venture, the success of which is by no means certain. I have said, and I say it again, that there are estates in Wynaad, which so far as mere surface appearances indicate give great promise as mining properties. There are others, however, which give but little promise. Nevertheless in judging from surface indications one can never arrive at certainties; indeed, in pronouncing on reefs at all it is as well to bear in mind that there is nothing so certain of them as uncertainty. The reef which shows so well at the surface may be found on deep sinking to run out suddenly; and on the other hand, the outcrop that shows itself as a short narrow strip of quartz at the surface may widen out underground into a large and valuable reef. I was told some time ago by a mining engineer of considerable experience that he believed many of the reefs in Wynaad did not extend beyond a depth of 20 to 30 feet below the surface, and he stated it as his opinion that unless they reached a depth of 500 feet, they were not worth working. There is no doubt that many masses of quartz which crop up to the surface do terminate at the slight depth. But this is not always an unfavourable sign. Amongst the various signs and features of the occurrence in Wynaad of gold reefs, rich or poor, extensive or limited, there are undoubtedly indications, sufficient to show that it is worth risking some capital to have their character more definitely ascertained. The knowledge we possess of them at present is for the most part obtained from merely surface indications. But they are indications as good of their kind as those which have led to the opening out of other goldfields. And well-directed efforts to open out mining enterprises in Wynaad must be attended in many instances, with the best success. There will be failures as a matter of course. There have been some very worthless reports written on mining properties in Wynaad. There have been reports written on the mere strength of a morning's walk over an estate, and the sight of a few masses of quartz appearing above the surface of the ground, and containing, perhaps, a specimen showing visible gold. In one case a mining engineer reported on an estate without ever having seen it. The various gold companies are not likely to actually turn out gold for some time to come; estates have to be first carefully surveyed and thoroughly prospected, plans of working have to be fixed upon and matured, estimates prepared, buildings erected, machinery purchased in England brought carefully and slowly from the coast up to the ghât, and then erected on the estate—all before the first outturn of gold can be looked for—and this preliminary work requires twelve to eighteen months, or even two years. By careful and well considered working of this kind there is every hope that many of the mining concerns will prove steadily and even brilliantly successful, and will, in spite of the numerous failures which will result from reckless speculation, vindicate the character of the Wynaad gold fields.—*Correspondent of the Bombay Gazette.*

SOUTH WYNAAD, Nov. 23.

GOLD AND COAL IN INDIA.

BESIDES the paper on India, Diamonds which we have already noticed, another was recently read by Mr. Ball before the Royal Dublin Society, in which he described the distribution of gold in India. In this he gave a very clearly written account of explorations in the Wynaad region by Mr. W. King, of the Survey, and by Mr. Brough Smith, the details of which have from time to time appeared or been referred to in these columns. Mr. Ball is decidedly of the opinion that gold mining in the Wynaad and Mysore ought to pay well if completely managed. The paper mentions many other districts in India where gold is known to occur, and where certain castes make a precarious livelihood by washing for it in the streams. During his personal explorations in the hilly districts of South-West Bengal, he came in contact with several colonies of these people and found that through the accumulated experience of generations they had been able to mark off certain well defined geological boundaries within which gold washing paid them enough to live on, and beyond which it would not pay. This boundary he found to coincide with the line of separation between the metamorphic and sub metamorphic rocks. In the description of the gold-bearing streams of the Himalayas and Tibet, Mr. Ball mentions the explanation of Herodotus's tradition of the gold-digging ants, that was unexpectedly and unconsciously hit upon by one of the pundits sent over the Himalayas by Colonel Montgomerie, of the trigonometrical Survey. The story, which has been often repeated by veracious travellers like Sir John Maundeville, asserts that in a country north of India there are enormous ants as big as wolves which burrow in the ground and throw up sand full of gold. The Indians stealthily approach and fill this sand into bags which are laden on fleet camels and thus carried away beyond the reach of the enraged ants which sometimes sally forth and destroy the plunderers. These ants are really Tibetan miners who in the course of ages, have excavated enormous quantities of auriferous alluvial deposits, and who still probably carry on the work in much the same way as their ancestors did in the days of Herodotus. They work at an elevation of about 16,000 feet above the sea where the winter is terribly severe, yet they prefer to work in winter, because the frozen soil then stands without artificial support. To protect themselves from the fearful cold they have to clothe themselves in furs like Arctic voyagers, and they underground or pitch their tents in deep pit to protect them from the cutting wind. Hence the story of the burrowing ants. At a previous meeting of the Society, Mr. Ball read a paper on Indian coal and coal-mining showing the extent to which this industry has developed in recent years. It appears that at present about half the total coal consumed in India, is raised in the country and that when the Assam fields are opened out, this proportion will be considerably increased.—*Pioneer.*

NELLORE COPPER WORKINGS.

THE following reports of these workings by Mr. King, is taken from the memoirs of the Geological Survey of India, Volume XVI, part 2:—

The mineral or building resources of this part of the Carnatic have already been generally and incidentally noticed, from which it will have been surmised that they are not of any great value or importance, except locally, or because they have not been sufficiently developed.

However, the Nellore district is more particularly known in this connection as having from time to time given promise of good copper ores. The proper region of workings lies just on the northern edge of the present area, and was examined by Charles Æ. Oldham, or on the southern edge of the next area treated of in Mr. Foote's memoir; but I have failed to discover Oldham's notes, and Mr. Foote only refers to this mineral resource very cursorily. My own work did not lie anywhere near this region, so that I only saw the faintest traces, previously noticed, occurring on the right bank of the Penner, near Yarabully. However, I saw most of the specimens collected by Oldham, and these, with his verbal information regarding them when compared with the Yarabully rocks, all showed that the copper occurs in a band of hornblendic and garnetiferous schists, with which are associated intrusive sheets of trap. The strings and irregular masses and nests of copper ore occur for the most part in the traps, but they also run with the schists. There is no regular distribution of those in the traps, but the strings run across and occasionally with the laminæ of the schists. No good and tolerably continuous lode is apparent, nor has one ever been found: indeed, the general look of the rocks and of the country is most unpromising, there being very little signs of copper at the surface, the best specimens only being found among the *débris* from the old workings, while every hole that has been made only shows how all attempts to mine must have been rapidly frustrated by the influx of water.

Good big lumps of earthy-looking trap are often obtainable, with a good deal of ore distributed through them, which certainly have a very promising look, and this is about the most that can be said of the industry, for all attempts have hitherto failed to produce any encouraging returns; nevertheless I am not prepared to encourage the hopeless view generally taken of the evidences that have been brought to light by the old workers. In my experience of native workings, I have always found with the exception of the old gold workings in Wynaad, where the man had to deal with an undulating country easily drained, that the mines have never been carried to any depth nor to any extent, as may be easily conceived

where the means of getting rid of water, or the supplying of air were not available. I do not mean to urge the oft—in difficulty or despair—suggested necessity for going deeper in mines to obtain a better result, though of course the wealth may be at a great depth ; but I question whether any of these old native mines are ever beyond 60 feet in depth, or that the galleries run more than three times that length. Again, the fact of the place having been tried under European hands, and at a great expenditure of money without success is poor evidence of the condition of a mining region in India, for it is even now difficult to obtain competent and steady hands, or, even, if they be competent to guard them against the evil and enervating effects of the climate, and it is, above all difficult to arrange for the effective administration of such work. From all I could ever learn of the working of the Nellore mines, these obstacles to progress seem to have occurred in the most exemplary manner. The money seem to have been at hand ; but neither Colonel Ouchterlony nor his brother James, nor Messrs. Hart and Simpson seems to have been capable of carrying on or organising the administrative part of the affair, while solitude, sickness and drunkenness were too much for the miners.

The localities appear to be principally within the outlying zemindari lands of Kalahasti. Those visited by Mr. Oldham are at and in the neighbourhood of Garimanipenta (Gunnipenta) on the northern edge of the sheet and within some 24 miles of the western hills. The specimens he produced were principally copper glance in irregular masses, with strings of malachite occurring in massive earthy trap and in hornblende schists. They were all from the heaps of *débris* thrown out of the excavations which had been made near the village. The traps appear to occur as intrusive sheets running with the schists, but the ore in the latter is in nests or strings running with the foliation, and nothing is known as to the lie of the irregular masses in the traps, these all being from *débris*.

THE diamond fever at the Cape of Good Hope is likely to be revived by the discovery of an immense diamond, of which Mr. Rhodes is the lucky proprietor. The diamond was found in Griqualand West. Mr. Rhodes has refused £75,000 for a half-share in this diamond, and it is believed to be the largest diamond that has ever been found at the Cape. It is said to be of a very white and pure quality.

FORESTRY.

THE SIKKIM FORESTS.

AS seen from the left bank of the Great Rungeet the destruction of forest in Independent Sikkim is going on at an alarming rate. A few years ago the whole of the hills within sight were covered from top to bottom with magnificent virgin forest ; now the hill sides are almost bare and the denudation has gone on increasing rapidly and steadily each year. This portion of Sikkim has been colonised by immigrants from Nepaul, and every one knows what an implacable enemy to trees of any kind the Paháriah is. Indeed so great is his natural propensity in this line, that he will wantonly and in a sheer spirit of mischief cut down with his *khookery* any sapling that may be handy as he passes along a road. He certainly does not, as a rule, *jhoom* as the Lepchas do, and once he has cleared a bit of ground for cultivation, will continue to raise crops on it as long as the soil gives him any return, and he has a rude notion of cultivating the land. But at the same time he gets everything out of the soil he possibly can and very seldom puts anything into it in return. On the other hand he will burn acres of forest when he is allowed, for the sake of the undergrowth which springs up after the forest trees have been destroyed, to provide fodder for his cattle or to allow of his raising crops of rice, maize, or millet. Judging from the wanton destruction of forest in Sikkim during the last seven years or so, it is only a question of the not very remote future, before the whole of this country is utterly denuded of trees as the destruction of the forest appears to increase in geometrical progression yearly. Can Government do nothing to put a stop to this wilful waste, which in a short time must infallibly result in woeful want?—*Darjeeling News.*

THE ANCIENT FOREST WEALTH OF INDIA.

IN the course of an exceedingly interesting article on the Deccan, published in the present number of the *Fortnightly Review*, Sir David Wedderburn makes some remarks on Indian Forests which we would commend to the notice of the department.

Bijapore, whose splendid ruins deserve to be reckoned among the wonders of the world, offers the fullest evidence that, two hundred years ago, the whole country around it was well covered with trees. Yet the traveller through the vast, undulating plain, which intervenes between that famous capital and the districts bordering on Bombay discovers scarcely a trace of vegetation. Every reader of old Indian literature, of the Mahabharatha, the Ramayana, for example, cannot but perceive that the India of those days was by no means the treeless, sun-scorched land which we now know it. Sir David Wedderburn may not be aware that the forest of Dandaka, to take a single instance, must have been far more vast than the Hercynian forest, which in Roman time covered Central Europe, yet of the forest of Dandaka, little remains except a few scrubby patches on the Vindhyas. Throughout the works of the Mahomedan historians, also, are scattered many indications of the existence of extensive forest tracts of which no remnants survive in our day. The subject of the ancient forest wealth of India and in subsequent denudation is well worthy of the attention of officers like Dr. Brandis and Mr. Baden Powell. The latter named gentleman in particular would find it a theme specially adapted to his facile pen. The general causes of forest denudation are perhaps obvious enough. Conservation, managed so as not only to counteract but even more than make good the amount of consumption, is, in India at least, a modern art, and there are very few arts of English importation which are more deserving of prosecution. Municipal Funds might, with the greatest advantage, be spent in tree-planting. This would not serve for purposes of adornment—itself a great consideration amidst the general baldness and monotony—but would also prove useful as regards local sanitation. The Famine Commissioner's suggestions on afforestation as a means of regulating rainfall, and therefore the yield of crops are already acknowledged as the A. B. C. of the subject. The case of Bahawalpur—we mean the town, the Nawab's large palace, and its surroundings—offers an excellent illustration in point. Fifteen or sixteen years since, the grounds round this palace were completely devoid of vegetation. At this time, they are well-stocked with trees; and fine avenues many miles in length have sprung up in the interval, affording grateful shade, and beautifying the landscape—*Indian Herald.*

UTILITY OF TREES.

IN many instances the controversies which arise from conflicting theories are set at rest by an appeal to experience, but as according to the proverb none are so blind as those who are unwilling to see, even that is lost upon persons too obstinate to admit that they were mistaken. The utility of trees in ameliorating climates, attracting rains and preventing floods is now being generally admitted, but there are nevertheless persons still obstinate enough to deny it.

The great use of trees has made itself felt more particularly in districts where the wholesale extirpation of forests had been undertaken for obtaining timber and agricultural soil, it being wellknown for its extraordinary fertility, after being during centuries covered by layers of decaying leaves which produce the humus. As soon as the denudation from forest had been undertaken on a large scale in certain parts of North America, the climate deteriorated, and droughts never known before began to afflict them.

On hill sides trees prevent the denudation of the soil which would be washed off by torrents if it were not sheltered. The foliage of trees does not allow the rain to fall to the ground with violence, and their roots so interpenetrate it as to form a kind of net-work hindering its removal; the roots also act as conductors of water to the lower strata of the soil whence it percolates into cavities or subterranean lakes which being filled, the water again finds its way out and thus trees become the cause of springs or rivulets. Also the brushwood growing around trees acts beneficially upon the soil, which it likewise contributes to strengthen by arresting the floods which would otherwise cut it up and form ravines for rushing torrents. The destructive floods which periodically devasted the valleys of the Loire, the Rhone and the Garonne, and which had never occurred before the forests on the hills were extirpated, are now being prevented in France by the Forest Department which has undertaken the reforesting (*reboisement*) of all the mountain slopes. All who are acquainted with natural history, known that not only animate beings but also plants breathe. The process of inhalation and exhalation is peretually going on with trees; great masses of them evaporate large quantities of moisture drawn from the earth which form mists and clouds again returning to the earth in the shape of rain. Clouds passing over tall forests sometimes impinge against them and discharge a portion of their contents. Under the shade of trees the temperature is naturally always somewhat lower and the air a little more moist. Trees may be made to act as curtains against winds especially when these might be injurious to certain classes of plants. The pestiferous exhalations of the pontine marshes in the vicinity of Rome are checked by a curtain of trees, so that the agriculturists who live beyond it are not subject to the malarious fevers for which those marshes are famous.

Trees are useful also on declivities where scarcely any other cultivation can be carried on, it was however a mistake of Sir Richard Temple's government to convert all the waste land of Poona into forest preserves, but this error has now to some extent been corrected; the measure will nevertheless for some time to come be felt to be a very hard one, especially by the poor.

Not only fuel and timber will become more abundant after a few years but also the other advantages connected with forest culture, briefly alluded to above, will appear. Those who think that the measures taken by government for the purpose of reforesting the Dekkan are superfluous even if carried out with leniency, will have to live down their opposition, until another Governor comes, who may perhaps think fit to abolish them instead of only modifying them. We remember that petitions numerously signed were forwarded to Government, dwelling on the hardships that would ensue from the smoke of the railway trains passing too near the Band-stand, and against the passing of the tramway through certain localities to endanger the lives of children. Now these matters are forgotten, and nobody has any objections against the engines nor against the tram cars. When the advantages of reforesting become palpably obvious the objections against it will also fall into oblivion.

SOME RESULTS OF AFFORESTATION.

A PARAGRAPH in one of the American newspapers which we received by yesterday's mail, states that in 1841 Lord Carr planted with trees a portion of his estate in Nairnshire, Scotland, which was utterly unfitted for agricultural purposes. Lately an account was made up of the result of the experiment. It was then ascertained that no less than £16,000 clear of all expenses has already been received from sales of timber, while the land is still fully stocked with trees and annual clearings, producing a large revenue, are taking place regularly. It has also been estimated that the nett profits were as great from this formerly sterile waste, as would have been the case with the best arable land.

No better practical proof than the result of Lord Carr's experiment could, perhaps, be afforded of the splendid results obtainable from Forestation, and an example is given which should not be lost sight of here in Japan. It is a patent fact that forest trees are rapidly disappearing all over this country, consequent upon the demands to supply the requirements of railways, telegraphs, commerce, &c, &c. The resulting increase in the price of timber is now apparent, and points most unmistakeably to the not far distant period, when the warnings we have so frequently given upon this subject will be exemplified with very unpleasant distinctness.

France, it is well known to those who take an interest in Forestation, is one of the countries—if not *the* country—where the science has been practised with the most signally successful results. At the last Paris Exhibition, in order to bring the working of the department practically before visitors, the Administration des Eaux et Forets erected a Swiss chalet on the slope of the Trocadero, in which were shown illustrations of what had been doing in Forestry, and a report, arising principally out of this display has recently been issued. From this extremely interesting document, we learn that the forests of France only occupy about 17 per cent, to the total area of the country, or twenty-two and a-half million of acres, while Sweden has 43 per cent. of woodland, Russia 37, Austria 33, Germany 27, Switzerland 18, and Great Britian the insignificant quantity of 4 per cent. The forests in France are over two-thirds private property, while the Government has absolute control over only about 11 per cent.

The department has made some valuable experiments with foreign woods. The Australian blue gum prospers exceedingly in the south of France, and the marshes at the mouth of the Var have been drained, and the fever prevailing there ended by planting this species of tree. In poor soil, and as preparation for more valuable trees, the American oak has been largely made use of, and experiments are in progress with the theya tree of California, the wood of which is valuable in the manufacture of the finer descriptions of furniture.

The most important work of the department, however, has been the replanting places where forests once existed, and of the dunes or sandhills, those dreary wastes which are associated in the minds of most of us with pictures of shepherds on stilts busily engaged in knitting. It is of course, useless to attempt to plant trees upon hill-tops exposed to the full blasts of the wind, so the plan followed by the department has been to build weirs in the gorges through which mountain torrents rush in winter. These weirs retain the water, which forms ponds in summer instead of becoming dry. By the modified action of the water so dammed back, a broad, deep layer of soil is formed, upon which first grass, then bushes and ultimately trees, grow. As soon as the bushes and trees begin to grow, others soon follow, which are protected by the first. A commencement once made in this way, it is easy to change the weirs, and the original plan can be pursued and rendered more simple by the assistance afforded by the trees already growing. In course of time the mountain becomes gradually covered with wood from the gorges. the mountain stream, too, is brought under subjection, since it supplies moisture to and in turn is supplied by the growing trees. The streamlet never dries up now, as it did when the mountain was bare and its snow waters simply rushed down in the spring to leave the land arid in summer. An example of this description is given in the case of the Torrente de Bourget. As recently as in 1868 it was only a ravine of bare rocks. The hollow has since been half filled by high stone dams. The beneficial results of the work are seen in the trees and bushes which grow to the very edge of the ravine, and in the torrent being now innocuous, and never devastating the valley below with periodical inundations, as was formerly the case.

In the portion of the report which summarizes the results hitherto attained, we read that from 1861 to 1877, 68,000 acres of land were planted with trees and 3,700 additional acres turfed, the cost being about £315,000. The report states that the comparatively small amount of work done was owing largely to the fact, that the communes and private owners had paid but little attention to the subject. It is some slight satisfaction to known that the apathy in Japan is not exceptional, and we derive encouragement from the statement that interest in Forestry is rapidly growing in France, and among the very classes who formerly looked upon the operations of the department with an indifference amounting in some instances almost to contempt.

The laws in France on the subject of Forestation appear well calculated to promote the object in view. Grants of seeds, young trees, money, &c., may be made, and compulsory replanting is provided for in the extreme cases in which such a peremptory step is considered necessary. The Government can also enter upon private property to accomplish afforestation, and if the owner desires to re-occupy the property he must repay the expenses or surrender half of the land so improved.

The planting of the sand dunes which form their nature are continually shifting, is accomplished by laying them out in sections and building strong fences along the crests. Towards these divisions fences other smaller ones lead zig-zag fashion, The sand constantly accumulates in the protected places and thus forms bulwark for the space in the rear. The area so protected is then planted with meadow grass, sedges, broom or esparto grass. These when growing, are protected by brushwood and, when once the grass has gained a footing, coniferous trees are planted. In this way many thousands of acres have been reclaimed between the Gironde and the Coubre, and it seems as if the extinction of our well-remembered shepherd on stilts was only a mere question of time.

GARDEN.

SINGLE-FLOWERED DAHLIAS.

THESE are becoming yearly more popular for decorative purposes. They are superseding the old double florists varieties completely for all purposes, excepting, of course, the purpose of competition at flower shows. They are elegant in style, extremely free in flowering, and very brilliant in colouring, remarkably more so than any of florists sorts, especially in the case of scarlets and crimsons. They may also be grown in pots for conservatory decoration and for cut-flower purposes in late autumn and early winter, with complete success. For this purpose they should be grown in pots, in the same way and by the same treatment as chrysanthemums, along with which they produce a gorgeous display when in full flower, their seasons of flowering being the same when treated together. Like chrysanthemums, they should be propagated in batches at different periods, to bloom early and late; but the propagation need not commence so early for them as for the chrysanthemum, because they want a shorter season to come to the flowering stage. They should be potted about May into 9, 10, or 12 inch pots, according to the size of plant desired and the space that may be devoted to them, and plunged in the ground

or in coal ashes in the open air, and cultivated liberally. In autumn before frost is apprehended, they should be brought indoors. They are not so hardy as the chrysanthemum, and must not be exposed to the least frost, or they will be crippled more or less. A strong, rich compost should be used in potting, but let it be well mixed and the manure well matured. They may be had in flower from July to January without difficulty.

ON THE CULTURE OF TUBEROUS BEGONIAS.

THE details of the culture of this popular class of greenhouse plants should rigtly begin with their treatment when they are going to rest. The bulk of those grown for summer decoration of the greenhouse will now be going to rest and there are one or two points of management at this period which should be clearly understood and strictly observed in practice, in order to mature the tubers thoroughly so that they may not be rot during winter.

The first point to be observed is to gradually withhold water from the root as soon as the stems and leaves show signs of decay. Begonias unlike many other plants which are tuberous or bulbous, do not show these signs of decay at the upper extremities of the shoots or stems first, but at the lower extremities. Very often indeed extra vigorous plants damp or 'fog' off close to the crown of the tuber while the upper parts of the stem and branches and even the leaves show but very little symptoms of distress. But as soon as these indications of going to rest are observed, the supply of water should also be gradually reduced. The plants should also be placed in a sunny and airy position One out of doors where they may be sheltered from strong wind, will suit them better than the more confined atmosphere of a house, or frame, as the stems die off let them be cut away, but none should be cut which are not quite dead. When the stems are all cut away, the pots should be put on their sides under the stage of a cold green house where they will not be exposed to any heat above 35 to 39 degs. but where they will not be liable to any frost whatever. In this position they will be quite safe for the winter. They should never, however, be put away in a dust-dry condition. They rot or decay as readily in extreme dryness as in extreme wetness.

The time of starting the roots into growth should be regulated by circumstances. If they are simply intended for the decoration of the greenhouse during any period of the summer, they may be brought out of the dormant state by placing them in mild heat two or three months before the time they are desired to be at their best. By attending to this point and bringing them in batches of such a number as may be required for the purpose in view a very long succession of their beautiful flowers may be kept up. But if they should be wanted for the purpose, first, of yielding a number of cuttings for propagation, as in the case of scarce and desirable sorts, they must be taken into heat early in the beginning of the year.

Having determined the time the roots are to be brought into activity, let them be taken to the potting bench, and there turned out of their pots, and entirely freed from the old soil. Every root should be carefully examined in order to detect any rotten parts, which should be cleaned away; and if the rot is of a soft nature, the affected parts should be dusted with quicklime after being well cleaned. More generally, however, the rot will be found to be of a dry sort, and the affected part will break away from that which is sound, leaving a perfectly callused surface underneath, which requires no treatment. These may be potted and put in heat at once, but the others should be allowed to lie exposed to a brisk warm air or dry heat for a day or two before being potted, so that the wounds may become quite dry and the lime crusted upon them. They may then be potted and placed with the others in temperature of about 55 to 60 degs. at night, if they are to be propagated by cuttings; but if merely to be grown into decorative plants, they should be treated to 5 degs. less at night, with, in either case a rise of 5 degs. during the day. We shall now follow the course of treatment required ordinarily for the production of plants for the purpose of decoration only, and leave the treatment of those intended for the purpose of propagation, along with the details of the treatment of the cuttings, for subsequent consideration.

At the first potting the roots should be put in the smallest sized pots. Very small roots, such as may be obtained from cuttings of the previous year may be put in 2-inch or 3-inch pots, according to the size of the roots, and these smaller sized roots should be just merely covered with soil. But in the case of large sized roots, the less soil there is between them and the sides of the pot the better: nor should these be covered with soil at all, the surface of the tuber should be just level with the soil. A little water should be given, merely a sprinkling to settle the soil about the root; but with the exception of a light dewing over with the syringe in the morning, that is all the moisture they should receive till they show inctive signs of growing, after which water must be given in proportion to the progress of growth. The temperature should remain the same from first to last, except it be desired to push them faster than they may be doing for any special purpose. But they are plants that should not be pushed by heat for any considerable length of time. They delight in a light friable loam, rich in manurial matters, such as dried cow or horse dung, bone meal, and leaf mould. The proportion of these to the bulk of the soil depends upon the quality of the soil. Should it be poor, a third of leaf mould may be added, and a fourth of dried cow or horse dung, and to every bushel of this, about a quarter of a peck of bone meal may be given, and thoroughly well mixed. A little sharp sand if the soil is of a close or clayey sort, will be needful to keep all open an porous. When the stems begin to grow a pace, discontinue the use of the syringe over head, but keep the moisture of the atmosphere abundant by means of the evaporating troughs, and sprinkling the walls and passages with water several times a day. Stakes must be applied to the stems betimes, so as to prevent accidents. The plants must also receive additional pot room as soon as they appear to want it. They should not be allowed to become pot-bound in any degree till they occupy their flowering pots, after which they may be kept up by means of liquid manure.

THE JAPANESE CHRYSANTHEMUM ELAINE.

THE class of Japanese chrysanthemums, which for some time after its intro duction was very little esteemed, is rapidly growing in favour. The flowers of the new class were so little in accordance with the points set up by florists as the criterion of perfection of those of the older class, that it was not to be wondered at if they made little way in favour for some years after they were introduced. It began, however, to be observed that the Japanese kinds were extremely hardy in constitution, and very free bloomers. It was noticed also by some leading growers that, when well grown their less precisely symetrical flowers were a relief and a contrast to those of the older favourites. Their merits became gradually more conspicuous through the influence of these leading growers, and attention was given to the improvement of the flowers of the class which has proved most successful in the production of certain varieties with flowers of more symmetrical perfection than those of the eartier kinds. The most valuable that has yet appeared is the one whose name stands at the head of this note. It is pure white, the purest white of all chrysanthemums yet introduced: large in size, so much when well grown as 7 or 8 inches in diameter, but most useful for cut-flower purposes when less liberally cultivated. It is now grown by market florists by the thousand for its pure white flowers, which are in great demand for decoration of all kinds in which white flowers are essential. It is naturally a late flowering sort, but by early propagation it may be had in flower as early as any of the other large flowering kinds, and its naturally late habit may be turned to advantage in prolonging the season of flowering by propagating at later periods. It may, in fact, be had in bloom from October to February if well managed in the way indicated.

Early flowering Pompone chrysanthemums. These, as a class of this popular flower, are on the increase alike as regards favour and variety. They bloom early enough to be available for flower-garden decoration in autumn, and they may be obtained in pots in flower both early and late, by means of propagating at successive periods. They are very largely cultivated now for the supply of the London flower market and other large towns.

The following selection comprises some of the best:—

Indica Alba, a white variety, very dwarf and compact in habit, with pure white flowers when flowered under glass, but somewhat creamy in tint when flowered in the open air.

Illustration.—A taller and more erect growing sort, reaching the height of about two feet; a remarkably profuse bloomer, with pale pink flowers in the open air, which come almost pure white when flowered indoors.

Delphine de Cabache.—A bright yellow sort, very profuse and of good erect habit, about two feet high.

Precocite.—Another beautiful golden-yellow variety, most profuse and early, about two feet high; very compact and branching in habit.

Crimson Gem—One of the very earliest and one of the most profuse and compact. The flowers are small, bright bronzy-crimson, extremely well adapted for bedding out.

Bob.—Another fine crimson, of larger growth and larger flowers. The flowers are a rich deep crimson.

Helleborus altifolius, or *H. niger maximus* is one of the most valuable of hardy white winter flowers. By some it is considered a totally distinct species of Christmas rose, although many regard it as merely an improved and larger flowered sort of the older and better known species. Be its affinity what it may, there is no fair comparison between the value of the one and the other in point of usefulness for the purpose of decoration. The sort above named is by far the best, indeed it is the only Christmas rose worth growing for the purpose of cutting. Wherever large quantities of pure white cut-flowers are wanted, this should be grown in abundance. It should be grown in the open ground in rich soil in such a way as that frames may be placed over the plants when winter sets in, so that the flowers may be preserved from being tarnished by wet. It may also be potted up from the open ground and placed in the greenhouse to flower or it may be lifted from the open ground and planted in the border of a peach-house or vinery. The plant is easily increased by division, which should be done as it starts into growth during spring.

Lachenalias.—These little known bulbs from the Cape of Good Hope are deserving of more favour than, judging by the fact that they are seldom to be met with in private collections, they appear to get. They are profuse flowering, elegant things, of the easiest possible culture. They are also all but hardy, and may be grown in the open air during summer while the protection merely of a cold frame in winter is all they need if better or warmer quarters cannot be afforded to them. They are small growing bulbs, which, when well established in parts, are among the most profuse in flowering of any class of bulbs with which we are acquainted; L. tricolor, which is the best known of the group, is also the

most profuse blooming. The flowers are about an inch long, tube-shaped, and set thickly on a stout foot-stalk, the length of spike being about from two to four inches, according to the strength of the bulb. They are orange, green, and yellow, and last well when cut and are well kept in water. Their culture is a very simple matter. As to soil, sandy loam, with a liberal allowance of partially decomposed cow-dung and leaf mould, suit them well. Once potted the plants should not be disturbed for a year or two. Six inch pots are the handiest size in which to grow them. Drain the pots well, for although Lachenalias will take any quantity of water during the growing season, yet they are impatient of stagnation at the roots. Place twelve to eighteen or twenty bulbs in each pot, according to the strength of the bulbs themselves, and also according to the object in view, whether it is to establish the pots at once or to be content with thinly filled pots for a season. They may be potted at any time after flowering is over; and after potting, they should be watered sparingly till they show signs, of starting into growth. When this is observed, water more freely. After growth is finished, gradually withhold water, but do not, as is generally recommended, dry them off. They should always have as much water at their roots as will prevent them shrivelling up. They may be potted in batches with advantage from March till the middle of August; and if they are introduced into growth in the order of potting, they will maintain a very long display or an exceedingly pretty and somewhat rare flower.

TEA.

THE Pegu province (British Burmah) imported last year, 186,170lbs. of Chinese tea from the Straits, valued at Rs. 88,898 a small advance on the quantity taken the previous year, whilst the value of the importation of the larger quantity was less. This is attributed to a good crop in China having reduced prices. Some tea declared for Upper Burmah is not included in the above account. Every year there is a steady increase in the consumption of tea in Burmah by all classes, and those interested in Indian teas should surely be able to oust the inferior Chinese qualities from this market if they cared to set about it. But the Chinese importers have their agents in every village of importance in the province, collecting produce of all kinds—hides, horns, ivory, bees-wax, &c., and these men are of course most useful to their principal as pedlars or petty shopkeepers to sell the Chinese tea in the principal Burmese villages.

CEYLON TEA FOR THE AUSTRALIAN MARKET.

(To the Editor of the Ceylon Observer.)

SIR,—A great deal has been written, in the local prints, about the superior quality of the Ceylon tea as compared with that which usually comes from China, and it seems to have become an understood thing that our mission is to supply the Australian Colonies with a good article, but at a good big rate. Why people have got this notion into their heads, I cannot say as it is a notorous fact, that to Australia, as good, if not better, teas go as a rule, than those sent to England. After many years' residence in Australia, my taste for the China tea became acquired, and I have all along preferred it to that of Ceylon. For some years back, I have tried to improve (?) my taste, by drinking the teas made at Looleecondura, Rookwood, Kandaloya, Oliphant, and other estates, but, after all, I have gone back to the China tea with pleasure, and I feel sure that we must after our style of manufacturing the commodity, if we purpose securing the Australian trade. Most of the shipments to the Southern Colonies go from Foochow, and these are admitted to be about the finest grown The Australian dealers are *very quick* at detecting any attempt at adulteration, and a proof of this was given a few years ago, when some Hong-Kong shippers sent a few spurious consignment to the Australian market, and since then Hong-Kong teas have become unsaleable there. I believe that my taste for tea is similar to that of 90 per cent of the colonists in Australasia; my taste may be a vitiated one, but I have tried, for seven years to convert it to the Ceylon views, and having failed, have gone back to my old love, China tea. The Ceylon tea is too new, as a rule, when we drink it, but what it lacks, as far as my taste goes, is the "pick-me-up" which all Australians prefer to any spirits whatever, but it would take gallons of Ceylon tea to instil the same feeling into me as the pannikin of China tea used to do. I know that it is high treason to say anything in Ceylon against the products of the Island, but I am merely hinting that there is something which we might do to alter the flavour of our teas if we wish to secure the Australian trade, and that trade alone is all that Ceylon would require, as, in the Southern Colonies, the people drink as much tea as Ceylon is ever likely to produce. As things stand at present, we make tea in what we are pleased to consider a *perfect* manner, and we become indignant if any one hints at any improvement, or suggests that China tea is preferable. I think, however, that it will be found a difficult matter to educate the Australians, to our way of thinking, and I merely give myself as an example when I say, that, after trying Ceylon tea for seven years, I still prefer that from China, and have gone back to it, although it cost more than what I can buy Ceylon tea for. Let no one suppose that I am prejudiced against Ceylon tea, quite the contrary is the case; I have tried my best to take kindly to it but it does not compare, in my opinion, with the tea which I used to drink in Australia, and as long as we think we are perfect, we will never improve, and so we cannot secure the Australian trade, for I am positively sure, not from my own experience alone, but from that of many other Australians, that as long as our teas have their present *flat* flavours we can never be considered qualified to supply the Australian market. I know there are many tea planters in Ceylon who will simply say that it is my bad taste which makes me entertain these views, and that I don't know good tea when I get it. That I am quite willing to admit; at the same time I believe that the greater number of colonists in Australia will agree with what I say, and if our tea planters are so pigheaded that they won't be advised, but will persist in going on, in the belief that they will *compel* the Australians to come round to their way of thinking, I can only say they have a difficult contract to fulfil.

INDIAN TEA IN AUSTRALIA.

THE following is the report of the Syndicate appointed to represent the interests of the Indian tea trade at the Melbourne exhibition:—

Melbourne, 14th October 1880.

R. B. Magor, Esq., Honorary Secretary, Calcutta Tea Syndicate.

Dear Sir,—The sale of the first lot of the Syndicate teas took place yesterday with a very satisfactory result, thanks to the good work Messrs. Jas. Henty & Co. have done in assisting me to look up the trade here generally both wholesale and retail, and also thank to the publicity given to our project by the daily papers, of which I am sending you some copies. I telegraphed you the prices of some of the larger lots sold. Messrs. Henty & Co. are now sending you a fully priced catalogue. The afternoon teas at the exhibition did a good deal also towards helping the sale. They are a great success; so great that I have had to issue cards of invitation, as the general public are too strong for the resources of the court. The public will, have no doubt, taken our teas if the grocers will sell them at a reasonable price. A good opening has now been made, and it rests with the merchants of Calcutta to keep up a regular supply of the right qualities to make the trade with this colony a permanent and growing business. By the right qualities, I mean such teas as Lots 3, 9, 36, 41, 42, 48, 18, and 29, as detailed below, the two latter in small quantities, as there is only a limited demand for the finer grades. The prices realized for most of the teas are not extravagant which I look on as a good sign. As they will most probably go into consumption quickly and a demand will arise, I do not look for a lower range of prices, but this is a market which could very easily be swamped as there is amongst a great number of the trade a distress of the article which it is difficult to overcome. However, with a steady supply of suitable kinds and patience I have no doubt our difficulties with such people will disappear. Small well-made Pekoes, broken Pekoe Souchongs, and leaf broken Pekoe Souchongs with tips, are the most suitable sorts to send small boxes (about 10lbs., nett) and half chests (not more than 40lbs. nett) are the packages liked; the teas should be carefully bulked and weighed, but the weight not marked on the package as there is some difficulty with the Customs. I have been making inquiries about the chances of a trade with Sydney, but am not encouraged to send on a shipment there and hesitate to do so until I have been to see whether the great prejudice which I am told exists against our teas is a reality or only a fancy. I intend running over before selling off the whole of the Cingalese invoice, in case I may find a demand for it there. The Governor, Lord Loftus was over here for the opening of the Exhibition, and desired me particularly to make an effort to open up the trade in his colony. He thinks there is a splendid chance for it, but from others I have a very contrary opinion. The Thain has given us a good deal of trouble, as the Executive Commissioners would not see its beauties and relegated it to an out-of-the-way corner. However, with the assistance of Mr. Buck, the President of our Commission (who all through has helped in every way, giving me best position in the court for the tea show, and aiding me with advice) we have at last succeeded in getting it a good place in the grounds, and by the next mail I hope to send you a photograph of it. The two servants I brought down with me have turned out very well, and are quite an attraction at the afternoon teas. I am Dear Sir, Yours faithfully,) (Sd.) D. A. Sibthorp.

CEYLON TEAS IN AUSTRALIA.

AT the present times planters and merchants in Ceylon are more that ever inclined to take a practical view of everything with which they are connected, and they naturally feel far deeper interest in the industrial portion of the Melborne Exhibition and the prospects of a good outlet for their produce through its means, than in the most costly and magnificent collections of manufactures or works of art. We are to a great extent interested in the progress made by the Southern Colonies in that marvellous development of their own *resources*, which has done so much

to place them in the foremost rank of British Colonies. All this betokens a capacity for the consumption of articles in which other Colonies are interested; and it is natural that Ceylon takes a deep interest in the material welfare of the Australian people, seeing that their progress and prosperity determine their capacity as consumers of those articles which we are able to supply. The Australians are able to pour into the markets of Europe gold, copper, tin, wool, wheat, and a variety of other articles, all of the finest quality, and all finding a ready market at paying rates. Ceylon has not much need for supplies of these articles, and we shall probably look more to their wines, their horses and their provisions for an exchange for our own tea, coffee, and cocoanut oil. The enormous population of the Australian Colonies points to a large consumption of the articles we are able to produce, and which have hitherto been little known in the Southern settlements. Our coffee has indeed been shipped thither for many years past, but not to any great extent, for the good reason that the bulk of the colonists, are addicted to the use of tea, which is preferred even in the towns and which is solely used amongst the squatters and gold-diggers of the interior.

Australia is an excellent customer to the Chinese for their teas, consuming many millions of pounds in a year. A good deal of this it is true, is of the ordinary and cheap kind, but there is also a large quantity of the inferior class of the teas taken for consumption in the towns, and for these prices ranging from 1*s*. 6*d*. to 3*s*, are freely paid. When the question of tea shipments to Australia was first mooted, it was the opinion of some that Australia would only take the commoner varieties of the article at a very low figure; but this assumption was based on the supposition that our tea would only find favour amongst the labouring classes in the outlying districts working on farms or in the mining districts. The probability of good Indian and Ceylon teas coming into request amongst residence of the better class in the large towns, does not seem to have arisen. It is evident, however, from the prices quoted, that both Indian and Ceylon teas are appreciated, and are being taken into consumption at prices beyond what can be obtained in the London market. It unfortunately happens for the tea-planters of Ceylon that at the present moment the home market is glutted with cheap China rubbish teas which although not coming into competition with our own article necessarily depress the market.

We have no information as to the stocks of tea at the Australian ports; but from the accounts received of the result of recent sales shewing how readily parcels of Indian and Ceylon teas offered at auction were taken off, it would appear, that there is nothing in the state of Australian stock, to interfere with prices. The highest price realised at recent tea sales in Melbourne was, as our correspondent pointed out—2*s*. 7½*d*. per lb. for a parcel of Darjeeling Pekoe. Of the Ceylon tea the highest price realised was for some half chests of Galbodde Pekoe which brought 2*s*. ½*d*. per lb. Ten half chests of Kandaloya Pekoe realised 2*s*. ¼*d*. per lb. Galbodde broken Pekoe brought 1*s*. 9½*d*., whilst Galbodde Souckong realised 1*s*. 5*d*. and 1*s*. 5½*d*., and the same price was paid for Kandaloya Pekoe Souchong. The dust and fannings from Galbodde and Kandaloya fetched 1*s*. 2*d*. and 10½*d*. per lb. In the opinion of the Melborne tea brokers there is no great opening there for dust, and they recommend that broken Pekoe be not separated, but shipped together, and that if any quantity of dust were placed upon that market the price, would fall very considerably.

As regards the best size of package to suit the Australian market, the Ceylon Commissioner gives 50lbs. as the most appropriate weight, but according to the broker's report in the same paper, they recommend packages of one uniform weight say 35 lb. nett. Quarter chests, it is said of 20lbs. each, find a few buyers, but boxes of 10 to 11 lbs. each, generally meet a quick and ready sale; whilst tea in packets of one or two lbs are considered very objectionable. Altogether the results of tea shipments to Australia must be regarded as exceedingly favourable to the growers; the prices realised leave a handsome margin of profit to the planter, and when viewed in comparision with prices obtained in the London market they will assuredly influence a good many consignments to the Southern Colonies where we have very little doubt that within a few years, Indian and Ceylon teas will usurp the position now occupied by the China article.—*Ceylon Observer*

COFFEE.

COFFEE STATISTICS IN INDIA.

"COMPLETE returns for 1877-78 of the coffee cultivation in British India have not been received. It is understood that coffee of very good quality is produced at Chittagong, where the land and climate are said to be well suited to the cultivation of the plant, but no particulars have been supplied to the Bengal Government by the planters. There are no coffee plantations in any other part of the province of Bengal, though a few plants are sometimes seen in private gardens. In British Burmah the Roman Catholic Missionaries at Toungoo have a successful coffee plantation, but no information has been given with regard to it. Beyond the fact that 128,438 acres were under coffee cultivation in Mysore during 1877-78, there is scarcely any other information available on the subject. The season was a bad one for the production of coffee, and the value of the quantity manufactured is estimated to have been only £158,952 in 1877-8, as compared with £317,143 in 1875-76. About 45,150 acres were under coffee cultivation in Coorg during 1877-78. In coffee lands there was an increase during the year of 2,658 acres of assessed land in occupation and 1,000 acres of planted land. The actual area of planted and unplanted land in occupation by European and native planters respectively, was:—For the European, 26,459 acres, and 21,757 acres; for natives, 18,681 acres, and 20,086 acres. Labour was plentiful, but owing to the reduced condition of many of the coolies, who were mostly emigrants from the neighbouring famine, stricken province of Mysore, there was a general complaint on the part of the employers that the work turned out was poor. As regards the Madras Presidency, the year 1877-78 was very unfavourable to coffee, except in the Ouchterlony valley and the South-East Wynaad; the crops there were singularly good. In the greater part of the coffee area the rainfall of March and April 1877, brought out heavy blossom, but this was destroyed by the succeeding drought. It is understood that coffee sold during 1877-78 at over £100 a ton, if of the best quality. Over 33,000,000lbs. of coffee were exported from the Presidency in 1877-78."

A SHORT ACCOUNT OF COFFEE PLANTING IN JOHORE.

THE territory of Johore, as most people in Ceylon are doubtless aware comprises the extreme southern portion of the Malay peninsula.

PHYSICAL FEATURES.—The physical aspect of the country is that of a low undulating plain, while here and there rise small ranges of hills from 500 feet to 600 feet high, covered with virgin forest, and at wider intervals, detached mountain chains shoot up suddenly to a height sometimes of over 3,000 feet above the level of the sea. It is on these mountains that land for coffee planting has been selected.

G. PULAI.—The first range to attract the attention of coffee planters was Gunong Pulai, as being the most accessible and the nearest to the town of Johore Bahru, the distance being not more than 20 miles by boat and riding road. Its highest point, St. George's Summit, is 2,050 feet above sea level, and the next in height, St. Michael's Peak, is 1,950 feet in elevation. The latter has been cleared of jungle, and a fine view of the Straits and the island of Singapore can be obtained. The survey of this range, after great difficulties, chiefly through want of suitable labour and means of communication and transport, has just been completed and its acreage is found to be 14,14la. 1r. 38p. Of this about 1,000 acres have been felled and are being planted up. On the largest of these clearings a comfortable bungalow has been erected, to the great improvement in health of its occupants who were living previously in a temporary hut built in a hollow by a stream. The coffee in this clearing was looking wonderfully well a mouth ago and promising well for the success of the enterprise in Johore.

BATUPAHAT.—The next start was made at Batupahat, a place about 60 miles up the coast from the town of Johore, and the same distance from Singapore. The hills here rise from the sea coast and extend inland in small detached ranges of from 6,000a. to 8,000a., their highest elevation being about 1,500 feet. They are accessible from the sea and from the Batupahat river which winds among them and its navigable for small steamers for 8 or 9 miles from its mouth.

About 200 acres are roaded and planted here, and another 800 acres were being felled and burnt off in September last, probably now in course of being holed and planted, Chinese labour in this locality being more easily obtained than in other districts.

Survey orders in this district have been issued for about 16,000 acres, a great portion of which has been completed already.

G. PANTI.—Gunong Panti, consisting of 10,807 acres, 8,307 of which have been taken up and the little plants issued, was the next to engage the attention of coffee planters. Here 200 acres are felled and burnt off, of which 100 acres on Messrs. Dew and Mackenzie's estate are partly, if not by this time wholly planted up and roaded. The top of Gunong Panti, consisting for the most part of a well watered flat 1,237 acres in extent, and cut off on three sides from the rest of the hill by cliffs 100 ft. high, is reserved by the Maharajah's Government for the purpose of establishing a sanatarium after the manner of Nuwara Eliya. Its average elevation is between 1,200 ft. and 1,500 ft.

The soil on Panti is with the exception of some parts of Pulai, with which it is identical perhaps the best of what has hitherto been selected. Starting from Johore Bahru in the morning G. Panti can be reached, the same day. Fifty miles of the distance, for the most part up the river Johore, can be travelled per steam-boat, to Kotta Tingi, a village on the river bank where a resthouse has been erected. From Kotta Tingi to the resthouse at the foot of the hill, a distance of 6½ miles, must at present be travelled on foot, but a bridle-path is being traced and cut.

GEOLOGICAL FORMATION AND SOIL.—The formation of the country, in the portions explored by the writer, is mostly granite, passing, in parts of Pulai and on G. Panti into the old red sandstone or Devonian, the soil

being remarkably free and light, so much so that a stick can in most places be thrust in by the hand to almost any depth, and in places where it has been necessary, in excavating sites for buildings or in roading, to penetrate to a depth of 8ft. or 10ft. the same character has prevailed, as shown by the roots of trees, both large and small, which even at this depth cross each other in every direction.

The size of the forest trees, far surpassing anything of the sort in the hill county in Ceylon, the absence of thick undergrowth and the number and variety of the ferns also go far to point out the richness and fertility of the soil.

CLIMATE AS REGARDS COFFEE.—The climate seems also very favourable to the growth of coffee and similar products, to judge by the thriving appearance of the young clearings on the hills and the native plantations, few however and far between, on the banks of the rivers and sea coast. Elevations seems to be a matter of indifference to the coffee tree here. In Johore Bahru, at the bungalow of the manager of the Maharajah's steam saw-mill, situated on a hill 50 feet or 60 feet high over-looking the sea, there are two or three coffee trees from eight to ten years old which are constantly loaded with crop, and this in spite of the fact that until a year ago when Mr. Watson pruned and handled them, they had been allowed to grow perfectly wild. I am told also that a few miles up the coast there is a small native plantation of coffee, the roots of which are occasionally washed by the sea at high water, in spite of which proximity they continue to bear apparently as well as if they were situated several thousand feet above it. This is doubtless as much due to the fertility of the soil as to the absence of long seasons of drought.

RAINFALL.—In the Peninsula, the rainfall varies form 4 inches to 18 inches per month, and it is rare, even in the hottest months, for a fortnight to pass without one or two light showers. In the wettest month also it seldom happens that the rain continues a whole day without intermission. At times it will rain a whole afternoon and the greater part of the night, but the morning is usually fine for a few hours when owing to the looseness of the soil but few signs remain of the previous rain, however heavy it might have been.

WIND.—Storms of wind are unknown in Johore and with the exception of occasional gusts the wind never rises above a breeze.

Means of communication are not as yet in a forward condition, but much has been accomplished and more is being done, and it is hoped that the railway from the town of Johore to the foot of G. Pulai, commenced by the Maharajah some years ago and formed for two-thirds of the distance, will be completed by the time the first crops are being gathered. At present this railway is being utilized as a cart road along a portion of its length. A cart road is intended to be constructed also in the Batupahat district, starting from the river and winding its way through the coffee estates for 8 or 10 minutes, while G. Panti will also be similarly favoured before long, it is hoped by the conversion of the bridle-road, now being traced and constructed into the cart-road it is ultimately destined to be.

LABOUR.—The labour question has, notwithstanding the efforts of the Maharajah and the planters, been the chief difficulty hitherto in Johore. At first, as is often the case on opening new estates, even in Ceylon, there was much sickness among the coolies, but this state of things has very much improved, and sickness had almost entirely disappeared when I was last up-country, the hospital established in Johore Bahru being empty.

Much delay in planting operations was naturally the result of this sickness among the coolies but now what with Malays, Chinese, and Klings, or Tamils and the energy displayed by Messrs. Watson and Falconar on Pula, and Batupahat, and Messrs. Dow and Mackenzie on Panti the work of clearing, planting and building, &c., is progressing rapidly, and the final completion of the 2,000 acres, more or less, already burnt off cannot be long delayed.

Altogether the prospects of the planters in Johore are very encouraging, and it is not difficult to foresee in a year or two, where the success of the new enterprise shall have been practically demonstrated by large crops combined with cheap labour and transport, a great rush from all parts to take the remaining available coffee land in the Maharajah's territory.—*Cor. Ceylon Observer.*

CACAO.

CACAO.

(To the Editor of the Ceylon Times.)

SIR,—In going through my shade of cacao clearing this morning, I came across one of many fine young plants nipped off close to the roots—my neighbour declares that this is not done by white ants, that the plants are first really killed by grub, and that the ants attack the plant immediately the sap ceases to flow, now this plant that was "felled" this morning was perfectly fresh, and by its whole appearance I could see that it had only just been bitten off. I searched all about the roots and round the plant, but could find *no grub*, and did find any number of white ants. I sent the plant and wrote at once to my friend and got for answer "I am convinced by long searching that primarily this bark was cut by grub, so staying the flow of sap which induced the ants to attack the tree;" convince a planter against his will, &c.

Avisawelle, October 9.

CINCHONA.

THE CULTIVATION OF CINCHONA BARK TREES IN SOUTH AMERICA.

IT is significant of the practical interest which the Dutch Government take in their Java gardens and the cinchona enterprise generally, that their Consul in Bolivia should have sent home the long and interesting report which has been translated for our readers from the *Indische Mercuur*, and which we, this day, republish. The Consul's information fully corroborates the statement made by Mr. Ledger to Mr. J. E. Howard which the latter embodied in the interesting paper read recently before the Pharmaceutical Society. Mr. Ledger made it clear that the very first attempt at cultivation in Bolivia followed on a suggestion he made to a bark cutter, so far back as 1849. This was in the same province of Yungas mentioned by the Dutch Consul, and so largely had Mr. Ledger's friend (and no doubt neighbours) profited by the Englishman's hint to plant the rich, but bare, cinchona forest-land, that in 1878 the cascarillero reported he had for some years been cutting on his own account from cultivated trees, as much as 100,000 lbs. of bark per annum worth, at least, 4*s*. a lb. Mr. Ledger's Bolivian friend also reported that he had tried the process of partial stripping rather than coppicing his trees, and found it to succeed fairly well, 5 per cent. being the average mortality among the trees so stripped, the bare part of the stems being covered with mud. The Dutch Consul takes us further back in his report, to shew the wasteful system under which the cascarilleros worked in the "days of old," in recklessly cutting down giant forest trees from the stems of which the bark was only partially removed, while the very valuable branch bark was entirely neglected. The great impetus to cultivation in Bolivia given in 1878 occurred, strangely enough, about the time the rush took place into cinchona planting in Ceylon, Southern India, and Java. The estimate is that, perhaps, half a million plants were put out in Yungas, many of them being planted on land ordinarily used for coca, cacao, coffee, or sugarcane. The maintenance of the cultivation therefore depends very much on the relative returns from these different products, and in most cases the Consul believes that "coca" will retain its pre-eminence as the preferable article of cultivation. Still the comparative ease with which, up to a certain point, the cultivation of cinchona can be extended in its native habitat in Bolivia, should henceforward be carefully considered. The florin being, for all practical purposes, the equivalent of the rupee (at 1*s*. 8*d*.) Ceylon planters can easily compare the estimate furnished by the Consul with their local experience. He gives, Rs. 130,000 as the cost of planting and cultivating 300,000 plants, up to their fourth year apparently. These plants, are put down in rows a 5 or 6 feet apart (1,500 to 1,200 plants to the acre), and shaded with bananas during the first and second year. Experiments made in stripping, according to the Consul, do not seem to have answered, for the cultivators say they prefer their old mode of coppicing one or two feet above the ground. We are left in the dark as to the return in bark or in the crops harvested from a certain area, but the value of the product is placed at from 5*s*. to 6*s*. 6*d*. per lb. One piece of news to us is found in the exportation from South America of "false cinchona bark" to the extent of 440,000lbs. per annum worth about 2*s*. 3*d*. per lb. from which "so-called quinine wine" is manufactured. Finally, it will be seen that in respect of cinchona cultivation in Bolivia or Perú, as in the case of coffee culture in Brazil, "*the labour difficulty*" is the rock ahead. The Dutch Consul informs us that the labour force in Yungas, for instance, is barely sufficient to work what he considers the much more certain and profitable "coca" plantations. There is, therefore, little reason to fear such competition from South America, for at least many years to come, as need deter cinchona planters in the East from doing justice to their plantations or from extending the enterprise wherever soil, climate, labour supply, and a reliable variety of plants are available.—*Ceylon Observer.*

CINCHONA NURSERIES.

(To the Editor of the Ceylon Observer.)

DEAR SIR,—Having seen a good deal of cinchona nurseries in different districts during the past two years, and having some practical experience of how miserably they fail to produce a return equivalent to expectations, it has struck me that amongst the various causes that such failures may be attributable to a want of due care in selection of seed, may rank as one of the most prominent and at the same time most easily

remedied. In cinchona clearings in Ceylon, are frequently to be seen trees not more than three or four years old, laden with blossom and looking very shuck, too frequently a sure sign that they are about to die out. The seed from such trees may produce cinchona plants; but is it to be wondered if they turn out weak and sickly, dying off at an early age? There is I fear a very large quantity of such seed sold in Ceylon. What I would argue is that too great care cannot be taken in selection of seed for a cinchona nursery, the purchaser being very particular as to the origin of seed and age of parent trees. I believe this to be a point of far greater importance than the laying out of expensive sheds. I will even go so far as to express a doubt as to the necessity of going to the expense usually incurred in the laying out of cinchona nurseries, and some years, hence I believe nurseries for raising cinchona seedlings will be a thing of the past, and nothing will be used for cinchona clearings but self-sown plants. At present there are not nearly enough of such plants to meet the very large demand there is for cinchona, but might it not be sufficient in making nurseries, where practicable, to clear up a piece of jungle of all undergrowth, dig the soil well up, and sow under natural forest shade? There would doubtless be a large number of failures in such a nursery, but if only the best seed to be procured was used, I am inclined to believe quite as good, if not a better, return would be secured as is generally the case under the present system. I put forward the above opinions with all due diffidence, and shall be glad if I can only gain a due consideration for my theory from planters of ability and experience, even should the result be a unanimous condemnation of the heterodox opinions held by, yours faithfully,

SIGMA.

[Our correspondent is right generally, but we believe the drip is fatal to nurseries under forest shade. Grass, ferns, jungle branches, and coir mats, as shade, have resulted in plants whose strong roots atoned for less height above ground than those reared in sheds.—Ed., *C. O.*]

CINCHONA ANALYSIS.

(To the Editor of the Ceylon Times.)

SIR,—I send you copy of analysis of some chips of cinchona *officinalis* recently received from Mr. Elphinstone as being what is called "dead bark." It appears to bear out your theory that retarded growth favours the secretion of quinine at the expense of the other alkaloids. It is called dead bark, I believe, because the trees have died in the ground; but to appearance, it was as fresh as dried bark from living trees.

	per cent.
White crystalline	
Sulphate of quinine	1·52
Amorphous alkaloids	
Soluble in ether	·77
Quinidine cinchonidine	
Cinchonine (by difference)	·45

In making the above determination, the quinine was separated in the white crystalline form, which is the only thoroughly reliable method when the bark is intended for the manufacture of sulphate of quinine.

According to some commercial methods of analysis, a greater or less proportion of what is here reported as amorphous alkaloids, would be regarded as quinia, whereas in reality it bears a relation to quinine very similar to what syrup does to sugar. Crystallisation of the quinine in the laboratory as sulphate, is the only adequate test of what can be crystallized in the manufactory. As the question is at present engaging attention, I would submit that the direct determination of the quinine in the crystalline form should be adopted in all our analysis of cinchona bark rather than the determination of the simpler alkaloid, and calculated of the amount crystallisable as sulphate.

It has two important advantages—greater accuracy, and the planter, merchant, and manufacturer know exactly what is meant.

M. COCHRAN.

Testing Rooms,

Colombo, 22nd September 1880.

P. S.—Since writing the above Mr. Elphinstone remarks:—"It is a most satisfactory analysis and bears out my expectations as to the value of *officinalis* grown at the height of——estate. Doubtless the retarded growth is most favourable for the development of the quinine."

DR. MOENS' VISIT TO CEYLON.

DR. MOENS, the Java Quinologist, has come and gone. His stay was not sufficiently long to enable him to visit some of the most favoured districts in the Island, his tour being necessarily confined to Uda Pusellawa, Maturatta and the new districts on his way back on the return journey to Navalapitiya and Kandy. In Uda Pusellawa and Bogawantalawa, the learned traveller saw some of our best soil, and some of the finest specimens of cinchona to be met with in the island, of the *Officinalis succirubra* and the *Hybrid*. No one expected that Dr. Moens would have found the soil in Ceylon equal to that of Java, although the result of cinchona cultivation in certain of our districts and notably so on the Uva side of the country, is as satisfactory as in many parts of Java. The rapid growth and development of the trees were noticed by the traveller with admiration, and it is evident from brief notes left behind him, as well as from conversation with the proprietors of the estates he visited, he was well pleased with what he had seen in our fertile island. At the conclusion of this Indian tour on which he started yesterday, the Dr. will no doubt prepare a report of all that he had seen from notes taken during his journey, when he will be able to elaborate his ideas upon the comparative progress in the different countries he will have visited, and for the perusal of this document, we shall look with considerable interest.

The following very general remarks on his visit to the interior, are from our daily contemporary:—

"Soil, though very different from the Java soil, is very suitable for the growth of cinchona. Trees grow as well as they do in Java, and *officinalis* even better.

"Where trees are planted in suitable soil, they do not go out after some years. Where this is the case, it is due to bad soil,—or in some places to the exposure to wind.

"As to the elevation above sea level, the range is very wide. Succirubra grows best about 5,000 ft., but can be planted from about 3,000 to 5,000 ft. Ledgeriana grows in Java best from 3,600 to 5,000 ft., and It think' as the climate of Ceylon is much the same as that of Java, that the same elevation here will suit Ledgeriana best, Officinalis should be planted from about 4,800 to 6,500 feet.

"These are the best elevations, but they may, under favourable circumstances, be surpassed, either going lower or higher. 'There is nothing like trying,' but it ought to be done on a small scale at first."

It will be seen from the above remarks that Dr. Moens states the lowest altitude at which *Succirubra* may be grown, as 3,000, which is higher than has been believed to be the limit of *Succirubra* cultivation, and certainly it has not generally been considered that this variety can be advantageously grown as high as 5,000 feet, as though no doubt it may be grown higher in the Ourah districts than in others.—*Ceylon Times.*

THE CULTIVATION OF *CALISAYA.*

WE make no apology for reproducing, (on the next page,) a rather lengthy contribution to the *Pharmaceutical Journal* by Mr. John Eliot Howard, F.R.S., F.L.S., on the cultivation of Calisaya, a subject urgently and pre-eminently important at the present moment, when large areas both on the Nilgiris and in the Wynaad are being brought under cinchona. Whether the cinchona planter will derive a profit or a loss from his enterprise depends, in a great degree, upon the intelligence he brings to bear upon the subject of selection, one, unfortunately, that is not determined for him with precision, but in which he must act upon the best information available. Speculators are solicitous merely to cover an enormous surface with no matter what variety and trust to the existing *furore* to sell to advantage to some novice with more money than brains. Mr. Howard gives excellent advice when he says "that the only chance for Indian cultivation in the future consists in the choice of superior sorts and the efficacy of high cultivation." The varieties of the Calisaya are so rich in quinine that they are worth cultivating at almost any cost. Mr. McIvor, than whom no better authority can be quoted, thought this class of plants was unsuited to the Nilgiris because it developed a spindly and bushy growth, instead of attaining the proportions of a tree as in its native habitat. In the Wynaad, however, exist conditions of climate and soil that promise better success. Large numbers of the *Ledgeriana* are being introduced there at enormous cost. We have heard of planters paying as much as Rs. 500 per 1,000 for them, but many thousands of inferior sorts are also being put out, a procedure that may result in future disappointment.

The drainage difficulty is naturally solved for us and the danger from "wet feet" to Calisaya obviated by an undulating surface which carries off superabundant moisture so prejudicial to this variety. As regards high cultivation, there are happily few planters who believe that you can go on cropping for a series of years while starving the tree. We have an unmistakable instance near at hand of killing the goose that lays the golden eggs in the case of the Government Cinchona Estate at Dodabet. Since this property was opened it has been innocent of manure, while repeated crops of bark have been taken. The result is apparent in the overgrowth of lichens and the decay of the lower twigs of the trees. The condition of the plantation may not be irremediable, but the Government has demonstrated what is to be avoided rather than imitated.

Mr. Howard does not appear to be apprehensive of the supply of cinchona bark exceeding the demand, notwithstanding the millions of plants already and annually put down. The more delicate and valuable varieties of cinchona are subject to a mortality which will go far, in a few years, to confine the cultivation to the *bona fide* planter with perseverance and intelligence to cope with this serious drawback. Mr. Howard estimates the mortality at 90 per cent., and we have proof that it cannot be arrested

by any known means. A few years ago a whole patch of Calisaya, some five acres in extent, died out at Neddiwuttum without any visible cause for the same. It may be here as Mr. Howard affirms was the case with the plant that formed the text of his paper, that the roots struck into the gold and uncongenial subsoil. Whatever the cause this recognized mortality will contribute in no inconsiderable degree, to keep up the price of bark.

Of the astounding progress in cinchona cultivation in Ceylon, Mr. Howard takes but a gloomy view. His forecast for 1885 of the quinine market if correct, must be most disheartening to those planters who have neglected coffee for the more seductive prospects of cinchona. Doubtless much of our Nilgiri and Wynaad bark will be similarly noted as "rubbish," unless a sound selection is now made and the valuable varieties only planted. The cinchona planter, who hopes to be successful, must be constantly on the look out for sound and scientific information on the subject. The best mode of harvesting the bark is still in the region of experiment. Natural bark, mossed bark, renewed bark and root bark are matters that still puzzle the planter. It will not do for him to consign these questions to the future. He must decide at once, and on the meagre information available, or the loss may be irreparable. From Government we can get little, the generally received opinion being that as in the case of tea in the north of India, it has misled the planter, who is no longer disposed to follow its teachings. One precious document, hatched in the inner recesses of the Under Secretariat, is about at this moment to see the light. It is an epitome of Captain Campbell Walker's report on the cinchona Plantations, penned in 1878. Captain Campbell Walker denies its paternity and as the public are ignorant of the original, it is not in a position to judge of the bantling. This officer, however, is not disposed to permit a spurious production to be given to the public in his name, and the public after a bitter experience is not disposed implicitly to follow the teachings of a Government, unmistakeably in the position of the "blind leading the blind."—*Ceylon Times.*

MR. JOHN HOWARD ON THE CULTIVATION OF *CALISAYA*.

THE death and *post mortem* examination of a small tree of *Calisaya anglica* will furnish a suitable introduction to some comments on the subject of this paper.

I append a photograph of this tree taken in the autumn of 1870 ; form which it will appear that it was in luxuriant health a few months since. On returning home last month, I noticed a very unfavourable change in its appearance, and detected some white spots on the bark arising from fungus, which I knew from previous experience to a fatal indication of disease. On further examination I found that canker had invaded the plant to a serious extent ; and after trying in vain some heroic remedies, I determined to root up the callisaya, and if possible gain some useful information as to the cause of its death.

The age of this small tree was eight years. The height between seven and eight feet, but would have been much more, had I not been compelled to cut off the top some years back in accordance with the requirements of my conservatory.

Before doing this, I succeeded in taking a strip along this upper portion, and renewing the bark under moss as practised in India. The girth of the stem at the base was 9½ and inches about 6¼ inches at the submit (where cut off). The result of the analysis of the bark of my tree was as follows :—

Calisaya Anglica Quill=1·25 Sulphate of Quinine, 0·70, Cinchonine, 0·15 Quinidine.

Calisaya Anglica Stem Bark=3·20, Sulphate of Quinine, 1·50, Cinchonine 0·32 Quinidine.

Calisaya Anglica Root Bark=3·95, Sulphate of Quinine, 1·00 Cinchonine, 4·00, Cichonine 0·27, Quinidine.

This must be considered satisfactory for a tree grown under glass in England.

I send the lower portion and also the renewed summit for inspection, together with some pressed leaves showing the character of the foliage. These were taken off just before the tree was rooted up ; and I may notice as a feature of the disease, that the petiole separated with a brownish scar, the leaves falling as those of deciduous trees in autumn.

As regard the cause of this complaint, which seems generally to supervene after my cinchona plants have attained a certain age (say, as in this case, about eight years), I was not able to learn anything very definite. I suspect that the oxidation of the cinchotanic acid may take a wrong direction,* and instead of contributing to the formation of alkaloid, may produce the brown discoloured patches which extend upwards from the roots through the midst of the bark ; but the source of the mischief seems to be in the roots themselves, the small fibrillae of which perish. It has been supposed that this arises from a redundancy of moisture ; but I have two fine plants of calisaya, one of the *vera* (published as such by Sir Jos. D. Hooker) the other of *Ledgeriana*. These have shown yet no signs of the malady, though growing in the same bed of earth.

I learn from the report of a recent visitor to the plantations in Java * that they have there '*no* canker and few trees die from wet feet, for the land is elaborately terraced before it is planted with cinchona.' 'The Ledgeriana grow best in the soils of that country.' The great superiority of the Java soil possessing as it does such abundant elements of fertility, is particularly noticed. 'The weeds which are very abundant are cut down three times a year, and left to decompose, forming an additional source of fertility to the plant ; whilst in their very growth they are supposed to be useful. They keep the soil together, they catch and retain the rain and dew, prevent wash and hinder the rays of the sun from beating down on the bare surface of the soil and keep it in the condition nature intended it to be in. They are also a safeguard, for if you denude large tracts of country of every kind of vegetation, except the one kind you are cultivating, you concentrate on the devoted head of your favourite type of vegetable life, all the attacks of all the enemies of vegetation which float in the air or which burrow in the ground.' So much in the defence of the weeds ; but it must be borne in mind that let them consume as much as they can there still remains enough and to spare in its richness ; 'neither the coffee nor the cinchona could possibly look better or grow more luxuriantly if they had all the elements of the soil to themselves without any contest or opposition.' In the opinion of this observer the tree will find no spot in Ceylon, excepting‡ a few parts of Uva, capable of affording it anything like the nourishments it requires to develop a bark yielding on analysis such magnificent proportion of the best alkaloids.

Too much stress, however, ought not to be laid on this peculiar advantage, for on the Nilgiris, though the trees grow bushy and spindly in habit, the quality of such bark as was yielded appeared to us excellent. Quite recently also barks of Ledgeriana has been sold in the London market (said to be from Darjeeling at the high price of 14*s.* 8*d.* per pound. The development in that climate was apparently slower, but its looks as if trees in their full maturity might rival those from Java. In this latter region it appears that 'no stem or root bark is ever exported that is not the produce of a tree at least eight years old and generally of still greater age.'†

At this age, Mr. Moens, calculates the average yield for officinalis to be 2lbs. per tree, against 4lbs. from Ledgeriana and 6lbs. for succirubra. Ledgeriana is the prince of all, for it appears that even at the low average price of 6*s.* per lb., the thirteen years old plantation, if now rooted up, would yield an average of at least £2,000 per acre. Mr. Moens make it £4,000. But there is no idea of rooting up trees which, under the processes of gradual removal and renewal of bark, will yield a perennial flow of wealth. In this respect the management appears to be much better than in British India. Mr. Moens says : 'Our 8½bouw of Ledgeriana has given within thirteen years till now 34·619 half kilograms, say 38·800 English pounds, by thinning, coppicing, and scraping.' 'And if you saw the gardens at present, you would ask where this bark had been taken, as the plantation is quite close and regular. We took only what was too much, and would hinder the growth of the finest trees.'

The size of these finest trees is remarkable. They speak of a succirubra tree of fourteen years old, 63 feet high, and 3½ feet in girth ; a calisaya tree seventeen years old, 60 feet in height and 3 feet in girth, and a Ledgeriana thirteen years old, 48 feet high and 3 feet in girth.

I will now contrast with these results others obtained in the native country of the calisaya, in consequence of suggestion of Mr. Ledger, who thus records them in a letter to me under date December 10, 1879—

In December 1849, I was at the farmhouse of a contractor of mine for delivery of a large quantity of bark, in the Yungas of Bolivia. When conversing one evening on the distance that bark had then to be brought out of the forest to where we then were, my friend observed, pointing to the slope of a high mountain on the opposite side of the gully or canon : 'In my father's time, and when I was fifteen or sixteen years old, from the sides of yonder mountain (*cerro*) we were for two years cutting the best bark I ever saw, almost all was 'rejo.' I then said : 'Such being the case why do you not then plant there 10,000 or 20,000 plants ? It is your own property, and, living near, you would in that way have a good fortune for your children.' He did plant some 6,000 by March; and in the following year 10,000 more. In reply to inquiries, his letter of September 1878, I only received in August last. He says : 'Not only I, but all the family have very good reason to remember your visit to San Jose. Since 1875 we have cut 500 quintals of bark yearly, and owing to demand, have sold at an average of 200 dollars per quintal (equal to 4*s.* per lb.), and there is "cascarilla" (bark) in abundance for ten years. We have planted many thousands of trees since you gave us the idea,—and the same has been done in Sorata.' "

I have much reason to believe that the supplies thus obtained have found their way to the English market, and that the details above given are correct. These, it will be observed, indicate a lower average quality than that of Java. This perhaps coincides with a more rapid growth of the trees, for Ledger's correspondent says : "We have not weighed the bark taken from each tree," which, however, must be much older than those in Java ; "yet I should say that many yielded 3 or 4 quintals of the three classes, *tabla, charqui* and *canuto*. The bark is not all of the best though every plant was picked."

* It is important to seal up any accidental wound or amputation, otherwise the sap wood is liable to injury.

* *Ceylon Observer*, June 17, 1880.

† *Ceylon Observer*, June 17, 1880.

‡ Ibid June 12.

In a subsequent letter, the same correspondent says: 'For some eight years we have stripped half the bark off some thousands of trees; about 5 per cent. die. At first we covered the wound with plaintain leaves for a year or fifteen months. We find now it is best to plaister the stripped side with mud (barro) mixed with plenty of chopped straw of grass, and it answers admirably. When the new bark is well grown, the mud covering falls off.

I do not think any of this bark (as imported into London) has had the appearance or ... the richness in alkaloid of the true Ledgeriana ...ced. Mr. Ledger says: 'I feel convinced in my own mind that no white man would or could succeed in getting splendid seed as my faithful Manuel did. In fact, and as the good ... fellow repeatedly told me, he got seed from particularly fine old trees that we had together seen and sat under. The splendid old tree in Fr. Simon's yard we often (in 1850-51) used to look up and wonder the age it could be. It was covered with silvery bright pink moss.* We put its age at over five hundred years. I have often calculated with Manuel that it would yield fully 15 qqs. dry bark of the three classes.'

It was in this district probably that Dr. Weddell obtained the specimens I have referred to in my 'Origin of the *Calisaya Ledgeriana* of Commerce, as in the years above referred to Mr. Ledger says they were together in the above districts. I do not believe these were exactly identical with the Ledgeriana, though approaching very nearly to it.

The specimens given to me by Dr. Weddell were as follows:—

Calisaya viride	Prov. de Yungas, 1851.
„ zambita	
* „ morada	
„ morada	Prov. de Larecaja, 1851.

Ledger thus describes† what calls the "rojo":—"When in flower the leaves are red underneath. When the seed is ripe and the leaves falling they are a dark purple. Old trees in particular have one the branches a species of rough moss of a brilliant scarlet colour."

This is called *Hypochnus rubrocinctus* and is represented on the Calisaya in Goebel's *Pharmaceutische Waarenkunde*. It used to be looked upon by dealers in London of a necessary indication of the best calisaya. Ledger also speaks of the red and dark green leaves as peculiar to this cinchona "I have often" he says, "seen, when in the yungas, from the fork of a high tree the *manchas* far away devoted most clearly by the wind discovering the red colour under the leaves." Mr. Ledger sent me in 1877, specimens of calisaya, two of which were of the 'rojo' sort with white flowers; but all were unfortunately lost in transit. The white flowering calisayas would probably be the true Ledgeriana, and gathered near the banks of Mamore‡ I am more and more inclined to think that the true Ledgeriana belongs to Eastern Bolivia, in which district the River Mamore belongs. It will therefore be understood that the cultivation in Bolivia although comprising fairly good qualities of calisaya is not that of *Ledgeriana*, nor can it yield such remarkable results.

(To be continued.)

CINCHONA CULTIVATION IN JAMAICA.

(From the Colonial Standard and Jamaica Despatch.)

PRESSURE of matter has made it impossible for us to take earlier notice of the Planting Memorandum by Mr. Morris, Director of Public Gardens and Plantations, which appeared in the Government *Gazette* in connection with Account Sales of cinchona bark from Jamaica—sold at public sale for account of the Crown Agents for the Colonies. The result of the sale and remarks thereon are highly gratifying to all who have taken an interest in the establishment of the cinchona enterprise in Jamaica, and our readers will understand that we experience special satisfaction at the measure of success that has already been attained, inasmuch as this journal from the very beginning, expressed confidence in the practicability and profitable issue of the new industry, and did all in its power to remove the doubts, fears, and prejudices of those who condemned the enterprise and described the amounts expended in forming the plantation as money recklessly misapplied and ruinously wasted. Now that the successful cultivation in this colony of an important article of commerce has been fully established, we think it right to make suitable acknowledgment of the shrewd perception and resolute purpose displayed by Sir John Peter Grant in discovering the adaptability of the soil and situation of our Jamaica mountains to the cultivation of a valuable product which is particularly fastidious in regard to the requisite conditions of elevation and climate, and in making prompt and ample provision for the maintenance of the necessary nurseries and plantations and for giving the experiment a fair trial. It becomes us, too, at the present moment, to do justice to the energy, ability, and zeal of Mr. Robert Thomson* who underwent, so to speak, the burden and heat of the day in being called upon to assume the care and responsibility of the initiatory and tentative measures and proceedings which form such an important portion of the elements or conditions of qualified to perform the duties of an important position, and more especially to make his knowledge and experience the means and instruments not, only of advancing the scientific character and prosperity of his department, but of bringing the facts and bearings of the great natural capabilities of the colony within the practical ken and use of the general community. In the memorandum which accompanies the account sales of the last consignment of cinchona bark, Mr. Morris gives a plain, explicit statement of the results of the sales, the relative merits of the different species and the prices obtained for them, the elevations best suited for the cultivation of the several kinds of bark, and the cheapest and most effective process of drying the bark prior to shipment. The account sales, we observe, refer to a fourth consignment, but we are informed that a subsequent consignment of 6,000 pounds was despatched from the plantations on the 24th June, which would close the shipments for the current year. Up to date, not including the last consignment, the Director of Public Gardens and Plantations gives the following as the results of the cinchona sales:—

Quantity of bark shipped	... ...	21,099lbs.
Gross amount realized	... ...	£4,066 17s. 11d.
Net sum realized	... ...	£3,890 11s. 8d.

The *Cinchona officinalis* is, according to Mr. Morris' memorandum, by the far most valuable of the three kinds of bark forwarded to the Home mraket. For the sake of clearness and brevity, we transcribe the following remarks from the memorandum: "The prices realised were the highest yet obtained for grey bark, *viz.*, 7s. 6d. per lb. for "good quill" or trunk bank. Root bark sold at 7s. 9d. and 8s; and twig 2s. 9d. per lb. The average price for the various qualities of grey bark (*C. officinalis*) was 6s. 5½d. For yellow bark *C. calisaya* the prices realized were 4s. 6d. and 3s. per lb.

For Red Bark "good quill or trunk bark realized 3s. 6d. and 4s. 4d. per lb. Root bark 3s. 4d., 3s. 7d, 3s. 8d., and 3s. 10d., and twig bark 1s. 3d. per lb. The average price for the various qualities of red bark was 3s. 10d. per lb. The average per lb. for the whole consignment was 5s. nearly."

The grey bark, (*C. officinalis*) as Mr. Morris remarks, "still maintains its position as the most valuable of the three," but the grey bark, like all precious commodities or products, is subject to harder and more restricted conditions of cultivation than the cheaper and more common species of cinchona. It is natural that all who wish to try their hand at the new enterprise should prefer to commence the experiment with the remunerative grey bark, but it must be borne in mind that it can be successfully cultivated only at high elevations ranging from 4,590 to 7000 feet—a circumstance which, of course, considerably limits the area of productive cultivation and the scope of industrious effort. The cultivation of cinchona seems to be analagous to that of coffee in respect of the effects produced by difference of elevation; the finer quality of each showing a special adaptation to the high mountain ranges, while the less valuable kinds flourish in greater abundance at comparative low altitudes. It is pleasant, however to know, that Jamaica enterprise will meet with a very satisfactory remark if it turns its attention to the red bark (*C. succirubra*) which Mr. Morris states; "can be successfully grown at all elevations above 2,000 feet," the results of the sales showing that Jamaica red bark," at ten years old, is equal to the best produced either in South America or the East Indian plantations. It is right, too, to bear in mind that there is a considerable acreage of land possessing the requisite conditions for the successful cultivation of the "grey bark," and it is no small incentive to those who have the means and opportunity of planting this species, to be told that, "at the prices above mentioned grey bark," grown at elevations of from 4,500 to 7,000 feet would realize at the close of 8 or 10 years, at the rate of £500 per acre." Cinchona cultivation has, thanks to the energetic and enlightened efforts of Government, been proved to be a genuine success in Jamaica; and it now behoves private capital and enterprise to follow up the work so auspiciously begun, and add another valuable product to the unrivalled staples of the Colony.

EXTRACT FROM MEMORANDUM BY THE DIRECTOR OF PUBLIC GARDENS AND PLANTATIONS.

It is evident that where the grey bark can be successfully cultivated, it is likely to prove the most productive of the kinds at present under cultivation in Jamaica. At the prices above mentioned grey bark, grown at elevations of from 4,500 to 7,000 feet would realise at the close of 8 or 10 years, at the rate of £500 per acre.

But by a careful system of planting and cultivation, a first return should be realized from prunings and thinnings, at about the fifth year. It will be noticed that at the recent sales twig bark of this species realized. 2s. 9d. per pound, which fully bears out the possibility of an appreciable income from cinchona plantations before the trees are actually cut down or coppiced.

With regard to the red bark, (*C. succirubra*) which can be successfully grown in Jamaica at all elevations above 2,000 feet, the results of these sales show that Jamaica *Red Bark*, at ten years old, is equal to the best produced either in South America or the East Indian Plantations. If cultivated in or near coffee lands, or in moderately sheltered situations where the soil is not clayey, this bark on account of the extensive area available for its cultivation in Jamaica would become, in time a most valuable product.

The yellow bark, the produce of trees which have hitherto passed at the Plantation as *C. Calisaya*, is evidently not the true yellow bark of commerce. The prices realised, viz 4s. 6d. and 3s. per pound though

---

* A tree of *Hasharliana* aged seventeen years gave Moens 95 lbs. of dry bark.—*Ceylon Observer*, June 14 1885. *Pharnas Journ, and Trans*, March 13, 1880.

† In letter November 24, 1875.

‡ See Ledger's letter December 22, 1874.

* This is the gentleman who has just gone on a visit to the Cinchona Forests of Bolivia with, among others, a commission from the *Ceylon Observer*.—Ed., C.C.

success on which every new undertaking, to a greater or less extent depends.

We are pleased to find in Mr. Thomson's successor, Mr. Morris, a gentleman who by his technical training and broad liberal culture, is admirably good, point to the conclusion suggested indeed, by their appearance in the Plantations that these trees are probably a hybrid variety between *C. officinalis* and *C. succirubra*. As they appear to thrive at the same elevations as *C succirubra*, their cultivation will be kept up for further trial. In the meantime efforts are being made to introduce the true yellow barks from Java and India, and establish their cultivation in Jamaica.

The most encouraging feature in the present sales is the fact that all the bark despatched in April was "sun-dried" bark. Considerable discussion has taken place during the last six years in India, Java, and Ceylon with regard to the proper method of drying cinchona bark. Some maintain that under exposure to strong sunlight the bark deteriorates and loses some of its valuable alkaloids. On the other hand the advocates of "sun-drying" affirm that in order to preserve the chemical components of the bark intact it should be dried as rapidly as possible before any internal fermentation takes place. As cinchona bark could not be dried here *artificially*, except at a considerable cost, it was most necessary to test its value when dried by full exposure to the sun. The result as shown by the present sales, is most conclusive. In competition with artifically dried and other barks it is satisfactory to find that Jamaica "sun-dried" bark obtained the *highest prices*. It may therefore be safely assumed that cinchona bark cannot be dried too quickly or too thoroughly. To this might be added that it should be packed *perfectly dry* and despatched with as little delay as possible.

TOBACCO.

TOBACCO CULTIVATION IN CEYLON.

TOBACCO, says the *Ceylon Times*, is by no means a new introduction into this country, but lately the cultivation has received an impetus by the introduction of the finer varieties of leaf, and it is now certain that in the drier parts of the island a leaf may be picked retaining all the characteristics of the more delicate kinds. In Badulla tobacco was formerly grown to a considerable extent, and the Badulla cheroots were well known and justly appreciated; now-a-days, however, they are rarely, if ever seen, and the cultivation has been to a very large extent allowed to lapse. To Messrs. Tytler and Ingleton is due the honor of having taught the Doombera villagers how to roll cheroots, and the Doombera tobacco, although a coarse kind is so well cultivated, and the cheroots so carefully rolled, that they are now universal favorites throughout Ceylon, it is, however, evident that no high district in Ceylon will over compete with India, or turn out leaf that can do more than partly supply the local market. To ensure a fine and delicate tobacco, a certainty of long dry months is absolutely necessary, and irrigation and heavy manuring, or at least a considerable acreage of virgin soil are also indispensable to ensure the best tobacco. In Jaffna most natives have a small patch of tobacco round their houses which is watered and tended carefully through the hot months, and the ground is manured very heavily before the young plants are put out, the leaf being worth some 31 cents, a lb. If the natives would use care in selection, there is little doubt but that Jaffna, and a large portion both of the Northern and Eastern Province might as easily be made to produce a high class of tobacco, and not the coarse leaf which is now the speciality of the Northern Province. Some time ago a friend of the writer introduced Maryland tobacco, and found that his few experimental plants thrived well, and the leaf assumed the light golden color, and the soft texture that is peculiar to the variety.

Let the Tamils, who have shewn themselves to be enterprising and industrious, give full consideration to this subject, remembering that a leaf that has the qualities mentioned is worth 72 cents, a lb. being three times as much as the present Jaffna leaf, and for their guidence let them study the following rules written by one of themselves in the Madras report for 1874.

TOBACCO.—"The plantation should have the advantage of plentiful irrigation. Such water may be somewhat brackish, as brackish water is preferable to any other. The well must be such as to afford a constant supply of water. There should be no fear of failure in this respect. Sometimes it is quite impossible to say the quantity of water required for irrigating land as so much depends on the weather climate and the quality of the soil and sub-soil. The maximum extent of land that may be safely irrigated by one ordinary spring well, about 8 feet in diameter is two cawnies. Sometimes tobacco is cultivated on the bank of a river; it grows on such land without much manure being used. The rich alluvial deposit that is accumulated there becomes an active agent in stimulating the growth of the crops. The produce so raised by means of fresh water is not esteemed for its flavour, so much so as the other raised on land irrigated with somewhat brackish water. The drawback incidental to such plantation is ravages of gubar. They attack the plants when they grow vigorously. Unless active measures are taken towards their destruction on their very first appearance the crops are seriously injured. Pick them off and kill them; this is the best preventive.

Copious falls of rain when the crops are near maturity are sure to impair, their quality, for such moisture wastes the clammy exudation that form over leaves through the pores. Rainfall is highly beneficial to the crops when young.

One great point to be kept in view is to reap the crops when they have attained full maturity. The tobacco is never worse than when the plants are cut before they are matured.

Plants when cut down should be exposed to the rays of the sun for a few hours only to deprive the leaves of their bitterness, and not so long as is done in some places.

The main object that should be kept in view while the curing process in being conducted is that the tobacco should be caused to sweat well and ferment of heat moderately.

My cultivation has been thus :—

While the ploughing operations were thus under progress, a separate small plot of high ground of rich soil was selected for seed-bed; this was well dug up, stirred and loosened and manured with well-decayed manure, and then smoothed. The plot was divided into twenty-five beds. The seed was sown on the 14th or 15th November. On the eve of sowing, the beds were moistened and rubbed over by the hand with a mixture of decayed cattle-dung and water. As the seeds were extremely small, they were first mixed largely with dust and then sown by sprinkling them over the surface. The beds were then covered with straw to protect the seeds from the heat of the mid day sun, because the excessive heat of the sun affects the germinating power of the seeds. The seed-beds were then watered very sparingly till the seeds germinated. The water was poured along the borders of the beds so carefully and gently that its motion might not disturb the fixture of the seeds. The seeds germinated in between five or six days, then the covering straw was removed. The seedlings were fit for transplanting when they had four or five small leaves, or when their stocks had attained sufficient vigor to stand against any fall of rain when transplanted. Before they are pulled up from the beds the main thing that requires to be attended to is to divide the prepared field into small plots separated by ridges. Each plot so formed is twenty feet long and-three-and-a-half wide. After the formation of the plots they are stirred, loosened, and levelled, and then marked out in rows at a regular distance, one half foot from one another, in those rows small holes were dug at a distance of one half foot from one another to insert the seedlings; after this was done the seedlings are pulled up out of the muddy soil from the seed-beds. The day before they are pulled up care is taken to keep the soil of the beds sufficiently moistened, so as to allow of the seedlings being pulled up easily. The seedlings are carefully taken up by the hand without shaking off the earth adhering to the roots. Particular care is taken that the roots be not in any way injured. They are then placed in baskets and conveyed to the prepared field, where they are inserted in the holes. The time chosen for planting is the evening. The roots with their adherent earth are carefully and completely buried up to the bottom of the stem. The holes are moistened before setting the plants; a single plant is placed in each hole with the exception of 100 holes, wherein double plants are inserted. The object of this is to replace such of the single plants as may have withered and perished, should, however, none of them perish, one out of each of the two plants inserted in the reserved 100 holes is pulled up at the time of first weeding and thrown away.

Now great attention to watering the plants is required. They must be watered regularly every alternate day, care being taken that they are watered sufficiently. The hollows found close to the plants occasioned by the action of the watering are carefully filled up.

Now the soil is hoed about the plants very carefully for the purpose of eradicating weeds; after the removal of the weeds the soil so hoed is exposed to the influence of the sun and then the plants are not to be watered for two or three days. The holes are then repaired and the plants are watered again. Ten days subsequent to this operation a second weeding is attended to.

From the day of planting the seedlings up to the date of second weeding, embracing a period of 25 days, the plants are watered from pots. On the twenty-first day small hillocks of earth are formed by drawing the soil around the plants, and then they are watered from a well by means of a picottah. The water is allowed to flow by passing through small channels cut through the fields. The water so used is somewhat brackish. It is a matter of paramount importance that great regularity and punctuality should be observed in watering.

When the plants grow vigorously they are liable to the attack of insects; sometimes the insects make sad havoc with the crops. The crops are examined every morning, and the insects found on them picked off and killed. The insects retire from their lodgement on the plants when the day becomes sunny, and lurk about out of sight.

Sixty days after the transplantation, the plants begin to throw flower shoots. These shoots are nipped off, so as to prevent flowering; were it not done, they would draw from the plants the sap that is essential to nutrition. The stems that spring from the main stalk are also pruned off a few plants are left for seeds; the heads of these are allowed to shoot to their full length.

The plants grow to about 25 inches in height, and the leaves to about 21 inches long and 8 wide.

The plants are known to be ready for cutting by exhibiting a hairy clammy exudation which forms over the leaves, giving them yellow blotches or spotted appearance. If the leaf be then tasted, it will be found to have a mixed sour and bitter flavour."

NOTICE TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

REPLIES TO CORRESPONDENTS.

THE "KIKAR" TREE; MANGO GRAFTS; RED ANTS IN COFFEE; YIELD OF COCONUTS; CORUNDUM.

TO THE EDITOR.

SIR,—A press of work prevented me from replying to information asked for in your issues for November and December 1880, so I take this opportunity of replying to those as well as to that contained in your current issue. I do this in one letter to save space in your journal, and to relieve myself of the necessity of writing several letters.

In reply to the request contained in last November's issue from W. S. Howland, Mundapasalai, South India, I write to say that the botanical name of the Kikar tree is *Accacia Arabia*, known popularly in English as Babool, and in Tamil as *Kuroom Valum*. This tree grows almost throughout South India, and your correspondent will have no difficulty in procuring the seeds in his own, the Madura district, by its Tamil name; should any difficulty arise, and your correspondent would care to apply to me direct, I wi[illegible] have the seeds collected and sent to him. The Babool is a very [illegible] tree; its gum is used as a substitute for Gum Arabic; its bark is not only used in native medicine, but also for distilling the country arrack and for tanning purposes. Its wood is strong and useful for many household purposes, whilst its seed pods are always sought for by shepherds, to feed their sheep and goats with. The Babool grows rapidly into a handsome tree, when cared for, but its drawback is that it is very thorny. There is another tree, also known as the Kikar, the *Accacia Loncophlaa* or *Veloaylum* (Tamil,) which resembles it much, except that the general appearance of the tree is much lighter; it is put to all the same uses as the *Kuroom Valum* and also abounds in the south.

In reply to your correspondent LANGRA, in the same issue, I write to say that there are a large variety of graft mangoes to be had in the Madras Presidency, and some very fine fruits are produced about Madras, North Arcot, Salem, Bangalore, and other places, under a variety of names—such as Peter, Pussund, Dil Pussund, &c. Mango grafts are prepared for sale at most of these stations; at Madras eight annas is asked for each plant, in North Arcot four annas, and at Salem as much as two rupees for each is asked, I believe. In Bangalore a gentleman has gone in for an extensive graft mango plantation which was valued at some lakhs of rupees, and not long ago one-half share was in the market for sale.

With regard to the question about red-ants in coffee, in your issue of December last, I fancy the red-ant referred to there is what is known among naturalists as the *Formica Smaragdina*. I would suggest that old flannel or woollen cloth rags saturated with carbolic acid oil (1 to 20 parts) be suspended about the infested trees. I would also pour some of the carbolic oil into their leafy nests, and in the course of a few days they will vanish from the locality. Your correspondent states that he has tried carbolic acid, &c., already; but I would ask him to try it again, after the manner I have suggested, for a week or ten days, and report the result.

With reference to the question put by your correspondent, M. Hammlell, I have counted over one hundred coconuts on a single spadix (bunch); such bunches were exhibited at the Agricultural Show at Chingleput some years ago, and I have also seen them at the Madras Agri-Horticultural Show, but they did not attract attention and were looked upon as curiosities. As a fact, in a well tended cocoanut plantation, the average is from 100 to 150 nuts per annum per tree. The natives value the produce of a coconut tree at one rupee per annum, and at this rate they are contracted for at Madras and elsewhere, either for the sake of the nut or for drawing toddy. Toddy drawing always pays best, though the trees suffer from exhaustion, where they are not freely irrigated. A cocoanut tree is believed to throw out a flower spathe every month, or twelve in the course of the year.

In your current issue for January, a writer inquires about Corundum. This mineral is supposed to be the hardest known next to the diamond

It is met with in most parts of India, as well as in parts of Europe, and is chiefly used for polishing gems, marbles, and metals. In the Madras Presidency it is used as grind and whet-stones, hones, rag-stones for sharpening knives and other cutting implements. In Tamil it is known as *Curungi Kullov*, and in Hindustani *Curonj*. It is in general use among sepoys for cleaning and polishing their arms, &c. There are several varieties of Corundum extant; one of these is known as emery, and is extensively used in Europe for grinding and polishing metals, glass, &c. Picked stones will fetch from £10 to £20 the ton in Europe, but the natives sell it by measure. For further particulars I would refer your correspondent to Balfour's Cyclopædia, 2nd Edition, Vol. 1, article Corundum, which gives a full and exhaustive account of this mineral; it is too long to extract here.

JOHN SHORTT.

The Retreat, Ercaud 15th January 1881.

ABOUT PAPER FIBRES.

TO THE EDITOR.

SIR,—In my previous letters I have referred to three classes of fibrous plants available for paper material, *viz.*, the grasses or sedges:—those produced from what are termed herbaceous plants, of the nature of hemp, flax, and jute, and those derived from siliaceous or bromiliaceous plants such as aloe, yucca, pine-apple, and the Musa tribe (Plantains). I now desire to direct attention to another class of fibrous products, termed bark fibres, some of which offer a fair prospect of being profitably utilised for paper-making material. This, however, will depend on the assurance of a continuous and reliable supply in quantities sufficient to make them a recognised staple in the market. Having been enabled to test some of this class, samples of which are now deposited in the museum at the Royal Botanical Gardens, at Kew, I give the results of my experiments abstracted from the "*Official Report*, 1879."

"*Indian Forest Fibres.*—The important collection of Indian forest "products transmitted to Kew by the Indian Forest Department "included an extensive series of bark fibres; specimens of these were "placed in the hands of Mr. Routledge of the Ford Works, Sunderland, "to whom Kew is under constant obligation for information and "assistance in connection with the paper manufacture. He was good "enough to test them all as regards their yield when converted "into rough (paper) stock, and he has furnished us with the follow-"ing report":—

	Green yield.	Bleached.
"1. *Banhinia Vahlii*; excellent strong fibre hemp character and tough	60 per cent.	54 7 per cent.
"2. *Bombax malabarica*; coarse, harsh, woody; tender and short, bleached ...	48 "	37·5 "
"3. *Butea frondosa*; very coarse and woody; rotten and short, bleached	56·25 "	37·5 "
"4. *Careya arborea*; coarse, rather harsh and woody; somewhat tender, bleached ...	47 "	45 3 "
"5. *Eriolæna Hookeriana*; very strong but harsh; better felting property than 8 to 12	50 "	42·8 "
"6. *Ficus Bengalensis*; fairly strong and fibrous; rather tender, bleached ...	61 "	54·7 "
"7. *Ficus infectoria*; good, strong, and fibrous; fair quality, bleached	51·7 "	51·5 "
"8. *Grewia tiliæfolia*; strong, harsh, wiry, hard; same bleached	50 "	43·7 "
"9. *Helicteres Isora*; very strong, green; better than 8 and 10 to 12, bleached ...	68·8 "	61 "
"10. *Sterculia colorata*; similar to 8 and 11, harsh and wiry	60·7 "	59 "
"11. *Sterculia urens*; similar to 7, rather better	59 8 "	47 "
"12. *Sterculia villosa*; similar to 8, 10, and 11...	60 "	51·5 "

"Of these fibres No. 1 is decidedly best, possessing the characteristic "of strong linen rags, *i.e.*, of coarse flax and hemp; the raw bark is "worth £7 to £8, possibly £9, per ton; the bleached stock £20 to £22.

"No. 7 is the next best bark, worth £6 to £7 per ton raw. None of "the others are of much value for white papers, excepting perhaps "Nos. 5 and 9; say £5 to £7 for No. 5, and £5 to £6 for No. 9. It "would, however, be necessary to make a practical working trial, that "is, to make paper from all of them (excepting No. 1) before pro-"nouncing positively as to value: No. 1, I believe fully worth what I "have appraised it at.

"All of these raw barks required a very large dose of bleach to bring "them to even the low colour they are. No doubt opening them out "by willowing or teasing them, both before and after boiling, would "materially improve them. I do not consider, with the exception of "Nos. 1 and 7, it would pay to import them from India.

"*Broussonetia papyrifera*. The bark of the well-known paper mul-"berry supplies the material from which the *Tappa cloth* of Polynesia "and the bulk of the paper of Japan and China are manufactured. The "Japanese cultivate the plant very much in the same way as we grow "Osiers, and they use only the young shoots for the manufacture of "paper. A sample of the bark which came into the hands of Mr. Rout-"ledge is stated by him to be 'nearly if not quite the best fibre I have "seen' . . . 'I must admit it is even superior to bamboo" . . . . "It "requires very little chemicals, and gives an excellent yield—62·5 per "cent in the grey *i.e.*, merely boiled; and 58 per cent bleached."

It may be well to add that the employment of the native *Dhenkee*, as recommended by Dr. Royle, with the addition perhaps of soaking in hot-water, and without recourse to the use of chemicals, may materially reduce the bulk of this class of bark fibres; otherwise, from their bulk as collected, the cost of carriage and frieght would (with some exceptions) be almost prohibitive; the presence also of the rough and, generally speaking, dark colored outer portion of the bark which is useful for paper-making would deteriorate their value. The employment therefore of the *Dhenkee* or some similar appliance to reduce them into the condition of a rough stock would be desirable if not necessary.

Some of the "Barks" of the "*Lace Bark*" tribe—the "*Daphne Cannabina*," or "*D. Lagetta*" common in Nepaul, the "*Broussonetia*" and others of the "*Morus*" or mulberry tribe—would, I feel assured, pay well for cultivation, and as the clean bark merely requiring stripping from the season shoots, with the outer skin removed, would be readily prepared for, and would fetch good value as paper material, there is every inducement to at least "prospect" in this direction. I may add that the most favorable localities for such an industry, appear to be the tea districts of India—Assam, Cachar, Nepaul, and up to Kumaon.

It may be well for me to conclude with a few remarks, pertinent to the general issue or bearing of Mr. Liotard's Memorandum. It unfortunately happens that paper-makers as a rule, know very little about botany, and it is equally true that botanists and their representatives, the reporters in Mr. Liotard's Blue-book, know but little about the technical requirements of paper-making; the consequence is that great confusion reigns, and I am afraid is likely to continue while making clear, and correctly defining, what really is the *raw material* the paper-maker desires. There is all the difference imaginable between a *fibrous plant*, and the *fibre* produced from such plant. The paper-maker knows but little, and probably cares less about the fibrous plant, but he knows well when he sees the "*fibre*" produced, and will use it, provided he can obtain it at reasonable cost (as compared with existing material) and of a quality suited to his requirements.

It is extremely improbable, however, that any English paper-maker will embark capital in so distant a country as India, for the collection and preparation of the "*fibre*" from plants of which, as remarked, he knows little or nothing, or of the remote country where they grow. I think, therefore, it is obvious that some intervention must come between the botanist and the paper-maker; and this intervention, naturally, indeed I must add necessarily, must be carried out by the native collector or cultivator, assisted by the Government or in co-operation with merchants and others knowing and having commercial relations with India itself. It is to this class therefore that my remarks are specially addressed.

THOS. ROUTLEDGE.

Claxheugh, Sunderland, 15th December 1880.

SUGAR FROM *SORGHUM*.

TO THE EDITOR.

SIR,—Some seeds of the *Sorghum Saccharatum* and *Sorghum Kaffrarium* were sown in Burdwan, in the early part of October 1880. The result was very satisfactory. They did not require any irrigation at all, and they grew very luxuriantly. Canes weighing 20lbs were crushed, from which 8lbs of juice were obtained, and the leaves were given to the cattle. Four pounds of the above juice were at first boiled, into which some quicklime was added and the impurities were skimmed off. The juice was reduced to such a state by boiling, that it was granulated on cooling; 1lb of the granulated syrup was thus obtained from 4lbs of juice. The other 4lbs of the juice were afterwards boiled from which—with the addition of some diluted milk, in order to separate the impurities, which were skimmed off as soon as they formed on the surface—I have succeeded in obtaining 1lb of raw sugar (*goor*). Being a small quantity, no crystallized sugar has been manufactured therefrom here.

The result of the above trial has led me to the conclusion that diluted milk, *i.e.*, milk mixed with water, should be added, instead of quicklime or lime water; and that sugar in sufficient quantity and of first-rate quality is obtainable from *Sorghum*, and that it will compare favourably with the best product from sugarcane grown in the most favourable localities.

The great point claimed in the cultivation of *Sorghums*, is that they can be grown in Northern India, by sowing from May to September, without the aid of irrigation at all, and that three cuttings are obtainable per year. I have obtained from 8 to 10 tons of their canes per acre fit for crushing, at a single cutting, in Burdwan. I have also found that the *Sorghum* crop requires no such care as the sugarcane plant, does; as to tie or roll up from time to time the growing stalks with their own leaves.

I experienced no difficulty in the purification of the syrup, and I should also state that no special arrangements for precipitating the impurities of the juice were necessary. I have no proper crushing mill, no evaporating range, but with a simple mill, made of wood, and a simple earthen boiler, and in another case an iron vessel; and with the addition from time to time of some diluted milk, in order to separate the impurities, which were skimmed off as soon as they formed on the surface,—I have succeeded in obtaining the required sugar. The result of the above trial, although it was on a very small scale, induces me to make a further experiment on a large scale, in November next, and I shall be glad to write you the results. I am informed that 45 millions of acres are now cultivated with *Sorghum* in the United States of America, and that 2,000lbs. of sugar, per acre, besides molasses, is stated as being an easily obtainable outturn.

I had occasion to write to the Superintendent, Government Farms, Madras, the result of the above trials, on the 1st instant. In his letter No. C 16, dated 14th instant, Mr. Robertson replied as follows:—"I read your letter of the 1st with great interest. The result is very satisfactory. I hope that you will be induced thereby to make an experiment on a large scale, and favor me with the results for publication. There can be no doubt that the *Sorghum* crop will in time in this country, as in America, become an important sugar-yielding crop."

BONOMALY KOONDOO.

Burdwan, 20th January 1881.

NOTE.—We shall be glad to hear the result of our correspondent's further experiments. A few remarks on the *Sorghums* will be found in our editorial columns. ED., *I. A.*

PLOUGHS.

TO THE EDITOR.

SIR,—Under the head of Editorial Notes at p. 6 of the *Indian Agriculturist* of 1st January, your Burdwan correspondent is advised to give a fair trial to the improved native ploughs, of which you state, there are several in the market at present. People in this part of India, at least, will, I am sure, quite agree with you in considering that what is wanted in India is an improvement of the ordinary country plough. The native ploughs you refer to are, it is presumed, such an improvement. If they are not far more costly than the ordinary country ploughs, and can, when necessary, be easily repaired, I would recommend, on behalf of the agriculturists of this presidency, and for their benefit, that a complete description of each of the several kinds of native ploughs in question be published in your valuab'e journal, notifying their prices, the advantages to be derived from each, where they can be obtained, how long they will last without needing repair, at what cost they may be repaired, whether for repairing them professional skill such as may not be easily procured will be required, and so on. A full description, as suggested above, will, it is hoped, go a great way in improving the system of farming now in force in this presidency. The interest I take in the welfare of my countrymen wedded to agriculture, must serve as my apology for troubling you with this letter. Wishing for an ever-increasing circulation to your invaluable organ.—

R. S.

NOTE.—We shall consider our correspondent's suggestion. But we have on various occasions noticed editorially most, if not all, of the principal new ploughs, as our constant readers must be aware.—ED., *I. A.*

TASAR SILKWORMS.

TO THE EDITOR.

SIR,—Will you kindly let me know where I can purchase a small quantity of Tasar Silkworm eggs. If you or any of you readers can give me this information, I shall feel obliged.

X. Y. Z.

NOTE.—There is no market in India for the above. Some private collector will perhaps oblige our correspondent.—ED., *I. A.*

FODDER GRASSES.

(To the Editor of the Ceylon Observer.)

DEAR SIR,—The complete failure in growing such a thing as prickly comfrey, induced a neighbour and myself to experiment with several varieties of European grass: we cannot say with much success, as the difficulty we had to contend with was bad lay of land; but whenever there was little *wash*, the result was highly satisfactory. Italian Rye-grass stands foremost, but does not equal teosinte, the Mexican grass, for quantity. This latter is not of course a European variety, but a tropical grass; hence the success in growing it even in very low elevations. One reason why cattle readily eat the thick stalks, be they ever so dry, is, that the cobs containing the *seed* adhere to the stalks and the seed is like so much corn, very palatable. The fowls fatten on them, and for a while it was a puzzle to me to account for their straying into the teosinte grass field so persistently. I do not advocate the neglecting of guinea grass, but those who really desire to obtain, rich milk and so, good butter, should pay a little attention to *variety* of food, which is so essential to cattle. This can only be done by having at least four to five varieties of grass, such as Mauritius, Guinea, Teosinte, and Rye-grass. I had less cattle here ailing this year than I have had for several years past, and the only way I can account for it, is the change in their food, and to *grooming*—a thing totally *forgotten* in this Island, and yet we expect our cattle to be in as prime condition as those we see at a European show or fair.

The grass fields must be up only twice a year, shortly before the rains, and old drains should then be closed and *new* ones made. Very little manure is needed. Many fields of grass I have seen with manure lying perfectly inert on the surface. A digging fork and even a mamoty applied at a trifling cost would have astonished the superintendent in results. Teosinte grass seed must not be sown thickly and should be cropped early; a pound of seed would do for 1½ acres.

STOCK.

II.

DEAR SIR,—Reading "Stock's" letter on fodder grasses has induced me to pen a few lines on the same subject.

Prickly comfrey grows well with us; Australian cattle and horses like it well, but I feel bound to say I do not advise any one who has it, to feed cows that are in calf with it. Clover, lucerne, and some other English grasses grow well, but none of them will pay; at least this is my experience. "Teosinte" I have tried, two lots of seed, first from a Colombo firm; none grew: next from the Peradeniya Gardens: out of this lot I think there are 8 or 10 plants, so I can't say much for it as yet. Buffalo grass grows well, but is more fit for grazing purposes; having a trailing habit, it is very suitable for binding loose earth or for the slopes of an embankment. I will now mention the grasses that I find give the best results. "Water," *alias* Mauritius grass, for ravines and swampy land; "Guinea-grass", almost anywhere; "California Prairie" grass, on good or medium soils.

I quite agree with "Stock" that a variety of food is beneficial to cattle. "S." it at fault when he says in regard to *grooming* "a thing totally, I may say, forgotten in this Island." I have for years had all my better bred cattle groomed, and I know one or two others have told me they have had theirs done. As for manure, the more you dig into the ground round the roots, the larger the crop and the less refused by the cattle. Sickness.—I have had foot-and-mouth disease run through nearly the whole lot and in separate sheds, but I am thankful to say very little of any other. I believe in having the sheds thoroughly cleared every day and the drains all washed down; stall-fed cattle must have exercise every day.

Warwick, New Galway, 30th December 1880. C. W. I.

VALUE OF TEA AND CINCHONA PER ACRE.

(To the Editor South of India Observer.)

SIR,—With reference to your correspondent's query regarding the valuation of tea and cinchona, I give you the benefit of my experience. I should say, if the plants are well established and planted in 18in. pits that—

2 years old	...	...	...	200 per acre.
3 " "	...	...	...	250 do
4 " "	...	...	...	350 do
5 " "	...	...	...	400 do
An acre of Crown Bark.				
1 year old	...	...	...	500 per acre.
2 " "	...	...	...	600 do
3 " "	...	...	...	700 do
4 " "	...	...	...	800 do
5 " "	...	...	...	900 do
6 " "	...	...	...	1,000 do
7 " "	...	...	...	1,300 do
8 " "	...	...	...	1,800 do
9 " "	...	...	...	2,200 do
10 " "	...	...	...	2,500 do

It may be said tea has been at its lowest ebb lately: the consumption is rapidly increasing and by last advices, prices are improving.

The price of bark is not likely to fall for years to come; the Condaminea or Crown Bark, when it yields Renewed Bark, increases in value, the yields of an acre being equal to 300lbs. at 8 shillings a pound.

I see by the Australian papers that Indian teas are now very greatly in demand all over that colony. The abominable rubbish hitherto imported from China and sold as *tea*, has been quite superseded by Indian teas, which, from their purity and excellence, are preferred to any other, and fetch very high prices in the Australian market.

OLD PLANTER.

CINCHONA SUPPLY AND DEMAND.

(To the Editor of the Ceylon Times)

SIR,—Refering to your remarks regarding the number of cinchona plants in Ceylon, Mulhall gives the number as 50 millions of young plants; against 3,000,000 trees over thirty feet high in the Neilgherries. Thus, the Neilgerry plantations alone can throw into the market enough bark to supply the market of the whole world for two years.

STATIST.

OXIDISING CINCHONA.

(*To the Editor of the Ceylon Times.*)

SIR,—I notice that after eradicating leaf disease, the scientists are contemplating taking cinchona in hand with a view to the conversion of the inferior alkaloids into those of a higher value. Whether this can be done or not is a matter which is beyond the range of ordinary criticism, and I for one should not think of calling in question the power of any chemists, knowing as we do what science has done for the world. But I have a word to offer on another point, and that is the economical outlook. I notice in a local paper a remark to the effect that should these experiments prove only partly successful, they cannot fail to exercise a very marked influence on the future of cinchona cultivation and the quinine trade. No doubt they will. But quadrupling the yield of the higher price alkaloid, chemists will at once reduce its market value. *Succirubra* will be placed on a par with *ledgeriana*, and quinine will decline to a rupee a pound. These are amongst the inevitable results. Whether they are calculated to advantage, cinchona growers in the long run, remains to be seen, there may well be doubts on the subject.

Fort, Jan. 5th, 1881. QUERCUS.

CROTON SEED AND OIL.

(*To the Editor of the Ceylon Observer.*)

DEAR SIR,—Mr. Holloway's letter, with my note on the croton oil tree (*Croton Tiglium*), which appeared in your issue of the 15th instant, escaped my notice at the time. The price quoted by me (*5s.* per lb.) referred of course to the croton oil of commerce, and not to the unmanufactured seeds. There can be little doubt, however, that the seed could be produced in Ceylon, at a cost which would leave a handsome profit to the grower, and a few notes on the tree may be of some interest.

It is a native of Ceylon and India, very common, I am told, in the Maturata district, and is met with in the neighbourhood of Kandy. The seeds are in common use with our native doctors as a purgative, and are known by the Tamils as *nervalam kottai*, and by the Singhalese as *jayapala*. The fruit or seed capsule—of the dimensions of a large coffee cherry—contains three seeds, which are very similar in size and appearance to those of the castor oil plant, another representative of that interesting family the *Euphorbiaceæ*; and here we have presented to us one of the many anomalies to be found in this wonderfully-formed group of the vegetable kingdom. The castor oil plant (*Ricinus communis*), yielding one of the best and safest of all purgatives when purified, we find side by side with the croton oil tree which possesses the most violently acrid poisonous principle, one grain of the powder or one drop of the oil being a sufficient dose for an adult, while a single seed has been known to kill a man.

The croton oil plant will no doubt form a good shade or boundary tree of rapid growth, about 25 feet in height, and bearing a great weight of highly oleagenous seeds, but possessing a soft timber of little or no value. Being a native of the Island, it will be hardy and independent and like most of its congeners (*e.g.*, the *manihots*) a fast grower. Still it is difficult to imagine that there can ever be any great consumption of the oil, and from the very poisonous nature of the plant, it would not be a desirable cultivation to go in for. Both croton seed and oil are now exported in considerable quantities from Madras and Bombay, and the oil is said to be expressed and prepared in the same way as castor oil, except that it is strained instead of being boiled.

A. WHYTE.

P.S.—I find I am all behind the age again: so much for not seeing the papers. "Caution's" letter in the *Observer* of 20th instant, has just been brought to my notice. His quotation of *3d.* to *9d.* per lb. of seed is no doubt correct, and I see by a *wholesale druggist's* circular, received last mail, that oil is quoted at 5 per lb. as stated before. What the London market figure may be, I cannot say. The seed is said to yield 50 per cent of oil, and judging from the size of the trees they ought to be planted about 10 × 10 ft. If, therefore, Mr. Holloway can furnish us with the average yield of clean seed per tree, there will be some data to work on, in arriving at an approximate return of oil per acre.

PANCHGANI AS A FIELD FOR PLANTERS.

(*To the Editor of the Times of India.*)

SIR,—I will feel myself under obligations to your widely circulated paper if allowed to make the following suggestion. Panchgani has a very fertile soil. It is a soil in which coffee flourishes and tea might easily be produced in the valleys where the river Krishna would supply the necessary water. The only difficulty in starting a coffee plantation would be the scarcity of water, but with a little expense water could be supplied. From Lingmara seven miles away, water could be brought down in pipes. Lingmara is higher than Panchgani, and water finding its own level could easily be brought to the desired place. If a private individual were to make the undertaking he might sell some of the water to the residents, many of whom would be likely to use it for gardens, having enough for household purposes. There is no doubt that the returns of a plantation would yield an immense profit. An enterprising capitalist setting up would find it to be a profitable undertaking.

COFFEE.

The Indian Agriculturist.

CALCUTTA, FEBRUARY 1, 1881.

THE TEA INDUSTRY.

THE tea industry is passing through a crisis. In 1865 to 1867 a similar crisis ruined all save strong companies which had good financial support. At that time even the most unfortunate shareholder, if he knew any thing of the industry, knew that it was a perfectly safe one, but that it was impossible for a company in debt to tide over the difficulty; and so, many companies and private concerns went to the wall, and gardens which had cost perhaps a couple of lakhs of rupees, were thrown upon the market and found purchasers at sums varying from one to ten per cent of their cost. Then the cause was sheer recklessness; now the crisis has been brought about by totally different causes. Then, to a large extent, shareholders and managing agents were not perhaps so much to blame; as they were feeling their way in a new path, and were perfectly ignorant of many details of which they are now cognisant. Then they had no data to go upon. Now they have had twenty years' experience, and hence there is less excuse for the difficulties they have brought upon themselves. The present crisis may be attributed to three causes, all of which ought to have been foreseen and avoided. The first which we shall notice is—bad financial and general management. The principle of remunerating managing agents is financially unsound. These gentlemen have practically the complete control of the tea concerns; as a rule, they have very little work and no responsibility, and they are paid sometimes by a commission on the gross outturn of the properties in their charge, without regard to whether profit has been made or loss sustained; hence we see the anomaly of these agents getting more by way of commission and salary than the entire body of shareholders get amongst them. The latter, it must be remembered, have invested their money and run all the risks that exist. We are far from suggesting that managing agents should not be paid for their work; we only object to the present mode of paying them. It is absurd to see a company, struggling in the meshes of impecuniosity, paying handsome salaries and allowances to agents who have absolutely no risk, and who can usually carry on the work of a number of gardens with the help of an extra native assistant or so. It may be said that the agent frequently advances large sums of money to gardens, and thereby incurs a responsibility; we think we are right when we say that the agent only advances cash in the same way that any other money-lender would, on good security. He has, usually, the coming crop as his security, and as he knows exactly how things are going on, he is in a peculiarly favourable position, to see to the safety of his advance. We are of opinion however, that all advances should be raised otherwise than from agents, and if the ordinary sources from which cash is available should fail, a sufficient sum could usually be raised from individual shareholders, or even, as an extreme measure, by the creation of a small amount of fresh stock, which being looked upon as a debenture-stock, could be redeemed and cancelled when the company found itself in funds. Besides, every well-conducted tea concern should have a special fund for working-expenses,—a fund sufficient to carry on operations until returns began to come in. The only way by which a concern heavily in debt on account of these advances, can recover itself, is by utilizing all profits by way of reducing that debt. This is difficult where shareholders clamour for dividends, but it is false economy to insist on receiving a small dividend, when the property is burdened with a heavy debt bearing an interest charge, at the rate of 8, 10, or perhaps 12 per cent. Pay off that incubus, allow a sufficient amount

of cash to accumulate for working expenses, and the whole concern will then, for the first time perhaps, get fair play.

Then we come to the second cause of this state of affairs. Indian tea if sent to the London market as that market requires it, will always command a fair price; perhaps not the fancy prices of 20 or 25 years ago, but still, prices sufficient to pay all concerned handsomely. To take advantage of this, we must, however, watch the market, with a view to prevent flooding it; and this is exactly what we have not done. Fancying that the high prices of former years would continue, and foolishly shutting our eyes to the possibility of the demand failing to keep pace with the supply, we have gone on extending our cultivation, and consequently increasing our exports to the London market, till stocks there, are three times as heavy as they ought to be. The mischief is done, and if the proprietors are wise they will resolutely stop extension until the consumption at home shews signs of overtaking supply, when prices may be expected to recover somewhat. In the meantime stocks can be relieved, and the market improved by our ceasing to flood it with a large quantity of low class teas. We should make as little of these as possible, confining our attention to high class teas alone, and only making such low class qualities as are unavoidable. Even these latter we should endeavour to dispose of locally, and thus we should relieve stocks at home, and keep up the general average quality of the teas we offer in Mincing-lane. Owing to this average being high, we shall get higher prices, and shall not, therefore, lose by the change. The market of great Britain just now, however, is showing unmistakeable symptoms of having passed the acme of the crisis, and consumption has overtaken demand. Should this prove permanent, which there is every reason to expect, prices will rise, and better times for the shareholder present themselves.

The third cause of the late abnormal depression is, in our opinion, the quality of the tea we make. We do not mean that our classes are not up to a fair standard; we refer to the suicidal mania for pungent tea. For trade reasons, and not because the public want it, a demand exists for this pungent rasping tea, and in obedience to the fiat of the brokers, we have pandered to the morbid taste, and have had the reward we deserve. We have gone on manufacturing a manifestly inferior article, because it was wanted by the middlemen of the trade for purposes of adulteration. We should have set our faces against such an iniquity; but—for profit, as we foolishly imagined—we encouraged the deceit. The mixture thus made has almost invariably been sold as pure Indian tea, and—as only about one-sixth to one-fourth was Indian, and *that* the badly made rasping tea,—the good name of Indian tea suffered, and prices fell. If we ask a manager to make us a sample of really good drinkable tea, it will never enter into his head to under-ferment it. He will submit it to sufficient fermentation, and will turn out a delicate sample, such a sample as would represent all Indian teas if the broker's interest were not consulted before that of the shareholder. If we wish our tea to take its proper place in the world's markets, we must return to the proper way of making it. It is a strange thing that the proverbial ingenuity of the Chinese did not enable them to find out in all these centuries, that rasping tea was the best. It was left for us to find out this fact, and to engage in the suicidal trade until we have brought the industry to the very verge of bankruptcy.

MR. MARKHAM ON PERUVIAN BARKS.

We are glad to find that Mr. Markham has fulfilled his promise of giving a popular history of the introduction and cultivation of the Peruvian barks into India.* Although Mr. Markham in his "Travels in Peru and India" gave very fully the history, search for, and introduction into India of these plants up to 1862, yet in this later work we have so much only of it repeated and newer matter added as to give a completeness to the narrative, and the whole history is brought down to the present date, in order, as he says, that the whole question "should be familiar to Englishmen and the educated classes of India."

The world has long been indebted to the mountainous regions of the Andes for the barks from which the inestimable quinine is prepared, and the great and increasing demand for it renders a constant and never-failing supply imperative. The story of the reckless destruction of cinchona trees has often been told, and serious fears, far from being unfounded, were entertained that some day the supply of Peruvian bark from South America would fail us. The veteran Indian Botanist, Dr. Royle, insisted on the necessity of the introduction of these trees into India; but the Government took no action. To Mr. Henry Deedes is due the credit of first bringing the subject to Mr. Markham's notice. The latter says that after considering that, except in normal years of cholera, fever is by far the most prolific cause of death,—far more than all other diseases and accidents put together, amounting in fact to one and-a-half million a year—he formed the resolve to endeavour to place within the reach of even the poorest native, the best known alleviation and cure for fever, namely, Peruvian bark, and this in its cheapest and most effective form. The first step to carry out this resolve was the introduction of the quinine trees into India, and this task, as all India knows, has been most nobly and successfully carried out. The difficulties of the task thus undertaken are by no means to be underrated. There was the transit of seeds, from almost inaccessible and most hostile countries, to India; to convert those wild plants into cultivated ones, and to endeavour not only to keep up the standard of excellence but even to improve; to study their native climate, soil, and surrounding physical aspects; to compare these data in finding a fitting home for them in India; and lastly, to ascertain the best and cheapest available form for their use in medicine.

The history of the Peruvian bark trees is now pretty generally known. Of course Mr. Markham still fights with an earnestness worthy of the best days of the old Spanish chivalry, for the word *Chinchona*. This should be really the correct spelling of the genus of plants yielding Peruvian barks. It was named in honor of the Countess of Chinchona who accompanied her husband to Peru on his appointment as Viceroy of that province. During her sojourn in Peru (in 1638), this lady was ill with intermittent fever and was cured by the use of Peruvian bark. On her return to Spain she made the virtues of this bark known, and Linnaeus named the genus after her, but spelt it *Cinchona*—an unfortunate mistake truly, but too late now to be remedied.

The description given of the different bark regions—crown, red, Colombian, grey, and calisaya,—are all good, and will be read with profit and interest; and the strenuous and long-continued efforts to represent all these trees in India show an amount of perseverance rarely equalled and still more rarely crowned with success. Mr. Markham, although the formation, elaboration, and detail work is clearly due to himself, does not forget to pay every tribute to those who were his co-workers, and acted under his orders. These are Mr. Weir, Dr. Spruce (the veteran Botanist), Mr. Pritchett, and Mr. Cross—the latter having made five or six journeys, his last one being that for obtaining seeds of the soft Colombian bark trees. Nor is Mr. Ledger forgotten. He, although not under Mr. Markham's orders, yet did splendid service in the obtaining of the variety of *Cinchona calisaya* named by Mr. Howard variety *Ledgeriana*, yielding as it does the magnificent amount of 9 97 per cent of quinine. These men all worked with a zeal and energy beyond all praise. They were paid bare remuneration for their services, in the hope and expectation that should the enterprise prove successful better acknowledgment awaited them. They went with their lives in their hands, and the privations some of them underwent have made them old and decrepit "before their time." But although Mr. Markham has long and earnestly pleaded their cause —not to shew charity, but to mete out justice, and not out of the pockets of the already overburdened tax-payers of India, but out of the splendid net profits resulting from their labours—a deaf ear has been turned to all such appeals. Can we wonder that Mr. Markham speaks of his indignation at such injustice in the "treatment "of those gallant men who, amidst perils and hardships of no "ordinary kind, performed the work by which India will be so "largely benefited. Those who did the work have not received

* "*Peruvian Barks: A Popular Account of the Introduction of Cinchona Cultivation into British India.*" By Clements R. Markham C B., F.R.S., 1860-1880, with Maps and Illustrations, pp. xxxiii; 550, London: John Murray.

"fair recompense for most valuable services. But the work itself "has conferred an inestimable blessing on the people of India, "whilst it has at the same time become a remunerative public "undertaking." But alas! everything for the good of India must give way to a "Scientific Frontier" and such like chimeras.

After obtaining the seeds and plants, the great difficulty was the selection of the site for the first plantation in India. Ootacamund was selected, and here Mr. Markham had the benefit of the services of the late Mr. McIvor, whom he styles "the ablest arboriculturist in India," and to whose care he "gladly and with perfect confidence" committed this trial cultivation. Most happily for the enterprise, this perfect accord never wavered. Mr. McIvor's success was indeed wonderful. Of the seeds committed to his charge 60 to 90 per cent germinated in burnt earth with a temperature of 60° by night and 75° by day. Latterly he even obtained better results with a temperature of 55° and 65°, giving the seeds a very sandy soil with an uniform medium state of moisture, and from his experiments he found that from *eyes* he could raise 8 to 1 as against seedlings. Happily he steered clear of the almost fatal and costly mistakes committed at first by the Dutch in Java: he found that for the health of the plant and the development of the greatest amount of alkaloid, plenty of light and air were necessary, and that dense shade was baneful. In planting out he found that a rich, loamy, rough, and very open soil was necessary, and a very slight shade at first was all that was requisite. One of the good results of cultivation soon became apparent—a sample of grey bark collected in its native habitat yielded 1·8 per cent, whilst plants raised from seeds and obtained from this very same tree yielded 7·5 per cent; and this is only one instance out of many.

Some remarks are given on the best method of harvesting the bark. "Coppicing", as Mr. Markham says, presents the most obvious method. Mr. McIvor's method of removing portions of the bark and then "mossing" over, to allow of fresh bark being formed, he thinks much too delicate an operation for other than "skilled" persons. Certainly the "renewed" or secondary bark is much richer, and it may be that its richness is at the expense of the rest of the plant. But as to the impracticability of the "mossing" by other than "skilled persons," we are by no means prepared to admit; it does not require a "skilled person" to cut off a strip of bark and then cover with moss the place from which it was removed, or, equally as efficacious, to daub over with a mixture of clay and cow-dung.

At Ootacamund hybridization seems to have first been noticed, and this may yet have a most important bearing on the improved results as obtained from the cinchonas under cultivation and proper selection, especially as analysed hybrids have yielded 10 to 12·2 per cent of total alkaloids, a result far in excess of that obtained from parental stocks. *Cinchona succirubra*, *C. officinalis*, and *C. calisaya* are greatly in proportion at Ootacamund, and these three species with their varieties will, we believe, be the staple growth of India; the first for special use in India itself, and the last two for export—they being the best suited for English manufacturers. Altogether this plantation has been a grand success, and all its net receipts are now profits. To none other does this satisfactory state of things owe its origin than to the late Mr. McIvor. No wonder then does Mr. Markham say respecting him:—"His monument consists in the marvellous "success of that cultivation. It is indestructible; and will last "for centuries. No man could desire to have a more noble "monument, nor one which could more fitly and permanently "record his labours." Since Mr. McIvor's death the gardens have been neglected and many valuable trees cut down, the object being to obtain large harvests without any view to the future. As to Government giving up the cultivation, now that private planters have taken the matter in hand, it would perhaps be premature. Good stocks of the best varieties must be kept up for distribution, many experiments have yet to be completed or undertaken; and this we fear it is beyond the power of private planters to initiate or to carry out.

Of the cultivation in other parts, that in Ceylon meets with its well deserved meed of praise, as do also the efforts (first resulting in failure and now crowned with success) in Java. As to Sikkim, only certain species are there found to repay cultivation; but the chief interest of this plantation arises from the fact that up to the present time the most successful attempt to carry out the last and keystone of Mr. Markham's programme—that of preparing a "cheap alkaloid"—has been made here.

Of the alkaloids found in Peruvian barks, quinine has for a long time been looked upon as the only one of value, and therefore barks containing the largest percentage have and still will realize the highest price. The other alkaloids have been almost looked upon as bye-products. The results of the Madras and other Medical Commissions, set on foot by Mr. Markham, have done much to place these other alkaloids on their proper bases and secure justice for them, and thus to help towards the solution of the problem. It is now generally agreed that in febrifugal value, quininidine is equal to quinine, cinchonidine slightly less efficacious, and that cinchonine is certainly less valuable, but that if administered in larger quantities secures the desired result. The isolation of quinine, existing as it does in much smaller percentages than is the case with the other alkaloids, is a costly and troublesome one, and a preparation containing a mixture of all the alkaloids seems to point a way out of the difficulty. Mr. Broughton's amorphous quinine met with some amount of favour from the medical profession, but the appointed committee adjudged it far too costly in its production. There are good grounds, however, for believing such judgment to have been premature, as a reasonable time had not been allowed to give the scheme a fair trial. Moreover, Mr. Broughton seems to have been unfortunately too much addicted to hostile criticism of the work of others, especially that of Mr. McIvor, whose concentration of energy on the work in hand he might well have emulated. Still, Mr. Broughton made a good beginning and cleared, to some extent, the way for future investigators.

The Sikkim plantation owes much to the warm interest taken in it by Mr. A. O. Hume, C.B., and we are in perfect accord with Mr. Markham in his pleading for a "Department of Agriculture," freed however from the many "extra duties outside the province of agriculture altogether." Mr. C. H. Wood, although holding the appointment of quinologist to these plantations for a short time only, yet has left his mark and has conclusively shown what *can* be done. He possessed the requisite qualifications in a high degree: not only was he a most accurate chemist, capable of the estimation of the thousandth of a grain, but he also had *practical* experience as to how to produce tons at *paying* prices. He found that he could turn out *Quinetum* (a most expressive term, coined by Dr. de Vrij, and meaning a collection of quinine alkaloids) at three rupees per lb., and at the rate of 10,000lbs., per annum. In 1879 there were actually sold 128,000 ozs., at 1 rupee per oz., and this, against 12 shillings per oz. for quinine, means a saving of over £60,000. The method of manufacture employed by Mr. Wood is simplicity itself, and requires no costly machinery. In all these experiments, chemistry has played a most important part, and before a species can be adjudged good or bad or fit for payable cultivation, it has to undergo this crucial test—the only test that can be applied—and every bark has to stand or fall in proportion as its alkaloidal yield is good or bad. The ascertaining of these points has entailed most laborious work, and to none is India more indebted in these respects than to Mr. John Eliot Howard, F.R.S. With the exception of a letter of thanks, what recognition has Mr. Howard received? Provincial Bumbledom (as a comic writer puts it) for obstructing a Royal party, with an address *written by some one else*, gets a knighthood, whereas such splendid and *unpaid* services as Mr. Howard has rendered are passed by! But at least we can say that India will not forget the debt of gratitude for his ready and valuable aid.

In remains only for us to say that the book has given us great pleasure. The appendices on *Caoutchouc*, &c., we must return to on a future occasion. The index and bibliography is everything one can desire, and we would wish the book in the hands of everyone interested in the subject. As to the author, all Mr. Markham has said in praise of his associates, belongs also to him in a yet greater degree. He formed a good and wise plan and carried it out against all obstacles, whether in the form of savages or red-tapists; which are the most to be dreaded we leave others to judge. Part of his latter successes must be attributed to his having official charge of the question at the India Office—a phase for inquirers for information, like a transformation scene is to children, long to be remembered with pleasure, though soon coming to an end.

ON GUTTA PERCHA.

ITS HISTORY, PREPARATION, AND CULTIVATION.

[By James Collins, F.B.S., Edin: &c., &c.]

(Concluded from our last.)

THE collection and preparation of Gutta Percha is capable of great improvement. In the case of India-rubber trees it has now been clearly proved that 'tapping,' *i.e.*, just cutting through the bark, is all that is necessary, and that after certain periods of rest, they may again be re-tapped as is the case with the Manna tree *(Fraxinus Ornus)* of Europe. With regard to the collection of Gutta Percha, the *native* evidence is overwhelming against the practicability of "tapping :" the tree *must* be cut down. Still, this statement *may* arise from indolence,—a wish at one operation to obtain the greatest possible quantity, without a thought to future supply, or from the want of sufficient aggregation of the trees within a reasonable space to obtain a sufficient quantity to repay collection by "tapping." Gutta Percha does not flow so readily from the tree as does Caoutchouc, and also more rapidly concretes. The yield in the rainy season is nearly double that of the dry season, due possibly to two reasons,—1st, that the tree has not yet been called upon to use up the Gutta Percha in the elaboration of new tissues, and, 2nd, the greater amount of moisture absorbed causing greater fluidity. The Dutch Government tried to induce the natives to practise 'tapping,' but without effect. "Boring" has also been tried, but without success. However, 'tapping' Gutta Percha trees can only be properly tried in a well regulated plantation, and if successful, will be a great saving, as the quantity obtained by successive tapping would far exceed, in the aggregate, that of a single operation. If it be proved that nothing short of the death of the plant will suffice in order to extract the gutta, then a third more gutta could be obtained by providing wedges, rollers, or other simple mechanical contrivances, in order to allow of the extraction of the gutta on the side of the felled tree next the ground. The implements at present in use seem well adapted for their purpose, and being simple and cheap, need not be superseded.

As to the preparation of Gutta Percha, there is much to be said and also thought out by the aid of direct experiment. The utilizable products as they exist in plants is a most important question in phyto-chemistry. As to what their use and characteristics are whilst *in* the plant, we know little. Thus, Indigo does not exist as Indigo in the plant itself, but is the result of fermentation *after* the juice is extracted from the plant. In Sugarcane again, the juice, even in the cut cane, does not change, but as soon as expressed, it speedily ferments and changes, if not checked, into uncrystallizable sugar. With milky juices, the so-called milkiness is only brought about by exposure to atmospheric influences; and as soon as such exposure takes place, a new set of chemical combinations are inaugurated. Gutta Percha as it flows from the tree is a viscid fluid, acquiring milkiness and concreteness on exposure. Gutta Percha, like Caoutchouc, is a hydrocarbon and splits up, or is resolvable into two resins, *viz.*, *albine* and *fluavile*. Thus, according to M. Payen, a *good* sample of Gutta Percha gave the following results on analysis :—

	per cent.
a.—Pure Gutta (milk white and fusible) ...	75 to 82
b.—Resins soluble in boiling alcohol and consisting of two parts :—	
1.—Crystalbine or Albine, a white crystallized resin	16 to 11
2.—Fluavile, a yellow amorphous resin	6 to 14

It is thus apparent that the change of pure gutta into a resinous-like mass takes place naturally, if means be not taken to stop it. If two bottles of equally pure and identical gutta milk from the same tree be taken, the one bottle hermetically sealed and the other left exposed, the contents of the first will retain its goodness, and that of the other will become resinified and as brittle as shellac. There is also another fact to bear in mind with regard to this proneness to chemical activity in Gutta Percha. In cutting through the bark, many other vessels and cells are ruptured, containing tannic, gallic, and other proximate principles; and the presence of these no doubt accelerates oxidation. These changes I am sure can be retarded and lessened, if not altogether obviated, if the Gutta be *thoroughly well boiled*, immediately after collection; through this *not* being done many an otherwise good parcel has become deteriorated in quality or utterly useless To my mind, indeed, I think that one of the most important considerations with regard to Gutta Percha is this rapid oxidation and consequent resinification it undergoes after it leaves the tree unless by immediate preparation such change is arrested by fixation. The method of preparation has a most important effect on the quality of the product, rendering an indifferent variety, carefully prepared, of more value than a better variety not so prepared. This question is intimately connected with the possibility as to whether any of the substances which have been recommended as substitutes for, or supplementary to, Gutta Percha,—such as the Mudar, Cattimandoo, &c., of India,—can be utilized.

In the 'reboiling' of which I have spoken, the different varieties are almost invariably mixed together, and great harm is done thereby. This mixing is practised chiefly for the purpose of imparting "a tone" to parcels of particularly low quality, by mixing in a certain quantity of good gutta; and frequently the 'tone' consists only of a skin of good gutta over a core of bad. Some of these so-called varieties have no right to be called "Gutta Perchas" unless indeed we extend the significance of the term and admit Kowrie Gum, Gambier, Cutch, and other like substances. This mixing to a manufacturer is a serious matter, and it has yet to be disproved that where a "fault" has been found in a cable it has frequently been caused by the fraudulent admixture of some such resinous substance and its subsequent crystallizing out. When it is borne in mind that a small percentage of such an admixture may render a cable utterly useless at a most critical moment, I am sure that I shall not be charged with hypercriticism or of speaking too strongly on the subject. All the varieties are useful, and by all means let it be seen that they are well boiled; but as to the 'mixing,' the manufacturer at home is best able to judge as to what varieties he can best mix to meet the requirements he has in view.

The very best form in which to prepare gutta for the market is in thin, well-pressed, and well dried slabs, certainly not more than three inches thick. These thin slabs would reduce gross adulteration to a minimum; but where great irregular blocks are sent, the manufacturer has to allow a margin for stones as large as one's head, billets of wood, clay, &c., beside another margin for unnecessary wear-and-tear of machinery. Where slabs are not well pressed, a loss of 25 per cent frequently occurs during the voyage, thus paying freight for so much water; and when not well-dried, parcels frequently arrive half rotten, from fermentation having set in.

The many and various purposes to which Gutta Percha is now applied are legion, rendering an enormous and regular supply absolutely necessary. There are many reasons,—so well known indeed that they need not be recapitulated here,—that for our commercial supplies of any staple article, we cannot long depend on the spontaneous products of the forest; a statement indeed that has the force of an axiom, and is beyond all controversy. Special trees are for the most part scattered over a greater or less extent of forest, thus necessitating long and often perilous journeys before any quantity can be collected. Natives, too, on every possible occasion often maliciously destroy or so maim and injure the trees that they soon wither and die. Recourse therefore must be had sooner or later to conservation, cultivation, and acclimation, in order to keep up necessary supplies. Moreover, when the cultivation of economic plants and their acclimation is undertaken, the various conditions, which are so many elements of success, are the more controllable than when in their wild state. With special regard to Gutta Percha yielding trees, the number destroyed is almost incredible. Thus Dr. Oxley calculated that to supply the 6,918 piculs (1 picul = 133⅓lbs.) exported from Singapore from the 1st January 1845 to 1847, the enormous number of 69,180 trees had to be destroyed; and this statement is by no means overdrawn. From the *Sarawak Gazette*, too, we learn that to supply the 90,000 piculs exported from that district alone from 1854 to 1875, over 3,000,000 trees had to be destroyed. And these are only two instances,—the first shewing the trade in its infancy, and the second that of a limited and comparatively small producing locality. In fact the Gutta Percha trees have only been saved from *utter annihilation* because *young* trees do not yield a sufficiency of gutta to repay the trouble and cost of extraction. At the present time there is a great difficulty in obtaining supplies of the best varieties, and manufacturers require them in much larger quantities than are now obtainable; especially is this

the fact with regard to the maintenance of old and the construction of new lines for telegraphic purposes. It must therefore be granted that the necessary supply to meet this constant and increasing demand will not be forthcoming if speedy means be not taken to ensure it; and this can only be done by the conservation, acclimation, and cultivation of the best varieties. In the Straits Settlements, a splendid opportunity now presents itself to take this matter in hand. We are now in the possession of more power and influence in the Malayan States of the Peninsula than ever we had before, and by means of H. M.'s Residents much can be done in taking charge of the forests. This would be far better than leaving such valuable State property to the tender mercies of Rajahs and other native rulers, who for the most part,—for there are one or two honorable exceptions,—look only to immediate returns and lose sight altogether of future benefit to their States. By letting or "farming" out these forests, for the collection of gutta and other forest products, the working expenses of conservancy would be secured and would result in our obtaining higher qualities and larger quantities at as cheap a rate as is now paid for inferior kinds. In such 'farming' contracts a very stringent clause should find a place—that for every tree cut down, 4 to 6 should be planted. Singapore itself, in the face of so many 'direct' shipments, will not, I believe, long retain her position as the great Eastern entrepôt, unless new fields be opened up for commercial enterprise; and this can only be done by utilizing the undeveloped resources of the Malayan Peninsula. Ceylon, some parts of Assam, and possibly the Nicobars, are likely to prove very suitable for the first experiments in cultivation; and as the subject becomes better understood, and the requirements of the plants ascertained, many other localities in India would alike prove suitable.

On the whole question of Gutta Percha there is still much to be learned, not the least of the desiderata being to identify beyond all doubt the various varieties with the plants producing them. But these queries cannot be satisfactorily cleared up save and except by the personal visit of a well-qualified person to the particular localities where these varieties are actually produced.

TOWN SEWAGE.

ABOUT 1835 a Liverpool merchant imported the first ship load of guano into England, and sometime during the same year, one Mr. Smith of Deanstone, Perthshire, N.B., then an official of the Board of Health at Edinburgh, conceived and laid before the public his ideas of utilizing town sewage as a general fertilizer, and one which would supersede every kind of manure then used. Mr. Smith's name had already acquired honorable notoriety in connection with the subject of land drainage; he was an enthusiast in all matters touching on agriculture—nay, he was even regarded a high authority thereon—but in the question, of town sewage his enthusiasm outran the bounds of sound judgment. At Edinburgh he had seen very favorable results ensue from the use of this fertilizer. He had seen a truly "Foul Burn,"—which for nearly two hundred years had conveyed all the liquid sewage and filth of the town to certain fields on the sea shore, converting a large area of sea sand into meadows yielding magnificent crops of natural and artificial grasses—let out at an annual rental of £30 per acre. He at once jumped to the conclusion that *these results could be reproduced everywhere*, and that from the utilization of town sewage "there could be an unfailing source of revenue. The whole cost of sewers, conservancy, water-supply, parks, fountains, and public embellishments were to be defrayed therefrom;" in fact a long desired and much needed agricultural reform would be brought about. Mr. Smith was *not* a chemist, and in his estimate of the value of town sewage he made some serious mistakes.

I.—He assumed that, in *manurial value*, town sewage contained *half* the fertilizing elements and ingredients of *guano*.

II.—He forgot that the damp and rainy climate of England was unfavorable to the *universal* application of sewage.

III.—He assumed that the water-supply of a town would not exceed 12 gallons per head per diem

These were the *cardinal errors* of his "theory:" his disciples were legion, and official aid was not wanting to back and assist him in the dissemination of his views. Numerous companies were started, and as many model farms, on the town sewage system. But it was not long before the enthusiasts and rash speculators discovered the errors of their ways: the companies and farms collapsed, financial ruin overtaking almost all of them.

If in large towns the water-supply could be kept down to about 10 or 12 gallons per head, town sewage would be a valuable fertilizer, even in England, on almost every description of soil; but where 30 to 40 gallons of water are supplied per head of population, it must be admitted that the sewage is very dilute, and the fertilizing constituents form a very small percentage of the bulk of the sewage—scarcely calculated to supply the wants of lands on which large and exhausting crops of cereals and leguminous plants are grown. In England the practice of applying sewage to stiff soils and soils badly drained, has almost invariably resulted in failure: it has only been in *porous* and *well-drained* soils where success has been complete, and there only for certain descriptions of crops. In his evidence before a Parliamentary Committee, Mr. Christie Miller, the proprietor of the Craigentemy Meadows, near Edinburgh, said "that while the application of sewage to grass in the hot season gave marvellous results, producing a visible growth in forty-eight hours, he was not satisfied with its application to wheat or turnips under ordinary circumstances, and when forced by jet or machinery, the water washed out and laid bare the roots both of turnips and wheat." Sir Joseph Paxton said, "I consider sewage a rough kind of business; you cannot put it in nice forms and ways; I should like very much to apply small dressings to land by hose and jet, so as to wet the roots of plants, if you can show me how to do it; but I have not the slightest notion that you will get the system ever applied to the extent sufficient to remove the sewage of all London . . . . . According to my calculations, the excreta of two hundred and fifty persons can be applied to an acre of land, so it would take about 30,000 acres of land to extract all the absolute growth out of the sewage of 3,000,000 of people (the population of the metropolis). According to a rough guess, you have something like forty gallons of water per head per diem. Now forty gallons would not be very strongly impregnated with matter which would largely develope plants. . . . . Sandy soil, a soil that will allow a very large quantity to pass through it without artificial drainage, is the best. On sand in hot weather you can hardly apply too much sewage to vegetation; in clay lands it is otherwise, *because it cannot pass off*."

In India the conditions of climate are different to those existing in England and Northern Europe. In England, the cultivator has at times too much water in his soil, and his first thought is—"how can I get rid of it?" In India, the ryot's first thought is water! and—"how can I most easily procure it?" What in England might prove under certain circumstances a positive evil and nuisance, would be looked upon in India as a real blessing. For a complete system of sewage, a *complete* water-supply is essential: one is a *sine quâ non* of the other. Small glazed earthenware pipes are laid underground to each house: these pipes get all the *ordure* filth and refuse water from each house and convey these substances into pipes of larger diameter, laid under the adjacent streets; these again are led into the mains, which in their turn terminate in the sewers or closed egg-shaped masonry channels, which in due time lead into the main sewer eventually terminating in the out-fall. In order to facilitate discharge and ultimate distribution, it is often found requisite to pump up the sewage to a high level, this being effected by means of steam machinery working a large centrifugal pump. The sewage being caught in a huge masonry pit or well in which the pump works—arrangements being made whereby the foul air generated by the sewage is consumed in the engine furnaces, and to prevent the deposition of solid matter, silt, and detritus which from time to time is unavoidably washed into the drains—a pipe conveying compressed air into the bottom of the pump well is generally constructed and attached to the engine or engines. The use of this is to agitate the mass and mix it well up with the liquid fluid.

It must be borne in mind, however, that the removal of storm water is not included in a scheme for the removal of sewage, because it would enhance the cost of a drainage scheme to a fabulous extent, inasmuch as the Engineer would have to provide for a discharge due to a *maximum* rainfall over the area to be drained, which in India has often been known to exceed 18 inches of rain in 24 hours. In order to arrive at some idea as to the average which might be irrigated from town sewage in India, the following is an approximate calculation:—

Assuming the population at 30,000, and daily water-supply at 30 gallons per head, we have daily discharge $= 900,000$, $\frac{900,000}{6\cdot25} = 144,000$, and $144,000 \times 365 = 52,560,000$ c. ft. $\frac{52,560,000}{65,000} = 800$ nearly; but 65,000 cubic feet of water is only enough to completely irrigate a *rabi* crop. But meadow and pasture lands would in the hot weather months consume and require double this, and in addition to this, during certain parts of the year, the excessive rainfall would render prohibitory the application of sewage, so that we could not reckon on effective irrigation to more than 300 acres of land. Town sewage is a most excellent and valuable addition to solid manure, but in its dilute form of about 30 gallons per head of population it can never supersede solid manure, poudrette, compost, or cattle dung. It undoubtedly contains a considerable quantity of nitrogen, carbonic dioxide, ammonia, sulphuretted hydrogen, and other organic matters which act as solvents of the earthy phosphates, &c., but a husbandman who trusted *solely* to town sewage in its dilute form, as his only manure, would speedily exhaust the soil. Baron Justus von Liebig, in a letter to the Chairman of a Select Committee of the House of Commons, said:—"The natural laws which govern the permanent fertility of soils and the increase of their produce, are, from circumstances which I cannot detail here, very little understood by the British farmer; and hence arises a fear that the use of sewage, which ought to be a lasting benefit to agriculture, may be regarded after a few years as a veritable detriment by the same farmer who in the first year of its application would assuredly give it his full approbation. In what may be termed its natural state, *sewage is not a universal manure*—like stable-dung, which is efficacious at all times and in all localities—but a special manure, the continued and *exclusive* application of which tends to impoverish the land. Stable dung contains all, a special manure only *some*, of the elements which should be returned to the soil in order to render it permanently fertile. Peruvian guano for instance, belongs to this class of special manures, and experience has shown that in certain parts of Germany and Scotland the application of guano on meadow land which produced in the first years enormous crops of hay or grass, had no later effect at all, and that the same man who at first over-rated the value of guano, eventually cursed its application. Sewage contains ammonia, potash, phosphoric acid; like guano, but phosphoric acid in a smaller proportion. On a soil rich in its natural state in phosphoric acid, sewage will have an excellent effect. It will produce for instance large crops of grass, turnips, and corn, if the soil supplies the quantity of phosphoric acid wanting in sewage; but as in each successive crop a certain quantity of phosphoric acid is abstracted, the total quantity in the soil is, by continual application of sewage, gradually diminishing every year, and a time must come when the phosphoric

acid is insufficient for further crops, and when sewage ceases to have its former effects. By having the turnips eaten on the fields, the soil (by the liquid and solid excrements) is exactly manured as if irrigated with a number of tons of sewage containing the elements of the voidings of the sheep; and the farmer knows that at the beginning of a new rotation he must manure his field with phosphates in order to get the former crops of turnips, corn, &c., in succession. The same field could not be rendered equally fit to furnish the same quality or quantity of produce in a new rotation if it was manured year after year by the voidings, or its equivalent sewage, which would be the same thing. By the increase of his crops in the first year, by sewage irrigation only, the farmer, ignorant of the natural law, would be led to believe that the *same effect* would *continue*, and that he could dispense with other manures altogether, except perhaps, the stable dung which his farm produces. But he would be mistaken, and on finding his error, as he soon would do, the revulsion of feeling caused by it would be baneful. The agriculturist must be taught and made aware that by the *introduction of sewage, his whole system of farming undergoes a change, and that he has an apprenticeship to learn to apply it rightly and economically*, and in order to *benefit* and not *injure* his fields. If clearly understood, and properly managed, the employment of sewage will prove a blessing to agriculture; and those who by unwearied perseverance, have at last seen the consummation of their labours, may justly be looked upon as the benefactors of their fellow-men But loud would be the outcry should the agriculturist, either by his own ignorance or the want of foresight in others, find himself misled. Our name would then become a byword, and instead of gratitude, be recollected with a curse. There are two things which must be done; first, it must be made intelligible to all, that sewage in its natural state does not replace stable-dung in its entire efficacy, and that if used exclusively, it will produce abundant crops only for a time; secondly, that for each crop the composition of sewage ought to be corrected according to the nature of the soil, by adding those ingredients which are wanting in sewage and which the plants to be grown require in the largest proportion.

II.

Town sewage is composed of two distinct kinds of substances,—solid matter suspended, and matter in solution. Of the two the most valuable, from an agricultural point of view, are those substances contained in a state of solution. The following table exhibits an analysis of the solid matter contained in one gallon of ordinary sewage—from the London sewers:—

Organic matter and salts of ammonia	301·82
Sand and detritus of granite	20·69
Soluble silica	12·51
Phosphoric acid	10·41
Sulphuric acid	11·73
Carbonic dioxide	15·59
Lime	21·53
Magnesia	2·87
Peroxide of iron	6·20
Potash	14·13
Soda	1·51
Chloride of soda (common salt)	33·24
Total ...	458·26

The chief sources to which town sewage owes its value are the solid and liquid excreta of the inhabitants; and, bearing in mind their constituent matters, it would be as well to inquire what is the money value of town sewage, and whether the fertilizing ingredients it contains are always available and possess the high value, in an agricultural point, ascribed to them by the enthusiasts who insist on the universal application of town sewage.

One authority, in calculating the value of all the available sewage of London, assumed it to be equivalent to the enormous sum of £1,386,510 per annum. It is needless to remark that the factors which gave such fallacious results were in themselves wrong, because to the potash, ammonia, phosphoric acid, magnesia, lime, &c.—present in sewage—the actual commercial value of these substances was assigned. This was a palpable error. Closer reasoning and a more scrupulous adherence to facts showed that the maximum theoretical value of 100 tons of sewage did not exceed £0-14*s.*-5·92*d.*, "the value being based upon the supposition that the ammonia, phosphoric acid, &c., are as useful as if they were in the form of guano. So they would be, if the sewage in limited quantity and at the proper time were applied to the soil; but town sewage is in most instances collected in a very expensive manner, is distributed over the land during the whole year, and is usually applied in quantities far greater than is necessary for the wants of at least most crops." There are existing in sewage valuable fertilizing materials; but owing to the bulky nature of sewage, or in other words its exceedingly dilute form, it has been found impossible to extract the full value of these fertilizers and to avail ourselves of them in a perfectly convenient form for agricultural purposes. As Dr. Voelcker remarks:—"The value of a manure depends upon other circumstances than its value as shown by analysis. The more bulky a manure is, the less manageable it is, and the less is its practical value; and we cannot calculate the value of any fertilizer by the price of the constituents we put *in* the ground We ought to calculate the value by what we can get *out*, through the instrumentality of certain manures, and following this plan it will be found that the real fertilizing value of the sewage of towns will not on the average be more than a halfpenny a ton." Numerous experiments have from time to time been carried out with a view to eliminate the fertilizing matters from sewage, but the results obtained scarcely warranted the outlay; and even with the *expensive* precipitants used, the average price realized from the manure therefrom, did not exceed £2 per ton. "Under circumstances where it was found impossible to apply sewage *profitably* to land, experiments were conducted in order to determine the best means whereby sewage might be deodorized, thereby mitigating the frightful nuisance attending the pollution of rivers and watercourses. The results of three sets of experiments carried on by order of the Metropolitan Board of Works under M. M. Hoffman and Frankland, showed "that 1,000,000 gallons of sewage required respectively—

	£	s.	d.
66 gallons of perchloride of iron, costing ...	1	13	3
400 lbs. of chloride of lime	2	2	10½
132½ bushels of lime	8	6	6

Three equal quantities of sewage were collected and perfectly deodorized, respectively, by perchloride of iron, chloride of lime, and lime. They were allowed to stand. After two days the sewage disinfected by lime was slightly tainted, whilst that disinfected by chloride of lime and perchloride of iron, remained perfectly inodorous. At the end of three days the lime sewage had become decidedly offensive, whilst the other two specimens still remained free from smell. After four days the odour of the lime sewage had become worse, but that treated with chloride of lime likewise began to exhibit an offensive character, whilst the sewage to which perchloride of iron had been added remained perfectly inodorous. Even after the lapse of nine days the condition of the latter had not changed and in other experiments the same relative permanency of effect had been observed."

The difficulties attending the disposition of sewage in England have not been slow in reproducing themselves in India. Sewage is a necessary evil, and it behoves our municipal and cantonment committees to determine how it can be disposed of in the most complete and efficient manner, and in a way which may prove remunerative to the interests they represent and advantageous to the suburban cultivators. There is no dependency of the British Crown in which agricultural reform is more needed than in India; and by the effective disposition of the sewage of our large towns and cantonments we shall confer one great practical benefit on, and shall have advanced one great step in the *practical education* of, the people. We shall have removed from our market gardener the burdens of grinding poverty and want which are only too commonly the lot of the mass of the agricultural community in India.

The following are the results of sewage irrigation on wheat land on the estates of the Earl of Essex:—

2 Lands 2 a. 1 r. 4 p. with 60,000 gallons of sewage.
„ 2 a. 1 r. 4 p. without sewage.

Sewaged lands gave 11¼ loads of straw, 124 bushels of wheat.
Unsewaged land 9¾ „ „ „ 103 „ „ „

	£	s.	d.	£	s.	d.
And per acre sewaged.						
Straw—5 loads @ 30*s.*	7	10	0			
Wheat—53 bushels @ 6*s.*	15	18	0			
				23	8	0
Per acre unsewaged						
Straw—4¾ loads @ 30*s.*	7	2	6			
Wheat—44 bushels @ 6*s*	13	4	0			
				20	6	6
In favor of sewage				3	1	6
Deduct cost for sewage for 1 acre, *viz.*, 30,000 gallons=134 tons at 1¼*d.*				0	14	0
Clear gain on sewaged land				2	7	6

There is no reason why similar, if not more favourable, results should not be obtained in India from the use of town sewage: everything—cheap labor, a grateful soil, and cosmic conditions—being in favor of the Indian agriculturist. And in many instances sewage is to be had free, municipalities being only too anxious to get rid of it. With improved implements and methods of tillage, a year's operations should give something close on the following figures:—

I. Wheat—*Rabi* crop.		
Grain—50 bushels or 37·5 mds. @ Re. 1·5 per md.		56·25
Straw—4,600 lbs or 57 mds. „ Re ·25 „		14·25
		70·50
II. Tobacco—		
Yield 800lbs. which after deducting all cost of cultivation would be valued at Rs. 8 per maund		80·00
III. Indian corn—*Kharif* crop,		
Grain 80 bushels or 4,800lbs @ Re. 1 per md.		60·00
Straw—dry fodder, 70 maunds @ Re. ·25 „		17·50
		228·00
Deduct—		
Revenue to Government ... Rs.	10	
Manure poudrette 20 tons @ Re. 1 per ton	20	
Cost of tillage operations, &c., on *rabi* and *kharif* crops, as well as a sum equal to 5 per cent. on the value of cultivators' cattle, tools, well gearing, &c,	60	
		90
		138·00

or a clear profit of Rs. 138 per annum on each acre of land.

The production of green fodder crops during the hot weather in India is a question of the greatest importance, considering that for three months (from the end of March to the end of June) the ground becomes as hard as baked clay and refuses, save in the vicinity of canals or water-courses, to yield green herbage of any description. It is under these conditions that a plentiful supply of green food for his cattle and live stock becomes a great desideratum to the ryot. Land laid down under lucerne *Medicago Sativa*, or Italian Rye Grass (*Lolium Italicum*) and liberally dosed with sewage during the months of March, April, May, and June, would easily give monthly crops of magnificent fodder, each cutting yielding from 8 to 10 tons per acre. "Charri" (or *Sorghum Vulgare*) if sown at the end of March and treated with sewage, would also give two good cuttings of fodder during the dry months of May and June. In Northern India, however, none of the large cities are as yet provided with regular systems of water-supply and sewage; and until Government by legislative enactments compel the several municipalities—of such towns as Allahabad, Lucknow, Agra, Delhi, Amritsur, Lahore,

and Peshawur—to elaborate and carry out *complete* schemes for providing their citizens with pure drinking water, as well as for the disposal, in a *rational* manner, of their sewage, we are not likely to see any valuable results on a large scale arising from the application of town sewage to agriculture.

EDITORIAL NOTES.

FROM the last Crop Report we learn that "Agricultural prospects on the whole remain generally satisfactory." More rain, however, would be beneficial in parts of the Punjab and Bengal. Where the rice harvest has been completed in Bengal, the district reports tell us that the outturn has been above the average, and prices rule low in most markets. Rain is still wanted for the unirrigated crops in the North-Western Provinces and Oudh; but although it would be of great advantage to the spring crops generally, it would perhaps do some harm to the mustard plant which is just now in flower in the western districts of the N.-W. P. There promises to be an unusually large crop of rape-seed this year, and prices should rule very low, a result which may give the oil-seed trade a chance of a healthy revival, in spite of the growing partiality for mineral oils. We regret to see that cattle disease continues in Kumaon, and has appeared in Agra, though it is decreasing in Jhansi.

FROM a communication in our correspondence column, it will be seen that Mr. Thos. Routledge is still continuing his interesting and valuable experiments with regard to paper stock from Indian fibres. The home official world is not slow to perceive the important bearing on commerce generally of these carefully conducted experiments, and it seems to us that we in India owe even a larger debt of gratitude to Mr. Routledge. Should he ultimately succeed in introducing new fibres to the notice of European paper-makers, none will be benefited so largely as the Indian public, commercial and agricultural. The plants operated on are all very common in this country, and as a rule they can be obtained at a nominal expense. At the same time it must not be forgotten that it is only a very small proportion of these plants that affords any prospect of profitable manufacture under existing conditions. Mr. Routledge speaks hopefully of the improvement effected by using the ordinary native *dhenkee*, especially in its reducing the bulk, and thereby saving freight. There is another advantage which he has not noticed. When expensive machinery is introduced, a large amount of opposition is sure to be offered by the natives, who are exceedingly conservative in such matters. The native *dhenkee* is a very useful implement for such work, as it acts on the fibres by direct concussion, and there is none of the scratching and rubbing which sundry other processes lead to. The fibre, therefore, while reduced in bulk, is unimpaired in quality. In introducing any improvement in Indian modes of manufacture or cultivation, it has always been found the most effectual plan to take the ordinary native implement and improve on it. The introduction of entirely new modes, leads to a deal of friction among all classes of the community. A notable instance of this is in connection with the Beheea Sugarcane Mill, which is an improved *kolhu*, and which has had a remarkable success.

The merchants and intelligent natives of India ought to move in this matter, and assist Mr. Routledge with such information as their experience may have placed within their reach. By so doing they will help on the inquiry in which he is so devoted a worker. Paper and pasteboard, in fact all sorts of stationery manufactured from fibres, are imported from Europe to the value of Rs. 38,03,154 annually, and we believe there exist no reasons—other than the apathy and indifference of the people of India—why the larger portion of this should not be made in India.

AN interesting letter containing details of an experiment made by a native gentleman, in extracting sugar from Sorghum, will be found in our correspondence columns. Hitherto in this country the "Chinese Sugar-cane" *(Sorghum Saccharatum)* and "Planter's Friend" *(S. Kaffrarium,* or South African variety*)* have been grown almost solely for fodder, for which they are most valuable, as results have shewn. The latter will yield from 4,000 to 12,000lbs of straw, besides a crop of grain per acre. *S. Saccharatum,* however, gives a heavier yield of grain than "Planter's Friend." But although both varieties are specially recommended as fodder producers, there is every reason to believe that they would prove very valuable additions to the crops of this country for the production of sugar. The straw of *S. Kaffrarium* is known to be very rich in saccharine matter. Occupying the ground only about 100 days, it will in that time, and without irrigation, yield from 8 to 10 tons of green Sorghum fit for crushing. In America *S. Kaffrarium* is considered by many to be a better sugar-producer than the Chinese sugar-cane, while all agree that the sugar therefrom is much more easy to crystallize. But quite enough has been written and said and done in the way of experiment, to shew that both the "Chinese sugarcane" and "Planter's Friend" are well worth extensive adoption in this country as sugar-yielding crops. We congratulate our correspondent on the success that has attended his endeavours in this direction. Doubtless the inadequate means of crushing the cane, and purifying and evaporating the juice have to some extent militated against the extensive cultivation of these canes as sugar-producers. But now that Messrs Thomson and Mylne have come forward with their patent sugar-cane mill, which is an acknowledged success, the chief of these obstacles has been removed, and we see no reason why Sorghum should not become one of our staple crops for the production of sugar.

A CORRESPONDENT, whose letter appeared in our December number, wrote to us inquiring for some information concerning the "Dschugara" or "Schugara," a forage plant for cattle. We replied that so far as we are aware the plant is not known in this country by that name and that unless he could give us the botanical term it would be impossible for us to recognise it. Since then we have succeeded in tracing it, and the following description of the plant is taken from a recent number of the *Journal of the Society of Arts:*—

A new forage plant is announced form Central Asia, under the name of "Deschugara." It is said to be largely cultivated in Turkestan, as well as in Poland, where it has given most satisfactory results. From 100lbs of seeds sown, 2,800lbs of grain have been harvested, and a large quantity of straw, which is consumed with avidity by cattle and sheep. The plant has a tall-growing, stout stem, which forms a green cattle food. A variety of the plant ripens three months after being sown. In the climate of Odessa it is described as arriving at maturity as soon as it does in its own country. The chemical composition of the plant approaches very nearly to that of the oat and barely, so that it is extremely useful as a cattle food. The seeds, however, reduced to powder, are used as ordinary flour. Some mystery attended the botanical identification of this plant, when its properties were first made known in the pages of a continental journal, some few weeks since. Mr. Christy has, however, succeeded in obtaining some seed from Russia which, together with information he has also obtained, prove the plant to be that of *Sorghum Cernuum,* a grass closely allied to the well-known "Dhurra" of India.

AN esteemed correspondent sends us the following from Bangalore:—

Our half-yearly Horticultural Show of Saturday last proved a creditable exhibition for Bangalore. In the "flower" department, the standard roses exhibited by Colonel Arbuthnot, 11th (King's) Hussars, and which took the prize, were the best I have seen in India. A new feature was introduced into the show this year, two prizes being offered for the best kept flower-gardens. The first was won by Surgeon-Major Pearl, and the second by Mr. Gibson, Municipal Engineer of the town. The idea is a capital one, as it encourages care and taste in garden cultivation. The show of fruit and vegetables was excellent, and contrasted favorably with the miserable display made at the market on Christmas Eve. The peas exhibited by Mr. T. T. Leonard, who owns a thriving little farm a few miles distant from Bangalore, were of such fine quality, that an extra prize was awarded for them. The same gentleman also exhibited a splendid sheaf of oats, something never before seen at a horticultural show in Bangalore. It may not be out of place to mention here that Mr. Leonard is the first European who has satisfactorily demonstrated that English farming, adapted to local circumstances, will pay in Mysore.

SCIENCE in Agriculture would certainly seem to be taking rapid strides when we hear of man controlling the elements and producing or withholding the waters of the firmament at will. A Mr. G. H. Bell of New York, we read, proposes to build towers 1,500 feet high, through the interior of which he would pump air saturated with water into the upper atmosphere, and so cause the precipitation of rain. By reversing the direction of the blower, a current of air would, when necessary, be drawn down the tube and so annihilate the clouds and prevent excessive rain. A scarcely less startling and more positive announcement is that of a Mr. D. Ruggles of Fredericksburg, Virginias, who proposes to make rain fall at will by exploding dynamite in the cloud region of the atmosphere. Mr. Ruggles, we are told, has already gone so far as to patent his process. It would certainly seem a simpler method than that proposed by Mr. Bell for producing the desired result, though it probably lacks the advantage claimed for the latter of regulating the rainfall at pleasure. It may be worth while noting, however, that both these suggestions emanate from the Western Continent.

JOHN JOSEPH MECHI, of whose death we have been informed by Reuter, was in many ways a remarkable man. Born 78 years ago, he was at an early age placed in a business house, and through his own untiring industry, in devoting the time allowed for dinner to the sale of small articles of which he had secured the patent, he was enabled to set up, in a very small way, as a cutler. In this trade he speedily amassed a handsome fortune, principally by the sale of "The magic razor strop." He then, in 1840, turned his attention to English farming. He may be called the pioneer of scientific farming, and, like most exponents of new systems, was heartily laughed at by the farmers of those days, for his schemes of deep drainage, steam-ploughing, artificial manures, and other improvements. During the forty years he gave his attention to agriculture, however, he lived to see his plans and methods more or less generally adopted, and he himself became a recognized authority on agricultural matters. His model farm in Essex is well known, by name at least, to farmers the world over. He was fond of showing the place to visitors, to whom he explained his many useful improvements in the method of farming; while his letters to the *Times*, written at frequent intervals, and his various treatises on drainage and agriculture have been of inestimable value.

RECENT experiences having shown the necessity of a separate Agricultural Department, and at the instance of the several Revenue Commissioners, the Government of India, in a recent despatch, are said to have recommended to the Secretary of State the formation of a distinct and separate agricultural establishment in the Home Office, to be placed under the immediate charge of an Under-Secretary or an Assistant Secretary of the Department.

OUR last issue contained a few remarks on agricultural banks, which a contemporary informed us would probably occupy a prominent place in the commercial and industrial questions to which Lord Ripon hopes to devote his Indian career. We now learn that Mr. W. Wedderburn, the Judge of Ahmednuggur, with the assistance of some of the opulent and influential residents of that place, intends to open an Agricultural Bank there. It is said that the proposed Agricultural Bank will purchase and supply the poverty-stricken ryot with cattle, and all the necessary implements of husbandry; the ryot, on the other hand, paying the cost of these articles at his convenience. Mr. Wedderburn's proposal is, we believe, a move in the right direction, and as such, deserves commendation.

A STEAM-PLOUGH was recently purchased by the Government of the North-West Provinces, and last month some experiments were conducted with it, under the superintendence of Mr. List, C.E., on the black-soil plains of the Banda district. The following account of the trial is from the *Pioneer*:—

The experiment, so far, has been eminently successful. The plough loosens the soil to a depth of 18 inches and tears up the *kans* stems in a way that could not be effected by any amount of animal power; for a large number of animals cannot be made to work steadily together. The effect of the deep ploughing, however, can only be estimated when next year's *rabi* crop has been reaped, that is, after about fifteen months. We shall then know the increase of produce due to the bringing of the sub-soil to the surface, and Government will be able to decide on the financial success of the experiment. It is estimated that 1,500 acres can be ploughed in the year, but further experience is necessary to frame a trustworthy estimate of the cost of working. Land similar to that in which the plough is now working, when worked up with the ordinary country plough, lets at Rs 7 an acre. If deep ploughing doubles the produce, there is no reason why the letting value should not also be doubled.

SURGEON-GENERAL E. BALFOUR has published a memorandum on the subject of Manilla hemp. Mr. Liotard, of the Agricultural Department of the Government of India, has reported on the materials in India suitable for the manufacture of paper. Several of the fibre-yielding plants are mentioned by him and, amongst others, various species of the genus *Musa*, of the plantain or banana tribe, many of which have been grown in the East Indies from the most remote times. He describes the introduction, in February 1858, of the Manilla hemp plant, direct from the Philippines, into the Madras districts, by Colonel (now Sir George) Balfour. Nevertheless, the Import Trade Returns of the United Kingdom show a large and continually increasing delivery of hemp from the Philippine Islands, now averaging yearly about 20,000 tons, valued about half a million sterling. Dr. Balfour says:—

"I have ascertained from the London Produce Brokers, through Dr. Birdwood of the India Office, that this imported article is the true Manilla hemp from the *Musa textilis*, that the bulk of it is delivered in London where it is made up into cordage and ropes for ships, especially for yachts' running rigging, being very light, strong, and clean, and also for clothes' line But there is no doubt that the Manilla hemp plant, *musa textilis*, grows as well in British India as other species of the plantain or banana genus, and that British India could in a couple of years, supply the London market with all that it could take of Manilla hemp fibre. The prospect of benefiting British India by creating an export trade from it of the extent and value above indicated might well incite to considerable efforts to attain success. In 1861 to 1868 the Madras Revenue Board made continuous efforts to secure the naturalisation of the plants which Colonel Balfour had introduced; but their efforts seem to have been effectual only in the Wynaad from which, by 1877, the Conservator of Forests replied that the Philippine variety had been introduced on several of the coffee estates, where it grows remarkably well, and no doubt is felt there as to the value of its fibre. The attention of the Boards and Commissioners of Revenue, and of the Agri-Horticultural Societies might be re-directed to this plant."

VANILLA has often been recommended as a suitable production for cultivation in Southern India. But the plant is delicate, is somewhat whimsical in its likes and dislikes of situation, and is exposed to obnoxious attacks of various pitiless enemies. A citizen of Bombay has, the *Bombay Review* tells us, during the last two or three years, been trying to cultivate it in the Goa territory—we presume on some of the uplands—and is now able to announce that his experiment is successful. It appears that one essential part of the process is the due fertilisation of the flowers. This has been effected. Not only so, but there are already many fine large pods from which, or from the seeds, the precious extract is taken. These pods bid fair to ripen in due course; and this will complete the success of the somewhat delicate experiment. The gentleman in question has already resolved to extend his nurseries of Vanilla. He thinks that croton oil plant also will succeed in some parts of the Goa territory.

THE following remarks on the "Mahwah" tree (*Bassia Latifolia*), grown in India for food purposes, and highly esteemed, are from the *Chilian Times*:—

The fruit is really a staple crop. It is eaten greedily by all kinds of birds, and by animals, from the goat to the tiger. All the information procurable about this tree confirms the belief that it would prove an acquisition to Chili, and it is to be hoped that some of our farmers will test it here. Its fruit is large, contains 50 per cent of sugar, is eminently fattening in its qualities, and is said to improve the flavour of the flesh of animals to which it has been fed. Another interesting fact is that the flowers, of which a single tree will often produce 400 pounds, are also a favourite article of diet, and are distilled into a spirituous liquor Sugar is also made from these flowers. Besides the *Bassia latifolia*, there are other allied species of value. *B. Buttyracea*, a native of Nepaul, has an oily fruit, of which a sort of butter is made; *B Longifolia* gives oil for lamps; and another species, found in Abyssinia, produces the shea, or Galum butter The height of most of the *Bassia* average forty feet. The trees are highly ornamental, and if introduced here might in time be of great commercial importance.

MESSRS. THOMAS & Co., of Calcutta in a recent report say:—"With reference to a telegram from Munich through Reuter's Agency, lately published in the newspapers, that an artificial indigo, equal to Indian, has been discovered there by a scientific man, we may remark that as far we can ascertain, this intelligence points to no new discovery. It is a fact that artificial indigo can be, and is made, and this has been known for some time past. It cannot, however, at present be made at a price to compete with Indian indigo, and, having carefully inquired into the matter, we believe we are correct in stating that thus far the price of the artificial indigo is nearly three times that of the real article, while it can only be employed by the manufacturers of printed goods."

FROM the Administration Report of the Bombay Presidency for the year 1879-80, we learn as regards the production of cotton throughout the presidency, including the tributary States, that the area of land under cotton was increased by no less than 777,323 acres, the total acreage under cultivation in 1879-80 being 3,758,195, and in 1878-79, 2,980,872. This, be it observed, is an increase in the areas under cotton of only twenty-six per cent; but the outturn of cleaned cotton obtained from the areas sown during that season has increased by one hundred and seven per cent over the preceding year! This is a most encouraging fact, and shows that there are other ways than extending the area under cultivation by which the cotton yield, as well as the yield of other produce, can be increased; for in this instance the result of the year's cultivation on cotton lands shows a better yield on an equal area by eighty-one per cent. The comparative outturn has been better everywhere, varying from 155 per cent in the northern division, to 11 per cent in the Native States situate in the southern

division of the presidency. As regards crops generally, the whole of the season of 1879-80 was unusually favourable, although not equally so in every part of the presidency, the rainfall showing a general average, but not falling timely in many parts.

The Lucknow paper writing of the imports of Indian wheat into England says :—

This is a branch of Indian commerce which is likely to be largely developed, but we are afraid that unless great care is exercised by shippers to see that the wheat is clean and as free from admixture as possible, there will be considerable disappointment in store for those on this side who engage in the trade. Especial care is necessary with such a large competitor as America in the field. In the States, every appliance is available for the shipment of wheat in the best possible condition, and unless shippers in Indian ports are very vigilant they will assuredly consign their grain to a bad market when sending parcels of wheat to London and Liverpool. Some years ago,—in the infancy of the Department of Agriculture and Commerce,—some very useful hints to wheat cultivators were promulgated; we are afraid, though, that very few of the circulars reached actual wheat-growers. It would be a step in the right direction to have these republished in the various vernaculars, and widely circulated in the wheat-producing districts.

From the last Administration Report of British Burmah, it appears that little more than 5 per cent of the total area of the province is under cultivation. There is vast room, therefore, for the development of this, the most prosperous of the provinces under the Government of India. The cultivation consists almost wholly of rice, over 88 per cent of the cultivated land being under that crop. The rice cultivation increased, in the year dealt with in the report, by 160,574 acres, which, it is reckoned, means an increased yield of 120,000 tons of rice. Indeed, the only limit to the extension of rice cultivation in Burmah appears to consist in scarcity of labour obtainable for that purpose. The total land under rice is given for the year at 2,868,329 acres, out of a total cultivated area of 3,257,903 for the whole province.

According to recent reports, the present paddy crop all over British Burmah will probably show a deficiency of from 10 to 15 per cent all round, which may make prices somewhat dearer in Rangoon for exportation, but will hardly affect food prices in the districts, for the mass of the people. Work at the rice mills seems yearly increasing. Some ten years ago the milling and shipping used generally to be completed by the middle of April. Gradually steamers were loaded at the commencement of the rains, and the Bengal famine showed that even in a Burmah monsoon it was possible for cargoes of rice to be sent from Rangoon safely, all through the rains. Since then the shipping season has been gradually extending, and with a constant fleet of steamers trading between Rangoon and Penang and Sigapore, the rice mills are working now about 9 or 10 months out of the 12. As in the fine weather or busy season many of them work night and day, during which time 1,000 bags of cleaned white rice can be milled, the amount of work got through in the course of a year at a Rangoon rice mill is very considerable.

A correspondent writes to us from Rangoon with reference to Government leases of land in Burmah :—

It is to be hoped the visit of the Chief Commissioner to the Tonghoo hill tracts, in which he purports staying a week, will make Mr Bernard propose to the Government of India some more liberal system of giving grants of land than at present exist here. It has been conclusively proved that tea and coffee flourish on those high lands. Potatoes and cinchona have also been grown there, and the climate is said to be cooler in the hot weather than at any of the towns in Burmah. If land were made easy of acquisition, no doubt the Tonghoo hill tracts might in a very few years become a most valuable part of the province, and even be settled by European and Eurasian colonists. The tea, which for the first time has been sold in Rangoon, is equal to all but the best kinds of Assam and doubtless after a little more experience the enterprising pioneer of this cultivation will be able to produce a still better flavoured article. But how can people be expected to go in for plantations, importing expensive machinery and foreign labour, if, under the Burmah Land Revenue Act, they are liable to be turned out of their holding by Deputy Commissioners whom they offend? Leases at the good will and pleasure of revenue officials are not sufficiently attractive to draw to Burmah the capital the expenditure of which our waste lands so much require, and I trust Mr. Bernard's tour to Tonghoo will have the effect of opening his eyes to the mischief likely to be worked in this province unless we get an improved land law, enabling the Chief Commissioner, in such cases as he thinks fit, to grant the freehold of the land which is now lying waste, and which only some such liberal law can bring under cultivation. People will not cultivate or expend money largely on leases, and the enormous power given to Government officials in the districts makes Englishmen view them with suspicion, and everyone is chary of expending much money outside of the chief towns.

The enterprising gentlemen who are so successfully working the Arakan earth-oil wells have, we are told, recently purchased a piece of ground near Kemindine, Rangoon, where they intend erecting machinery to refine the oil. If successful in producing an article to compete with Devoe's American oil, which is now selling there at Rs. 2-8 per five-gallon tin, Burmah should soon become independent of importation from New York, and possibly be able to supply India to a certain extent.

We hear with pleasure that the local Government has caused our article on "Rice Mills in Burmah," published in the *Indian Agriculturist* for December, to be printed in the *Official Gazette*, for general information. This will probably give the article a wider local circulation than if it only appeared in the agricultural organ, and speaks well for the administration in trying to draw public attention to this important trade of Burmah.

That Japan can afford to compete with any rice-growing country in the world, all other conditions being equal, would seem to be evidenced by the statement of cost of rice production furnished by the Tokio Chamber of Commerce. A recent issue of the *Japan Gazette* tells us :—

The average cost appears to be yen 2·45 per koku, and the average selling price, yen 4·45, so that the producers' first profit is considerable. We of course, deal with these prices as silver, not paper rates, and proceed upon the assumption that if rice has appreciated in relation to currency, silver has increased in value in the same proportion. Further, that in view of the satisfactory harvest and large surpluses, the value of rice for silver is unchanged. Under these conditions there is no reason why Japan should not be a formidable competitor to Saigon, Rangoon, and the other eastern rice ports; nor why large sums of specie should not annually flow into this country to encourage increased production and activity. Ordinary Japan rice at $5 silver per koku would command a large sale.

The Japanese Government have established an agency in London for the sale of paper of various kinds manufactured at the Tokio mills. The quality of this paper is pronounced to be all that can be desired, but the price is practically prohibitory. If they were to turn their attention to supplying the manufacturers at home with the raw material, there would be more likelihood of finding a profitable market.

We see that the Rajah of Sarawak has issued a proclamation inviting Chinese to settle with their families on the Rajung river in that province, and offers them very tempting terms. The island of Borneo offers a vast field for enterprise, being almost wholly undeveloped, but it is so rich in natural resources, possesses so fertile a soil, and enjoys so excellent a climate for the tropics, that it cannot fail ultimately to attract the attention of capitalists and planters. At no very distant date, doubtless we shall see Labuan and the Borneo Settlements in direct and regular steam communication with Hong-Kong. Mr. Lees, the Governor of Labuan has been instructed to assist in opening trade with Borneo, and to adopt such measures as are, in his opinion, best calculated to develope commercial relations with that country. This is an acknowledgment, at all events, of the importance of cultivating a promising field for the extension of trade, and may perhaps be regarded as a sort of preliminary step to recognising the cession recently made to the Dent Overbeck Company.

Trustworthy information, the Press Commissioner tells us, has been received regarding the attempts to introduce the cultivation of the opium poppy in the Portuguese territories of Mozambique, which shows that the results are more unfavourable to the success of the experiment than they were at first supposed to be. The yield of opium is found to be not more than one quarter that in Malwa, the plants give only one-third the number of capsules, and the African drug is considered inferior in quality. Out of forty-two Indian cultivators who had been imported to introduce the Indian system of cultivation, seven had died; whilst the Parsee engineer who had been employed to attend to the irrigation works, had left the country.

MISCELLANEOUS ITEMS.

Our acknowledgments are due to Major Nutt, the President, for a copy of the prospectus of the Wadhwan Agricultural Show, to be held on the 10th, 11th, and 12th instant. Prizes we see will be awarded for horses, ponies, cattle, sheep and goats, camels, asses and mules, poultry, fresh fruits, vegetables, grains and seeds, oil-seeds, fibres, cotton, Indian tobacco, dyes, forage plants, manures, and agricultural implements.

THE annual Show of the Agri-Horticultural Society will be held in their garden at Allipore on the 3rd instant. We are given to understand that their Excellencies the Viceroy and Marchioness of Ripon and the Hon'ble Sir Ashley Eden intend honoring the show with their presence.

AN agricultural exhibition of animals and agricultural products, combined with trials of agricultural machinery, ploughing matches, wrestling, and fire works, is to be held on a large scale at Lucknow on the 8th, 9th, and 10th of March next.

A HORTICULTURAL exhibition is to be held at Mahableshwar on or about the 25th April. There are to be three classes : flowers, fruits, and vegetables ; and about one hundred prizes, varying from Rs. 20 to Rs 2.

WE find from a report (a fortnight ago) in the local *Gazette* that the outturn of the crops in Assam is expected to be a bumper one, one-half having been already gathered in. The weather is reported as "seasonable."

IN the Nepal Terai the rice crop is not likely to exceed an eight-anna outturn.

THE French Government in Saigon have increased the export duty on rice, from the 1st January, from 10 cents to 15 cents per picul, but French Colonies and French ships are to be exempt.

THE failure of the crops in the Southern and South-Eastern Provinces of Russia is reported to be so great that when spring arrives, nearly two million people will be without food.

MESSRS. HIGGINBOTHAM & Co, Madras, have brought out a very valuable publication printed in English and Tamil, under the title of "Extracts from manuals of the more deadly forms of cattle diseases in India," by Messrs Thacker and Hallen, Veterinary Surgeons of well-known repute.

HIS Highness the Maharajah of Cashmere has applied for permission to engage the services of three Frenchmen for working the liquor distillery which has just been established at Srinuggur, and for generally supervising the vineyards and other industries in his State.

WE observe that Mr. James Mylne of Beheea in Shahabad, Bengal, Zemindar and Indigo Planter, has taken out a patent for improved spindles for rollers used in Thomson and Mylne's patent sugar-cane crushing mills

CALCUTTA absorbs 44·04 per cent of the whole trade of India; Bombay, 37·22; Rangoon, 5·76; Madras, 4·55 ; Kurrachee, 1·42. The trade at any one of the other Indian ports does not reach 1 per cent of the total trade of the country.

THE Ivory supply of the world causes the destruction of 100,000 elephants annually.

THE quantity of salt made and imported on which duty is paid in India is about $25\frac{1}{2}$ million maunds, and the duty received £6,528,681 ; the charges to be deducted are about £260,000

THE importance of the hide and skin trade of India is shown by the fact that it stands seventh in the list, and that it has attained to the yearly value of £3,750,000. The total quantity of raw and dressed hides and skins now exported from India annually is but little short of 1,000,000 cwt.

THE Upper Provinces are promised a new and picturesque industry in the shape of an experimental Ostrich Farm, the material for which is to be brought from the Cape. Moreover, the scheme is fathered by a very practical man.

THE paper railway wheels which have been tried in America are said to be a success. One carriage having these wheels has run 100,000 miles with very little wear.

ABOUT 75,000 miles of hoop iron—enough for a threefold girdle round the earth—will be needed to bind the forthcoming American cotton crop, if it reaches the amount of bales predicted by statisticians, or 6,000,000 bales.

THE Grand Opera at Paris has just been lit with cork-gas. The manufacture of cork-gas is likely to extend, as the cork-oak (*Quercus suber*) grows in vast quantities in Southern Europe and Northern Africa In fact, Spain and Portugal supply almost all the cork used in the world. The tree is very thriving, and produces its deep layers of bark for one hundred and fifty years.

THE culture of jute has, as stated in our last issue, been commenced in Egypt. Hitherto Bengal has been the great centre of production, although attempts to grow it have been made in parts of America and Australia. Egypt possesses the requisite soil and climate for its culture. As it yields a crop of about a ton an acre, worth at least £14 to £20, the culture of jute may come to be a rival of cotton in Egypt.

IN 1829 the export of jute from Calcutta was twenty tons only, worth about twenty pounds. Now the quantity exported annually is 350,000 tons—nearly two million bales—valued at about six million pounds sterling. This large quantity does not include the enormous supplies retained in India.

RECENT reports state that Chinese in the interior of China are loudly complaining of the want of rain. In some places around Soochow and Nanking they have had none for five and six weeks, while at Chinkiang it has not rained for nine weeks.

A CHINA paper writes as follows:—" A telegram was received in Yokohama lately, stating that the sugar crop in Formosa is very bad this year, and will be 400,000 bags less than the usual outturn. We cannot guarantee the exact number of bags as above-mentioned, but it is certain that the sugar crop is very poor."

THE opium plantation on the Zambesi river is, we observe, said to have a hundred and seventy acres of land under poppy this season. This is a small beginning, but the venture has been so far successful as to induce its conductors to indent on this country for a second instalment of Malwa cultivators.

OFFICIAL PAPER.

ON THE CULTIVATION OF JALAP.

FROM A. Jamieson, Esq., Superintendent, Government Botanical Gardens, to N. A. Roupell, Esq., Acting Commissioner of Nilgiris, dated Ootacamund, 9th July 1880, No. 115.

With reference to your docket No. 293, of the 2nd instant, and Official Memorandum, Revenue Department, No. 191, dated 1st instant, I have the honor to submit the following report on the cultivation of jalap.

Area under Cultivation.—The propagation of jalap was commenced in the Ootacamund gardens in 1877. Our stock then consisted of 100 plants that had been grown in the gardens for ornament. Although the tubers increase to a large size, and the stems grow luxuriantly and flower profusely, the flowers do not fertilize freely and produce but few seeds in the climate of Ootacamund ; consequently, the increase of the plant has been confined almost entirely to propagation from root and stem cuttings. This work has been carried on steadily until there are now upwards of 25,000 plants and root cuttings permanently planted out. The tubers were at first planted 4 × 4 feet apart, but it was found that they did not exhaust the land, and throve equally well when planted closer. They are therefore now planted in rows three feet apart and the distance between each plant in the row does not exceed two feet, so that 25,000 plants give a total area planted of 5 acres. The cost of cultivation, weeding, &c., is also much reduced by close planting.

Method of Cultivation.—Having no data to guide me regarding the climate and soil which are natural to the jalap plant, I tried it in a variety of situations, and now find that it thrives best in a tolerably rich, dry and friable loamy soil,—in fact, conditions of soil that are indispensable to the production of good potatoes seem equally necessary to the growth of jalap. Good grass land is preferable to open rich forest land ; when planted in the latter, it has a greater tendency to produce a mass of succulent roots than to form tubers. In opening land for the cultivation of jalap, several acres of well-drained grass land sheltered from the south-west winds, and with a stream of water on or near it, should be selected. If the land be very steep, it should be laid out in terraces 10 feet wide. The terracing should be completed by the end of January, and the ground dug over to the depth of two feet and left exposed to the action of the sun until the beginning of April, when it should be drilled, manured, and planted with potatoes (an early ripening variety of kidney would be the best variety to plant). The potatoes should be lifted in June, the land cleared of weeds and forked over in order that the manure (not taken up by the potatoes) may be incorporated with the soil. The ground is now ready to receive the jalap plants, which should be planted when the tubers are about the size of pigeon eggs in rows (across the terraces) on ridges a few inches higher than the general level of the ground, in order that they may be raised sufficiently high to prevent water from lodging immediately around them. If the weather be dry, the plants should be watered occasionally until they have begun to grow ; when once established, ordinary garden culture, as to weeding, &c., is all that is necessary.

Jalap is an herbaceous plant throwing out twining stems, which should be supported by stakes or wire trellaces in the same manner as ordinary garden peas are. The stems die down annually, and the tubers remain dormant for two or three months. In addition to the aërial stems, jalap throws out a mass of under-ground shoots which emit roots and form tubers at intervals of from 6 to 9 inches. It is from these under-ground shoots that the greater proportion of our plants have been raised. When cut about three inches long and planted, they root freely and gradually enlarge into tubers ; by this means the plants can be multiplied to any extent.

In the year 1879-80, 178 lbs. of dry jalap tuber was supplied to the Medical Department which was valued at Rs 2-4-5 per lb. = Rs. 893-12-1. The crop for the current year to be delivered in February or March next is estimated at 400lbs. and that for 1881-82 at 800lbs. and from February 1883, 1,200 or 1,500lbs. or more annually according to the area brought under cultivation. One acre of land planted as I have described should at the end of three years produce 5,000lbs. of green tuber, which will yield when thoroughly dried 1,000lbs. of jalap powder. The cost of cultivation, collection, and drying of the root for the same period will not exceed Rs 350. I therefore estimate that dried jalap tuber can be produced in Ootacamund at a cost of four annas and ten pies per lb.

No regular season has yet been observed for collecting the tubers or method adopted for preparing the drug for use, but I have no doubt it will be found most advantageous to dig them up when the herbaceous stems have died down and the tubers are dormant, which on the Nilgiris will be during the months of January and February.

The propagation and growth of the jalap in the Ootacamund gardens has so far been very successful, so much so that I consider it highly desirable that the area should be extended until there are at least 10 acres put under cultivation. From the Chemist's analysis and valuation published in G. O. No. 1027, dated 1st July 1878, there can be no doubt entertained as regards the commercial value of Ootacamund-grown jalap.

SELECTIONS.

SORGHUM CULTIVATION IN MADRAS.

A CORRESPONDENT writes to the *Madras Mail*, as follows :—

In your issue of 4th December, you publish some remarks on experiments which *Sorghum Saccharatum* conducted in the Coimbatore district.* I am unable to lay my hands upon the exact data I collected regarding *Sorghum*, but may briefly state the following facts to show what has been, and can be, done in Madras :—

I selected a piece of clay land in Kilpauk, irrigated it slightly, so as to allow a country plough to penetrate the surface, and after ploughing, broke up the clods with small crowbars, and removed the bulbs of the coarse grass, its only produce. The ground was so hard that I had great difficulty in digging in with crowbars a dressing of stable manure. I then planted *Sorghum* in drills, about 9 inches apart, and irrigated with Red Hills water, but the crop failed, after coming up a few inches. Having again drilled the ground I planted *Sorghum Saccharatum*, and when the young plants had grown about 4 inches, I gave a top dressing of poudrette, manufactured on a new plan, whereby valuable chemical products, hitherto generally wasted, are saved and utilised; this was then worked below the surface. I continued irrigation twice weekly and commenced cutting the crop as green fodder, whilst the seed was still unripe, a small patch daily, taking care to leave about 6 inches of the stalk, which immediately sprouts afresh. From this plot I gathered three complete cuttings, equal to twenty-five tons per acre, in less than five months. After each cutting the crop became thinner, owing to many roots dying; but some of the plants seemed to gather strength, and produced several stalks apiece. From another plot, of slightly better ground, that I had prepared for other crops, and manured with poudrette, I gathered green fodder equal to 35 tons per acre in the same time. I am aware that I exercised more care and spent more time, manure and water than would ordinarily be practicable; but, on the other hand, the soil was exceedingly poor, and the heavy outturn is mainly attributable to the fertilizing influence of the poudrette which was brought into immediate contact with the surface-feeding roots of the *Sorghum*. This crop is, however, so valuable for fodder that it should pay well for attention. In its green state *Sorghum Saccharatum* contains over 10 per cent of sugar starch and other carbo-hydrates, and I may mention that my horses at all times preferred it to their grain. I was not very successful in securing seed as the parrots and squirrels destroyed the heads before they had matured.

CAROLINA PADDY.

LAST November Mr. C. Benson, the Acting Superintendent, Government Farms, Madras, forwarded to the Board of Revenue samples of the paddy received from the Government of India together with a sample of genuine Carolina paddy, and said :—"The samples do not appear to me to be other than specimens of common paddy, known as *kar* in this neighbourhood. The husk is of a dark dirty colour, and the rice is, throughout, more or less red; whereas Carolina paddy is characterized by the bright golden color of the husk and the fine white rice it yields. I observe that Mr. Dickson acknowledges that the paddy has lost the color of its husk, but I am extremely doubtful whether that ever takes place, for we have never found it to occur; and probably the true Carolina paddy has been lost in Ceylon. We have frequently observed this in the case of samples raised in this presidency. It is probably due to the sprouting of shed seed from former crops of native paddy on land where Carolina paddy has been grown, and as the latter variety does not flourish under the usual native system of management, the former has suppressed it. The chief recommendation of Carolina paddy lies in the whiteness of the rice it produces, and if it should be the case that in Ceylon this character really undergoes a change, its value is lost, for that variety undoubtedly requires greater care in its cultivation than native varieties."

The Board remark that the Ceylon samples forwarded by Mr. Benson are so unlike the genuine Carolina rice, that the Board are inclined to think that it may not be Carolina rice at all. But if it be, it has evidently deteriorated so seriously as to render any further experiment upon its cultivation undesirable, as it has lost the principal characteristics which render it valuable.

THE CRUSHING AND CLEANING OF COTTON SEED.

IT has been said that cotton seed cannot be crushed in this country with a reasonable prospect of realising as much by the oil produced as the cost of the crushing amounts to. This too, it has been said, is owing to the quantity of fluff that adheres to the seed; which means in other words, the bad or imperfect cleaning of the cotton. Now the crushing of cotton seed has become a very important industry both in England and America. Indian cotton, it is perfectly well known, produces, after cleaning, less of the staple and more weight of seed than any produced elsewhere. Here are two shapes in which the Indian cultivator may gather to himself the profits of his labour; first the cotton, and next the seed. From these two sources, it is questionable whether the oil might not yield the *larger* amount of profit. While New Orleans cotton in cleaning, loses one-third or thereabouts, Indian cotton under the same process, loses two-thirds, and the two-thirds loss must of course be mainly in seed. What becomes of this immense amount of seed? Throughout the United States, there are at this moment more than forty cotton-seed-oil mills in full operation. The annual quantity of seed converted into oil amounts, even now to, 410,000 tons. The average yield of American seed is about thirty five gallons of oil to the ton, and even then there remains a "by product" of 750 lbs. of oil-cake, far better fitted for the food of cattle than the seed itself. England, where the enterprise was first carried out—was, up to recently mainly supplied with seed from Egypt. Although the export of seed from Egypt to England in 1860 was only 1,000 cwts, has by this time risen to about 5,000,000 cwts. More than *ten crores of rupees* are annually being paid by England for cotton seed; and is India to have no share in this great harvest? What folly to talk of the cotton that adheres to the seed rendering it useless for the purpose of crushing. Why not, before submitting the seed into the crushing mill, pass it gently through a well constructed furnace, and singe from it the adherent cotton, as our cooks at home singe their geese before cooking them? That is one way; another would be to brush off the fluff by a properly constructed winnowing machine.

* See our last issue p. 12,—ED., *I. A.*

FAMINES AND CANAL IRRIGATION.

IN the event of a total failure of the rain required to prepare the soil for the *rabi* sowings,—and for a large portion of these provinces this calamity has been but just missed this year—it becomes an interesting problem to calculate what would have been the actual value of a canal running through the distressed parts. We may take it for granted that under the circumstances supposed, no crops whatever could be grown without artificial irrigation, either by canal or well, and for the purposes of our problem may work out the actual value of the crops grown, and compare it with the cost of constructing the canal. In 1878-79, a year of famine, it was computed in the Irrigation Revenue Report of that year that the Ganges Canal, with a length of 598 miles of main channel, produced crops worth Rs. 4,11,02,350, or Rs. 66.300 per mile, the capital cost of the canal being Rs. 51,500 per mile. Thus supposing a season in which the *kharif* crop failed entirely, and there were no rains to enable the *rabi* to be sown, it may be said that the canal would more than cover its original cost by the value of the produce, which could not have been bought to maturity without it. Again, if we take out the value of the canal in the same way based on the *rabi* crops only, which we will assume, could not be given at all without its aid, we shall find the value of crops raised to be about 29,500 per mile of canal, or 57 per cent of the cost of its construction. On the supposition, therefore, that a draught occurs once in 10 years only, it would appear that a canal which would hardly pay its expenses in an ordinary season would be worth constructing as a protection against total failure. The above figures deserve consideration in calculating whether it is worth while to construct such a work as the Sardah Canal, which, we believe, is now to be started as a relief work in the distressed districts of Oudh. It seems clear that in a season like the present, when *kharif* has produced no more than a four-anna crop, and when the *rabi* cannot be sown, the canal, had it been in existence, would have saved its own value in crops. Turning again to the canal returns for 1877-78, we learn that an area of 1,037,000 acres was cultivated by a canal 593 miles long, which cost Rs. 51,500 a mile. These figures will enable those who are skilled in the average cost of sinking wells in such a season, and who know the area such wells will protect, to calculate whether the wells or canal would be the cheaper.—*Pioneer.*

SAWDUST FOR BEDDING AND MANURE.

ONE of our most valuable correspondents writes :—We have tried for two years dry sawdust in the cows' stable, and on the whole like it better than any bedding we ever tried. It makes a more comfortable bed, completely absorbs the urine, and the cow is kept clean with less labor than when any other is used. The objection to salt marsh sods, dried, or to headlands, and dry muck, is, that they soil the cow, and make it necessary to wash the bag before milking. Straw of all sorts soon becomes foul, and without more care than the ordinary hired man is likely to bestow, soils the cow's bag also. Dry sawdust is clean, and makes a soft spongy bed, and is an excellent absorbent. The bag is kept clean with the aid of a coarse brush without washing. A change of 15 bushels in a common box stall, or cow stable will last a month, if the manure, dropped upon the surface, is removed daily. The porous nature of the material admits of perfect drainage, and of rapid evaporation of the liquid part of the manure. The sawdust is not so perfect an absorbent of ammonia as muck, but it is a much better one than straw, that needs to be dried daily, in the sun and wind, to keep it in comfortable condition for the animals. In the vicinity of saw and shingle mills, and of ship yards, the sawdust accumulates rapidly, and is a troublesome waste that mill-owners are glad to be rid of. It can be had for the carting. But even where it is sold at one or two cents a bushel, a common price, it makes a very cheap and substantial bedding. The saturated sawdust makes an excellent manure, and is so fine that it can be used to advantage in drills. It is vauable to loosen compact clay soils, and will help to retain moisture on thin sandy and gravelly soils. There is a choice in the varieties of sawdust for manure, but not much for bedding. The hard woods make a much better fertiliser than the resinous timber. To keep a milch cow in clean, comfortable condition, we have not found its equal.—*American Agriculturist.*

ON SOOT AS A GARDEN MANURE.

THE value of soot as a manure appears to be slowly but surely impressing itself on all classes of cultivators. That it is a powerful fertilizer, requires but little in the way of experiment to prove. The rich verdure it imparts to any plant to which it may be applied, either as a soil-dressing or as a liquid manure, is powerfully demonstrative of its manurial qualities. We apply it to everything: to kitchen garden crops, to fruit trees, and to pot plants, both foliage and flowering, with the most satisfactory results. It is applied broadcast to the open quarters of the kitchen garden, and dug in with any other manure that may be used along with it; it is mixed with potting soil, either by itself or along with any other fertiliser that it may be desirable to add to any compost; and it is mixed with our cow urine, or with any artificial manure that we may desire to use as a liquid manure, and in every case with the best results. It is especially valuable as an application to all plants that are liable to attacks of insects or worms at the roots. Carrots, parsley, and parsnips, which are subject to fatal, or at least damaging, attacks of wire-worm, may be so invigorated by constant and regular applications of soot-water, that they will resist the attacks

of these earth posts, and these themselves appear to be destroyed by the qualities of the manure. We make it a rule to save every particle of soot that is deposited in our chimneys and flues, and obtain a good supply in addition, as occasion requires, from the nearest chimney-sweep, and would advise our readers to do the same.—*N. B. Agriculturist*.

THE USES OF STRAW.

IN travelling through the country we see, in every direction, great heaps of straw (and sometimes hay), which are not in a condition to be more profitably utilized. First these materials are most valuable for food for stock. Too frequently, we are satisfied, farmers in the West lose by growing more of some food crops than they keep stock to consume it. The result is loss upon hay, straw, and especially corn-fodder, which becomes comparatively of little value when not utilized for stock food. There are, however, other uses than food for these products. Their next most profitable employment would be in the construction of temporary shelters for stock from the storms and cold of winter, on farms in which permanent buildings have not been erected. By all means, then, let the materials, now apparently going to waste, be appropriately applied in this direction. Their being so utilized may save many a bushel of grain or ton of hay used as actual food, for it is as well ascertained that stock, exposed to storms and cold, require more food to keep life and health in them, as that it requires more fuel to keep a rickety open house warm, than it does to keep comfortable the better constructed. Besides, if this extra food is not given, unsheltered stock comes out of the winter poor (if not diseased) and half the following pasture season is over before the stock has attained the condition of flesh it had the previous fall. Such stock if in condition to be well-fatted at all in one season can only become fat late in the season when prices are usually at their lowest. Hence the necessity for good shelters and good feeding during winter to enable early fatting in the summer. But if more straw corn-fodder &c., are on a farm than is needed for food and shelter, it should be used for bedding stock which adds to the comfort and hence thrift of farm animals. If, however, these materials are not actually needed for food, shelter, nor bedding for stock, there is still another use to which they may be profitably appropriated. For example: Every farmer knows, or ought to know, if he does not, that the winter grains and grasses, fruit trees, shrubbery, &c., need shelter as well as does stock, and for a similar purpose—to protect them from the cold of winter and enable them to make an early, vigorous growth in spring and early summer, the natural growing season of plants carried through the winter in a growing condition. Perhaps as profitable use as can be made of surplus straw, damaged hay, &c., is to spread them evenly over wheat and grass fields. This prevents the winds from blowing the soil away from the roots of wheat plants, and enables them to grow during the winter as does a light covering of snow. This again gives an early start in spring, and hence early maturity and perhaps escape from rust, injury from insects, &c. The same is true in the application of straw as a covering or mulch for grass during the winter. This has been frequently tried with eminently satisfactory results on both sides of the Atlantic. In a valuable work on "Farming with Green Manures" by Dr. Harlan of Wilmington Delaware now before us, we find the result of covering grass land with straw made by the celebrated English agriculturist Gurney. In one instance grass covered with straw gave him in one month 5,870 pounds per acre; the same kind of grass uncovered, 2,207 pounds. No rains fell during this experiment. Another covered plat in one month gave 3,460 pounds per acre, while a similar lot not covered gave but 970 pounds. In another experiment, clover covered grew six inches, while that uncovered grew but one-and-a-half inches. These experiments may, and perhaps do, illustrate unusual advantages derived from top dressing with straw. But there can be no doubt of the general advantage. The effect of top dressing grain or grass with straw is, first; protection from the influences of dry, freezing, driving winds &c., secondly; as a preventive against the evaporation of moisture, often highly injurious to grain and grass in spring or early summer, in our latitude, and thirdly; the actual manurial advantages to crops as decomposition advances. By all means, therefore, our farmers should spread their surplus straw upon their wheat and grass fields, as early as practicable, instead of wastefully allowing it to rot in heaps and pass off into the atmosphere in the form of gases during decomposition, or the more wasteful practice of burning their straw. In spreading straw on grass and grain, care should be taken to have the material spread evenly over the ground, and not in bunches to smother out the growing plants. With the prevalent mode of securing hay with us, straw perhaps may not be spread on meadows with quite so good results, as our horse rakes would be likely to take up that remaining unrotted and mingle it with the hay to its damage, especially to hay shipped to market. But on pastures, there can be no doubt that straw and corn stalks may be beneficially applied at anytime.—*Journal of Agriculture.*

PEPPER IN CEYLON.

THERE is a cultivation now in its infancy in Ceylon which should develope a very considerable trade, and that is pepper. Many years ago when first introduced into India by the old East India Company, it was declared a failure, "although they admitted that the hermaphrodite plant had been withheld from them by the natives, and consequently the plant had been starved into celibacy." Notwithstanding their first failures, pepper ultimately became the most important article of their exports however. To-day the Malabar pepper is the kind most sought after, and the production is annually over 5,000,000 lbs. But to appreciate the enormous trade done in pepper, take the Sumatra export which is over 30,000,000 lbs yearly. Now, as the cultivation takes a good deal out of the soil, and is said not to be worth growing after say, the tenth year, it is evident that there is always room for its extension in Ceylon and elsewhere. Regarding its cultivation, the writer has had some experience with this product, and can affirm that it grows better in the *open* than in *shade*. The native method of growing it is to plant five feet apart, and support it on a fence of sticks; the pepper grows luxuriantly where it has much moisture, and hence valleys are the most favorable situations for its growth. After the first planting the vine requires but little attention, being left to its fate for twelve or eighteen months, when whole, the plant, with all its branches, is buried in such a way "that only a small arch of the stem remains above ground. From this arch new shoots soon sprout out, three or four of which are allowed to climb up the props, and are able to produce flowers and fruit in a year after this operation, by which practice the strength and vigour of the plant—by the multiplication of its organs of nourishment, the roots—are increased, and it cannot fail to produce large crops of flowers, and bring its fruit to its greatest perfection.

CASSAVA ROOT.

RICE has for so many centuries been the staple article of food in large tracts of this country, that if roast beef and plum-pudding were the offered famine diet, they would in all probability be rejected. Cassava root, however, is in every respect superior as an article of food to rice, and may be obtained at infinitely less cost. Throughout Eastern Africa this takes the place of rice, and is largely consumed both by European and natives. India alone, until every recently, has stood apart from the cultivation of this most nutrient vegetable. It is satisfactory, however, to see that the cultivation of this root is now being prosecuted to a considerable extent in Jaffna and also in Ceylon. Irrespective of its value as a cheap and wholesome food, it is of good commercial repute for the manufacture of glucose and sugar, for which purposes it has already been rather extensively shipped to England from the east African coast. Owing to the abundant rain on that coast, three crops of cassava may be obtained in the course of the year. It may be doubted if more than two crops could be obtained on this side of India; but even this, with the small amount of labour required, would unquestionably be found more profitable than the cultivation of rice. The Ceylon planters, always wide awake to every new move, have made a beginning at the growth of cassava, and we shall probably next hear that they are largely exporting it. The *Ceylon Observer* gives the following as the rule for planting, which differs but slightly from that followed in East Africa:—

After preparing the ground in beds, the stalk (cassava) is cut up in pieces of nine inches, in length and planted two inches in the ground, and watered daily for the first two weeks; and subsequently once in three days. After six or seven months, according to the nature of the ground, the root is dug out. The largest root measures three feet in length and six inches in diameter. Immediately it is dug up, the outside bark is carefully peeled off and the root cut up in thin slices and dried up for powdering: the flower thus made is used for baking hoppers, *puttu*, and other native cakes. It is also used for adulterating wheat flower.—*Bombay Review.*

JUTE IN EGYPT.

WE see that two samples of Egyptian jute sent to Dundee for examination and report by practical spinners have been valued, one at £15, the other at £17 per ton of 20 cwt., and these prices are rather higher than the finest qualities of Bengal jute command. Presently an opportunity will be given to compare larger samples, as the administration of the Daira Sanieh are about to make a shipment of a few bales, the produce of experiments on their lands, and another proprietor, an Englishman at Mansoorah, who has taken a warm interest in the matter, is about to send to Dundee a bale. It appears that one obstacle to the success of jute culture as yet, has been the ignorance and prejudices of the fellahs, who thought it no better than a weed; but curiously enough they soon found out the value of the fibre as applicable to rope-making, and it is added that the mysterious disappearance of much of this season's produce may be accounted for by this discovery. Notwithstanding all adverse influences, however, a firm belief in the new culture seems to be growing up, and as private arrangements have been made by the administrations of the Daira and the State. Domain lands to procure a supply of fresh sound seed from India, a material extension of cultivation may be looked for next season under favourable conditions, as the Bengallee coolies lately introduced have been retained to supervise operations. Practical experiment has conclusively demonstrated that on suitable soil and with the same care that is bestowed on the cultivation of cotton, jute can be grown successfully in Egypt, some of the plants on the State Domain lands being superior to anything produced in Bengal. The Egyptian papers publish elaborate calculations as to the profit certain to attend the enterprise, and these seem wholly free from exaggeration. It will of course be a work of time, as was the introduction of the cotton culture, but too many powerful interests are in favour of the jute experiment to let it result in failure from any want of fair play in giving it a trial. European capital is pouring into Egypt still it must be remembered, and so long as that goes on the peasantry will have a powerful stimulus to improve.

JUTE CULTURE IN AMERICA.

LETTER FROM PROF. WATERHOUSE TO THE MERCHANTS' EXCHANGE.

THE Directors of the Merchants' Exchange in their meeting October 23, received a letter from Prof. S. Waterhouse in relation to the proposed culture of jute in the Southern States, as follows:—

WASHINGTON UNIVERSITY,
ST. LOUIS, OCT. 23, 1880.

ALEX. H. SMITH, President Merchants' Exchange.

DEAR SIR,—That the specimen of jute which was sent you, attracted so much attention on 'Change is a very gratifying fact. Ever since my visit

to India in 1872, the culture of jute in the United States has seemed to me to be a practicable undertaking. The possibility of introducing an industry whose annual product would stand next to cotton in fibrous importance is an agricultural problem of the highest moment. The observed conditions of growth in India are almost identical with those that exist in our Southern States. It is probable that Texas alone contains a larger area suitable for the cultivation of jute than that which in India is now yielding, annually, one hundred million dollars' worth of jute. The fibre has a high textile value. Its range of uses is almost illimitable. It enters into a vast variety of fabrics, from the coarsest cotton baling and gunny bags to the finest broadcloth and satin. Last spring Mr. Le Duc. United States Commissioner of Agriculture, kindly sent me several packages of jute seed. Some of it was distributed in the South and some was sent to friends in the city and neighbourhood of St. Louis. The seed given to Mr. Henry Shaw received no special care. It was entrusted wholly to the custody of Nature. The plants were not even watered, but they grew to a height of several feet and bore seed. The specimen of jute which was exhibited on 'Change the day before yesterday was raised by Prof. Jenks of Washington University. The following note explains its growth.

OCTOBER 22, 1880.

"The jute seed which you gave me was sown about the 20th of May in a compost of earth, coal-ashes, and horse manure, in a corner of my back yard which was shaded by a high fence nearly half of the day, conditions certainly not favourable to the fullest development of the plant. The ground was kept well watered. This specimen had attained a height of six feet three inches before the first of October.

"JNO. H. JENKS, 1418 O'Fallon-Street,"

Nothing but failure was anticipated from the trials in this latitude. The climate of St. Louis is too cold for jute. The experiments were tried with the hopeless motive of testing the hardiness of the plant. The result is an agreeable surprise. Its vigorous growth under circumstances so different from the conditions of its nativity, is a very favourable augury for the successful culture of jute in the Gulf States. A southern correspondent assures me that he can raise jute on his plantation just as easily as he can raise corn. The recent experiments being successful, the possibility of naturalizing this plant in the United States is now affirmatively settled. But American hands cannot complete with the cheap manual labor of India. In order to derive from this new industry a yearly return of scores of millions, the inventive genius of our countrymen must devise some cheap mechanical or chemical means of disintegrating the fibre.

Respectfully yours.
S. WATERHOUSE.

The Merchants' Exchange Directors, after considering the subject, adopted a resolution reciting that they had noticed with great satisfaction the experiment of Prof. Waterhouse in introducing the culture of jute in this country, and that from the results obtained it is evident that jute can be successfully raised in the Gulf States, and the board recommended the letter of Prof. Waterhouse to the careful consideration of planters and farmers in the South."

INDIAN EXHIBITS AT THE SYDNEY EXHIBITION.

THE following are extracts from Major Clementi's report .—

COCOANUT OIL.—Ceylon and Fiji showed far superior cocoanut-oil, which is a staple production now in the latter colony; copra also is largely exported from the Fijis. The cocoanut tree takes from five to seven years to mature in Fiji; about 50 trees are planted to the acre, producing about one ton of copra, worth on the plantation of £12-10. The export value in 1878 was £122,194.

INDIGO.—The judges had no technical acquaintance with this manufacture. Mr. James Inglis, who has the experience of an indigo planter, happening to be present when the judges came round, was able to explain to them the characteristics of good indigo. The result was a second award. I find that there are three dye establishments in this colony, but indigo finds no place in the list of colonial imports. Small quantities, of "indigo paste" are imported from England for the use of the dyers.

MATS.—These were very generally admired, and most of them sold. Nine were bought by gentlemen connected with the Belgian Commission, one by the Japanese Commissioner, and two by a Sydney resident. The rattan and grass mats received each a second award. Many persons thought that *khas-khas* screens would find a market here and in Queensland for use during the hot season. A living specimen, brought from Queensland of the *khas (Andropogon muriaticus)* was exhibited in the agricultural hall.

PITH HAT AND BOTTLE-COVER AND RAW—PITH.—Pith helmets and hats are very generally worn in this colony and in Queensland during the summer. The use of pith for bottle-covers was regarded as a novelty. The sample of raw-pith was much sought after by botanists many of whom specimens were given. Queensland exhibited a living, but, to very poor specimen of the plant *(Aschynomyne aspera)*.

CINCHONA.—There was nothing exhibited elsewhere at all equal to these specimens, which were considered remarkably fine and very interesting. The collection received a first award.

RED-WOOD AND CHAY-ROOT.—These exhibits were unnoticed excepting by collectors of botanical specimens. They evidently would find no market here

GROUND-NUTS.—These were so very inferior in quality as not to have been noticed. Fiji exhibited a variety of kinds, one sample being particularly fine. These, the Fiji nuts, fetch from £14 to £18 a ton. in bags, at Sydney. In 1878 about 444lbs. seem to have come to Sydney from Fiji for transhipment. The duty on all nuts is 1*d*. a pound.

RICE AND PADDY.—Long before the judging commenced, the raw rice and paddy were alive with insects. The rice trade is said to be falling off; the colonists are not rice-eaters. The following decennial statement may be given: In 1869, the imports were 2,621 tons; in 1870, 2,875 tons; in 1871, 3,561 tons; in 1872, 3,224 tons; in 1873, 4,982 tons; in 1874, 4,879 tons in 1875, 3,744 tons; in 1876, 2,578 tons; in 1877, 3,576 tons; in 1878, 6,080 tons; in the latter year the quantity of rice exported from Sydney was 1,866 tons, of which 15,568 cwt. went to Victoria, 2,881 cwt. to New Zealand, 8,245 cwt. to Queensland, and 8,953 cwt. to New Caledonia. No rice is returned as imported direct from India, but in 1878 1,515 tons came from Victoria, 2,002 tons from Hong-Kong, and 2,141 from Japan. The Patna rice seems to be best liked in this colony; the greater quantity of rice by far is imported for the Chinese colonists, who are increasing in numbers. Since the opening up of the Torres Straits route, the Chinese dealers have imported China-grown rice which is cheaper than the Patna, though it seems that the Chinese would prefer using the latter kind if they could be supplied with it by the Sydney-Chinese importers. The duty on rice imported into Sydney is 60s. a ton. In the Queensland Court Mr. A. Macpherson exhibited samples of various kinds of rice grown by himself in Brisbane, and gave me some of each kind to try. The grain was small and badly dressed, but, when cooked, some of the samples proved to be of very good quality. Mr Macpherson informed me that he found the rice he sowed on dry land produced as much straw and grain as that sown on swampy ground; but in Queensland there are heavy dews and occasional rain. The produce of one-eighth of an acre Mr. Macpherson found to be £428 or 68 bushels, or £50 to the acre. His interesting pamphlet, giving the results of his experiments, will be found among the publications accompanying this report.

MADRAS GRAM.—This description of grain is not known here. Like the other grain exhibits it was full of weavil by the time it was looked at by the judges in class 623, and they passed it without a word. It happened, however, that this grain was also judged in class 627 (seeds and seed-vessels), the judge being Mr. J. Inglis, late of India, and he reported it as being an exhibit of "very fine gram-seeds." On my bringing this to notice, the Committee of Judging and Awards decided that the exhibit should be placed in the third degree of merit.

TOBACCO LEAF.—These exhibits, as compared with the samples from elsewhere were considered to be of not much merit. With some hesitation the judges awarded the Madras exhibits a fourth place in the order of merit.

CIGARS.—There were a few inquiries for these, and I gave samples to those wishing to try them; but they were not as a rule approved of. The judges took away samples of each sort, and in the end declined placing them in any order of merit. Owing to the imperfect protection afforded by the show-cases, by far the greater part of these exhibits were pilfered It is thought here that Indian tobacco will not find a market in his colony.

TEA.—Very great interest was taken in these exhibits. Japan exhibited some very good samples of Pekoe Souchong and Congou of which I have kept samples; and Ceylon exhibited a large number and variety of very excellent teas; China did not exhibit. The judgment was by courts and not general as it ought to have been. The results of the judging cannot be considered to be satisfactory all my endeavours to obtain a fair and intelligent judgment having been thwarted. Mr. Ponder was really the only one of the judges that had a technical knowledge of tea, and he was appointed on my nomination, as I could not find any one else not exhibiting who had the experience of a professional tea-taster. But as he was engaged at the time in the business of a Sydney merchant, the agent for three exhibitors who were the Calcutta agents for a number of tea concerns I considered that great caution was necessary, so that the judges should not know the names of the exhibitors of tea concerns until after they had given their judgment on the merits of all the teas, variety by variety. The Government of Madras exhibited 24 samples including nine varieties, and received a third award. These teas were exhibited in shallow boxes, divided into 12 partitions each, with small pieces of glass, one for each partition, slipped in one over the other. This was by no means a good plan, as the least vibration caused the glasses to slide, and, even when properly adjusted, the teas were exposed to dust and air, as there were open spaces where the glasses overlapped. Mr. W. Lee Kirby, Brooklands Estate, Nilgiri Hills, received a second award for the six varieties exhibited by him. Messrs. Begg, Dunlop & Co., exhibited 18 samples, which included seven varieties of tea, and received a first award for the collection; the teas were well shown in large glass bottles arranged on a stand—in my opinion not only the most convenient, but the best way of exhibiting teas. The two varieties exhibited by the Commissioner of Arakan received no award, though they were surely samples of no common merit. The Singbulli and Murmah Company exhibited three varieties and four samples of Pekoes, receiving a first award. For the collection of 35 samples, which included 11 varieties of tea, a first award was adjudged to Messrs. Williamson, Magor & Co., whose teas were well shown in large glass bottles. The Kousanie Tea Co.'s exhibit included eight varieties of very high class teas, possibly equal to any shown, but they only received a third award. The six varieties shown by the Muka Ruttyoor Tea Concern were unsurpassed by any other exhibits, yet they were adjudged only a fourth award. Messrs. O. Steel & Co. sent down three varieties of teas in 14 varnished teak-wood chests, of which a trophy was made in the Indian Court, glass being let into the front of one chest of each variety. The Company received a fourth award. The teas of Messrs. Balmer, Lawrie & Co., were well exhibited by their Sydney Agents, Messrs. Clifford, Love & Co., in a handsome show case. There were nine varities of as good tea as any shown, but they received only a second award.

COFFEE.—The judging here was as unsatisfactory as it was in the teas. In sending down samples to the judges' room, I followed the same plan adopted in the case of the teas. The awards were, however, given for collections, and not for the best of each specific variety. The judging was general and not, as in the case of the teas by countries or courts. Thus an exhibitor from New Caledonia received the only first award for coffee beans as being the best in the exhibition, and for the same reason a Fiji exhibitor was adjudged, the only first award given for parchment. The award to New Caledonia was so manifestly unfair that the Commissioners for Ceylon and Fiji joined with me in appealing against it. I have kept a sample of the coffee, which is unsized and of every variety of colour. The Committee of Judging and Awards declined to alter the award. The awards are as follow: To Messrs. Parry & Co., a fourth award for coffee beans, to Fairlands Estate, a third award for parchment and coffee beans; to Messrs. Staues & Co., a second award for the Hullacary Estate coffee beans, and a third award for coffee beans from the Colacumbay Estate; and to Mr. J. Lechler a fourth award for coffee beans. The coffee-planting in Fiji promises well; some really excellent samples were shown. The first crop, at two years yielded about 400 lbs. the acre; last year over 1,000 acres were under crop. The coffee grown in New Caledonia is nearly all consumed there, and she imports a good deal. In 1878, for instance she imported from Sydney 22,507 lbs. Her coffee is said to be, as a rule poor and weak, and of bad colour, though some is reported to be of very good flavour. The Adulteration Act is not put in force in Sydney, so there is considerable adulteration practised. The grocers buy the coffee sometimes raw, but more generally roasted, from the importer, and adulterated it with chicory before retailing it, more or less as the wholesale price rises or falls. Ceylon plantation No. 1 is the kind of coffee in principal demand. In 1878 the amount of coffee on which duty was paid for home] consumption was 448,856 lbs; whilst of chicory the amount was 304,546lbs. The duty on both articles is the same—3d. a pound. In bond

the price of Ceylon plantation coffee is from 11½d. to 1s. a pound, and its wholesale price when roasted is from 1s. 6d to 1s. 7d. a pound. The grocers keep two qualities as a rule, which they sell, according to the amount of adulteration, from 1s. to 2s. a pound.

SPICES.—These exhibits did not attract much attention and received no award. Chillies are largely grown in these colonies.

CONDIMENTS, PRESERVES, &c.—Many of these exhibits were favourably regarded. Those of Nujeeb Khan & Co. Sydney Agents, Messrs. Clifford, Love & Co., were exceedingly well got up and well displayed; they were adjudged two first awards and one second award. The exhibits of Vencata Chellum, Sydney Agents, Messrs. Lorimer, Rome & Co., were large and various; they received one first, two second, one third, and one fourth award. This class of comestibles does not find any large sale here, being possibly too expensive for the general run of colonists; a better sale is found in Queensland.

COIR YARN.—The coir from Fiji was thought by the judges to be finer than that from Madras. In 1879 New South Wales imported 6,152 bales of fibre from Fiji, and 6,572, bales in all. There is no duty. I understand that cocoanut trees are now being extensively planted in N. Queensland. The Madras aloe fibre and *sun* hemp were considered good in quality, and were adjudged each a second award.

AGRI-HORTICULTURAL SOCIETY OF INDIA.

The Annual General Meeting was held on Thursday, the 13th January 1881.

W. H. COGSWELL, ESQ., *Vice-President, in the Chair.*

THE proceedings of the last meeting were read and confirmed.

The Report from the Council was submitted and adopted. The Report enters first into the internal economy of the Society, shewing that after deducting deaths, resignations, and departures from the country, and allowing for elections during 1880; the total real number of paying members on the books is 471 or 14 less than last year. The report adds that the financial position is much the same as last year; although there has been a decrease of expenditure in some items, there for has been an increase in others, which nearly equalizes the account.

The report then proceeds as follows :—

"It will be observed that among those who have been removed by death is Mr. John Scott, Curator of the Royal Botanic Garden, Calcutta. Mr Scott, was the contributor of several valuable papers to the Journal, among them "Notes on Horticulture in Bengal" and "a list of the higher Cryptogams cultivated in the Royal Botanic Garden, Calcutta," and several other minor papers. Mr. Scott was always ready to assist the Society on all subjects referred for his consideration. With an observant and original mind in him was united great modesty and unobtrusiveness of character. He was elected an Honorary Member in 1871. His death in the prime of life is not only a great loss to the Society, but also to Vegetable Physiology, of which he was an ardent and able votary.

The Council have also to allude to the loss sustained by his departure from India during the year of Sir Louis Jackson, C.I.E., late President of the Society. In the Proceedings of the General Meeting in May, in which Sir Louis' letter of resignation was submitted, will be found the resolution of the Society expressive of their "warm appreciation of the interest he has taken, and the valuable services he has rendered, in dealing with the various subjects that have been under consideration during his four years' tenure of office." Sir Louis Jackson was, at the same time, unanimously elected an Honorary Member.

The annual shows of vegetables, fruits, and flowers were held as usual in the early part of the year,—that for the former in the Town Hall on 29th January, and the latter (flowers) in the garden on the 16th February. The vegetable show was an excellent one, perhaps, the largest, or one of the largest, held during the last forty years. The flower show was also about equal to those of former years, and the attendance was large. It was found necessary, in the interest of the market gardeners, to hold the show of vegetables and fruits separately instead of, at one time, as heretofore; and in the forenoon, instead of the afternoon, to allow of their selling the produce immediately after the closing of the exhibition.

Vegetable and flower seeds were imported as usual, and widely distributed. There have been many complaints in respect to the flower seeds which may be mainly attributable to the adverse season in England of 1879 for ripening seeds. It is proposed in future to order a more select assortment of flower seeds, consisting of those that are known to succeed well in Bengal and Upper India, and to increase the quantity of each. It is hoped this will afford satisfaction to the majority of Members.

In respect to the Garden, it may be noted, that the distribution of plants is gradually increasing, as their privilege of indenting on it annually is becoming better known to Members. Applications (250) for delivery orders have been duly met; besides many (80) supplementary orders. Of ornamental plants, 9,350 have been distributed to Members, besides a quantity of economic plants and cuttings. In addition thereto, there have been sales to Members and the outside public, of 1,440 fruit grafts, and 1,212 ornamental plants. To increase the stock of roses, for which the demand continues greater than for any other class of plants, supplies have been received, by exchange, from the public gardens of Allahabad, Agra, and Lahore. A consignment from Mr. Bull of Chelsea, arrived in the early part of the year unfortunately in a totally unserviceable condition, scarcely one alive. A subsequent consignment in November reached in excellent condition. The demand for economic plants, Mahogany, Coffee (Arabian and Liberian) Pithecolobium saman, and certain timber trees, has been constant. The supply of these is still great, while of ornamental plants the stock is also large, notably of Crotons, Palms, Dracænas, and a few other kinds of variegated foliage. The collection of fruit grafts, especially of Mangoes of many kinds and of Lychees, is now sufficient to meet a fair demand.

The contributions to the Garden have been as great as last year. The Society is especially indebted to the Queensland Acclimatisation Society, Mauritius Botanic Garden, Calcutta Botanic Garden, the Baron F. Von Müller, Messrs. C. Ady and Rowett of Rangoon, C. K. Hudson, C. Nickels, E. H. Man, Dr. R. Beaumont, Col. W. M. Lees, and Capt. J. F. Pogson.

The attention of the Society was called by the Government of Bengal in the early part of the year, to the desirability of trials with certain kinds of manures on certain crops in connection with some recent experiments at the Bangalore Farm. The Garden Committee took initiatory steps towards meeting the wishes of Government, but being unable to undertake the trials in the manner suggested, have deferred doing so for another season, when they hope to carry them out as fully as the means at their command will admit.

Trials were also made at the commencement of the rainy season with several newly manufactured ploughs submitted for competition. The report of the Committee will be found in the *Proceedings for July.*

There has been a fair demand throughout the year for seeds of useful kinds, other than vegetable and flower, and many applications for information on various subjects; all which have been complied with. Notices of some of these are recorded in the monthly Proceedings. In addition to these, certain papers of interest have been submitted regarding cotton and cotton seed oil, tobacco, fibres of sorts, &c., which have been discussed and reported on.

The Council cannot close this brief summary without reiterating what has been more than once urged in previous annual reports, that unless they have a more hearty co-operation from Members generally, resident and non-resident, they cannot expect the operations of the Society to be conducted with that success which characterized it, proceedings in former years. It was by the united efforts of public-spirited men that the Society was founded, it is mainly by a continuance of such efforts that its influence and prosperity can be maintained. It is true that times have changed,—that European Society in India is becoming annually more fluctuating, many considering themselves merely birds of passage. It is, moreover, the fact that competition in all branches of life—public and private—has become greater; that Europeans have not the same amount of leisure that was possessed by their predecessors to render such assistance as could be desired to public institutions. Still, notwithstanding these drawbacks that may be existing, if those who are interested in the Society's work (and it is but reasonable to suppose that some really are) would annually induce one or two friends to join it, the number of subscribers would soon be considerably increased. With such increased numbers would come increased influence and increased power for useful work, of which it may be added there is much before us, if we possessed the necessary means of application.

The Council regret also to observe that while the spread of education is rapidly increasing in this country, the landed proprietors and other intelligent natives, Hindu, and Mahomedan, have not as yet, with few exceptions, shewn that interest in the Proceedings of the Society which might naturally be expected from a class who would derive most benefit. Such was not the case in former days when the leading members of the native community, not only took an active part in our proceedings, but contributed to its transactions. They do not now number even one-sixth of the entire list.

Since the issue of the last Report only one number of the journal has been published, Vol. VI, Part 2. Another is now in the press, and will be distributed in the early part of this year. The Council would also request more assistance in this department. We have, indeed, competition here again, where formerly we had the field almost entirely to ourselves. Nevertheless more might be done than has been recently effected. We should ask not only Members, but the public in general, (Zemindars and other Agriculturists) who are favourably situated, to co-operate in this line. Let each contribute his item, however apparently unimportant it may appear to be, of sound practical information, founded on facts, the result of his own experience, and we shall be enabled to publish annually a much larger number of useful papers, and be in a position to disseminate them more frequently for general information, and thus confirm the words of the founder of the Society, in his opening address, some 60 years ago—that "a body of men engaged in the same pursuit from a joint stock of their information, and thereby put every "individual in possession of the sum total acquired by them all."

The election of Officers and Council was next entered on with the following result :—

President.—Mr. W. H. Cogswell.

Vice-Presidents.—Baboo Peary Chand Mittra, Mr. S. H. Robinson, Mr. G. L Kemp, and Baboo Joykissen Mookerjee.

Secretary—Mr. A H. Blechynden.

Council :—Mr. J. E. MacLachlan, Mr. R. Blechynden, Dr. G. King. Mr. H. J. Leitch, Dr. S. Lynch, Baboo Protapa Chundra Ghose, Mr. W. Stalkartt, Rajah Suttyanund Ghosal Bahadoor, Mr. J. G. Meugens, Mr, A Wilson, Mr. W. Pigott, and Mr. H. A. Firth.

The names of Mr. Cogswell, and Baboo Bholanath Dhur were added to the Sugar Committee, and Mr. J. G Meugens, to the Tea Committee.

The names of the following gentlemen were submitted for Membership.

C. Duke, Esq., Assistant Commissioner, Engatein, Rangoon,—proposed by the Secretary, seconded by Baboo P. C. Ghose.

Bhupendra Bahadoor Sing, Rajah of Kuntil,—proposed by Mr. W. G Jackson, C.S, seconded by the Secretary.

W. Martin, Esq, Indigo Planter, Myupoory,—proposed by Mr. J. Thomas, seconded by Mr. R. Blechynden.

T. J. Kallonas, Esq., Indigo Planter, Mymensing.—proposed by the Secretary, seconded by Mr, J. E. MacLachlan.

Rejoined.—T. Allen Brown, Esq., Deputy Magistrate, Agra.

The following gentleman was proposed, on the recommendation of the Council, as an Honorary Member :—

T. Lewis Bernays, Esq., Vice-President Queensland Acclimatization Society.

MINERALOGY.

MR. WYLD, (Geographer to the Queen) of Charing-cross, will shortly publish an elaborate map of the Gold Fields and Gold Reefs of Southern India.

A COAL mine is reported by the Peshawur correspondent of the Lahore paper to have been discovered at Churi, near Campbellpore.

AN extensive coal-bed, estimated as capable of yielding 3,000,000 lbs daily for a century, is now being worked near Kisgashe, on the Kiou Kada, Japan.

THE Japanese Government, it is said, is going to develop the gold mines in the Island of Sado, which have as yet been worked very little. A large consignment of mining machinery, made in San Francisco, has lately been sent to Japan; and the Government hopes that systematic working will make the mines a success.

A SIAMESE paper says that there are rumours in circulation that gold has been discovered in one of the northern provinces of Siam, and that a rich specimen was recently brought to Bangkok.

A GOLD FIELD has been discovered at Temora, New Zealand, and the local Government have awarded the party of discovery £400 as compensation for their trouble, and as an encouragement to others to prospect the country.

THE Melbourne papers just received state that a nugget weighing 201 ounces, and worth £800, has been found in some alluvial gold workings near Inglewood in Victoria.

ITALY has struck oil. Petroleum has been pumped in the Abbruzzi and in Piedmont; companies are being formed to sink and work more wells, and exports from Canada have been sent for to supervise the extraction and refining of the oil.

THE Society of Arts is showing some interest in Indian gold-mining. During the session which has just commenced Mr. Hyde Clarke will read a paper on "The Gold Fields of India," and Mr. A. G. Lock one on the "Causes of Success and Failure in modern Gold Mining." Both lectures, from the ability and reputation of the lecturers, will be read with interest.

THE *Ceylon Times* lately asserted that gold had of a certainty been discovered in Ceylon, the Editor of that journal stating that he had seen a small nugget. "Raglan" writes to the paper, asking for further informatoin, and the editor replies:—

That there is gold in Ceylon, there can be no doubt: this as we stated, was proved to us. We are not at liberty to state where this gold was found, but we can say, and on the best authority, that on investigation it is found that it is in such very small and unappreciable quantity as to preclude any hope of profitable collection.

We learn that the locality in which the nugget was found, has not rewarded further search save in demonstrating that the place is rich in precious stones of good quality: two rubies have been found equal in richness of color to any stones from Burmah.

SOME 50,000 tons of Australian copper were shipped to Calcutta last year, *viâ* England, instead of direct. An explanation is found for this in the difficulty of making satisfactory financial arrangements between India and Australia. The Lieutenant-Governor of Bengal hopes that the growth of a direct trade with Australia in tea, jute, seeds, and other Indian produce, will in time correct the anomaly. It is a hopeful sign that India sent over twelve million gunny bags to Australia last year. The total value of the trade between the two countries was something over 70 lakhs, the value of Indian export being about 45½ lakhs, and the value of India's imports from Australia 24½ lakhs. An attempt to raise in Australia some of our next loan might produce good results.

GOLD IN BURMAH.

WITH the recent development of gold mining enterprise in Mysore and the Wynaad, would it not be as well if some attention were given to the gold washings in Burmah? At Shuaygyeen, the name of which signifies "gold washing," gold is even now found, and has been for years past, although not in very remunerative quantities. Mr. Theobald, of the Geological Survey, calculated some years ago that an industrious gold-washer at Shuaygyeen could calculate on making daily about five annas. A party of Chinamen tried their hands at gold seeking in Burmah about ten years ago, but the result was not remunerative, and, some of their number suffering from fever, they discontinued working. The time would seem to have come when further attempts should be made, and as gold undoubtedly exists in the sands of the Shuaygyeen river, the State might send a competent authority to this district to endeavour to ascertain where it is washed from. Besides gold it is known that lead, tin, copper, and galena exist in this district, and the services of a mining geologist might be spared for a few months in the year to ascertain if these mines might not be remuneratively worked. The last went there who came here in this capacity, Mr. Mark Fryer, was such an invalid that it was impossible for him to do justice to the work, which is arduous and has to be carried on under considerable privations. It is to be hoped, then, that the Government of India, if they send a mining geologist, will send a young man in good health, when there is, we think, little doubt that discoveries of considerable value would be made in the vicinity of Shuaygyeen.

FORESTRY.

WE see that Sir Richard Temple was to lecture before the Society of Arts last month on "Forest Conservancy in India."

KEROSINE oil has been put to a variety of uses. In Germany it is utilized for preserving timber with much success.

AN American agricultural professor recommends a paint of skimmed milk and brine (water) to render wood non-inflammable. It has the advantage of being cheap and durable, and is impervious to water.

RUSSIAN forests bordering on the river Dnieper have been destroyed so recklessly of late years that the neighbouring districts have become arid steppes, many of the most important feeders of the river having dried up. The amount of water in the river has largely diminished; rocks and sandbanks in its bed have been laid bare by the lowering of the waters, and the navigation is already interrupted. This is a serious disaster, as the river passes through nine districts and affects the prosperity of those provinces.

MESSRS. SHAW FINLAYSON & CO., of Calcutta are desirous of starting a saw-mill in the Upper Dehing Forest, and the Planters' Stores Company are going to establish one also in the same locality. Sir Steuart Bayley says of these:—

"The establishment of saw-mills, two of which it is hoped will very shortly be opened in Upper Assam, should create a demand for timber suitable for tea-boxes, and thus replace with indigenous produce, to the profit of the province, the present expensive and circuitous method of importing teak planks for this purpose from Burmah. Scarcity of local labour—not want of good wood for tea-boxes—is the sole explanation of the latter, and the mills, if judiciously worked, should do a good business.

IN his Burmah Forest Bill, Mr. Aitchison is resolved to take time by the forelock. Rangoon and Moulmein are the two principal ports of teak supply for India and the world. The chief sources of production are Upper Burmah, Siam, the Karennee country, and British Burmah. But it need hardly be said that there is no such thing as conservation in the trans-frontier territories; and the probability—perhaps Mr. Aitchison might have said the certainty—is that those foreign sources will in time be exhausted. In that case, and because the yield from the South Indian, Javan, and other forests, is insignificant, British Burmah will become the chief exporter, in which case the country's capability to supply the demand will depend on conservation. Hence the present necessity for a Bill such as Mr. Aitchison has introduced for consolidating, amending, and amplifying past regulations on the subject of the British Burmah forests. It is worth remarking the extent to which the export trade in teak has advanced since the annexation of Pegu. In eight years after the annexation, the exports were below seventy-seven thousand tons. For the five years ending 1879, the exports were upwards of one hundred and thirty-four thousand tons.

WE have repeatedly and at length called the attention of the Bureau of Forestry to the advantages likely to accrue from the results of afforestation in this country. We read in a foreign exchange an interesting account of the advance of that science in France:—"French forestry has accomplished wonders in France of late years. Wind-blown hill-tops have been covered with shrubs and trees, by building weirs in the mountain gorges and gradually cultivating vegetation upwards. The Torrent du Beurget is one of the best examples of this reforestation. In 1868 it was only a bare ravine of rocks. The torrent is now quieter, and has never since devastated the valley below with periodical inundations, as was formerly the case. From 1851 to to 1877, 68,000 acres were planted with trees, and 6,700 trees tufted, at an expense of 1,725,000 francs. The reclamation of sand dunes is accomplished by building strong fences and planting meadow grass, sedges, broom, or espartero grass in the lee of the masses formed by the shifting sands against the fences. The blue gum tree has been planted extensively in the South of France, and the marshes at the mouth of the Var have been drained, and the fevers that used to prevail there have been ended. In poorer soil the American oak has been planted.' If France can do so much in this direction, what might not we do if those interested were properly encouraged.

TREES IN TOWNS.

BEARING on the question of trees in towns, Dr Phené remarked as follows at the Social Science Congress:—"To the occupants of houses in streets having a northern aspect, the glare of reflected light is injurious but the effect would be much modified by the coolness to the eye produced by the green of trees. In ancient surgery, persons having weak or declining sight were advised to look at the emerald. In the old style of building, the streets being narrow, were both cooler, from the sun not being able to penetrate them with direct rays, and less subject to noxious exhalations from the scouring and purifying effects of the searching air to which narrow streets were subject, so that while there was no space for trees,

there was also less necessity. Wide streets on the contrary are hotter, and require the shade of trees to cool them, and as in the case of London, which has so far done without trees in its sreets, not only are modern streets compulsorily wide, but the enormous increase in metropolitan buildings renders every sanitary question one of importance; and the chemical properties of trees as shown by experiment, gives them an important standing on that ground, irrespective of ornament or the pleasure they produce. But that which is important in such localities is more imperatively demanded in poorer districts, on the score of health, as during the last year lone, 21,000 new houses were erected in London, producing four hundred treets with seventy-one miles and four hundred and sixty-eight yards of promenade."

ARBORICULTURE IN THE N.-W. P.

THE recent Report in the Arboricultural Operations in the N.-W. Provinces, though dealing almost exclusively with a comparatively small portion of the subject, the planting and maintenance of road avenues, marks a substantial step in advance. Aboricultural operations had previously been under the care of the P. W. D. Besides being necessarily limited to the planting and tending of road-side trees, the work had from various causes been hardly as successful as might have been hoped. It was in 1877 that Mr. Buck, recognising that arboriculture being one of the most important elements in the Agricultural stability of the country, was intimately connected with the agricultural Department, asked Government to allow him to undertake the control of district arboriculture. The arrangement was eventually sanctioned, but the year just finished was the first of real work. There are now, we find from the report, more than a hundred nurseries, with over a quarter of a million seedlings of selected species of trees, from among which some thirty thousand were planted out during the year, the operations being distributed over fourteen hundred miles of road. Care appears now to be taken that trees once planted shall not perish for want of subsequent attention; and excellent results have been obtained from a novel system of watering by means of the percolation of water from a common *ghurra* sunk level with the ground close to the roots of the tree. By this means the water is supplied directly to the root, while the soil surface continues loose and open, without the formation of that hard crust which is so prejudicial to the growth of young plants. The *ghurra* once filled, lasts three or four days, and no surface irrigation is required. The report contains an appendix which supplies in a few pages a series of clear and concise directions for raising, planting out, protecting, irrigating, and pruning young trees, with useful estimates as to the probable cost of these operations. Further, there is a list of all the more valuable trees, with notes on their *habitat*, modes of propagation, and the best methods to be pursued in their cultivation.

MR. BUCK ON TREES.

IT was in 1877 that Mr. Buck, Director of Agriculture and Commerce in the North-Western Provinces and Oudh, first offered to undertake the administrative control of district arboriculture. Up to that time the supervision had been entrusted to the Public Works Department. Mr. Buck made his proposals for the following reasons:—

"1. The nurseries at the different gardens were under his control, from which supplies of seeds and plants could be arranged and new and useful trees introduced.

2. He could superintend the system of thinning out of roadside trees, by which a fund could be created to meet a considerable portion of the expenditure.

3. He could exercise continuous supervision, so that the work of one officer who might take an interest in the subject might not be thrown away by the neglect of his successors.

4. Arboriculture, being one of the most important elements in the agriculture stability of the country, from the fact that trees counteract the fearful aridity of the climate in the hot months and supply vegetable manure from their decayed leaves, is intimately connected with the work of the Agricultural Department."

Even without an enumeration of special reasons, the suggestion was a most rational one on the face of it. The charge of arboriculture would have seemed more congenial and appropriate to a departmental chief whose business was agriculture, than to an officer whose *forte* lay in bricks and mortar, kunkur, and railway sleepers. Mr. Buck's plans were endorsed, but in a manner rather perplexing. A distinction was drawn between "arboriculture"—that is to say the planting of new avenues—and "maintenance of avenues"—that is to say old avenues. The former was made over to Mr. Buck, the Public Works Department continued to be responsible for the latter. But the question soon arose how long does it take a young avenue to grow old? The puzzle was as ticklish as the inquiry of the schoolmen into the number of angels that could comfortably stand on the point of a needle; and in course of years the problem might have set both the rival departments at loggerheads. Luckily, however, the P. W. D. gave it up, and the whole arboricultural work of the province was made over to Mr. Buck. His grant was at the same time raised from Rs. 17,300 to Rs. 85,000—a modest sum for the needs of the twenty-three thousand one hundred and odd miles of road in the forty-seven districts of the North-West and Oudh, to say nothing of the village and waste land plantations which the Director wished to make a beginning of, and the nurseries from which the road-sides and groves were to be supplied.

For the first year after the new arrangement, little was done beyond issuing instructions to the district officers. In the following year, operations were postponed till after the rains, so that the results recorded in Mr. Wright's report are more favourable than they seem. This, the first annual report on the subject, states that 1,430 miles of road were taken in hand during the year. One hundred and ten nurseries, exclusive of the establishments at Saharunpore, Cawnpore, and Lucknow, for the supply of seedlings are in working order. Only "trees producing food for man or cattle are allowed to be raised, or transplanted to the roads" Among the principal kinds reared are the mango, jaman, mahua, gular, pipal, babul, tamarind, and neem. Mere adornment has no charms for the practical mind of the Director; and even the siris, with its splendid but brief glories, has no place in his list of selected trees. In several localities, spaces have been set apart for groves, and supplied with seedlings: and instructions have been issued for beginning the same sort of work, on an extensive scale, in the Jhansi division. Less than Rs. 28,000, or more than four thousand three hundred rupees short of the full grant, was spent during the year. The balance lapsed to Government, "owing to the system not being in full working order, not because the full amount was not required. On the contrary, the grant is quite insufficient for the requirements of the forty-seven districts among which it is distributed, and many applications for further grants from officers, who may be trusted to see they are well spent, have to be refused." It appears that the arboriculture allowance in the North-West and Oudh amounts to less than half the sum granted for the same purpose in the Punjab. But if we are not mistaken, the North-West has the advantage as regards unity of management, and efficiency in the system.

As regards adornment, shade and ultimate effects on water-supply, the uses of arboriculture in arid countries like the Punjab and North-Western Provinces, are almost too obvious to require mention. We say almost, because it is surprising how people fail consciously to realize the share which the dreary monotony of their surroundings has in rendering their own lives dull. The utility of arboriculture in the way of improving the varieties of indigenous fruit trees has been less fully realized; but receives due prominence in Mr. Wright's report. We quoted the following sentences from his paragraph on the distribution of mango grafts:—

"The superintendents of the various gardens have had their attention called to the importance of improving the quality of indigenous fruits, and propagating superior species for distribution. Much attention has been paid to the mango, being the best and most common fruit in India; and arrangements have been made for the distribution among zemindars and cultivators of grafts of the best kinds at a very low rate. The system of inarching with small seedlings of the same year, brought to the notice of this department by Mr. Phillips, will, it is expected, prove of great service, as it reduces the cost of grafting, and, on account of their lightness, the freight in sending the grafts out. The selling price of each graft was formerly eight annas to a rupee. Now it has been reduced to two annas a piece. The net cost of each graft on this system is only half an anna. Difficulty, however, was experienced in obtaining a large number of grafts, for want of sufficient mature trees for inarching. The Canal Department was requested to allow their plantations in the Saharanpore district to be utilised for the purpose, and arrangements have been made for obtaining grafts in 1880-81. During the same year 5,000 grafts will also be purchased from the Khushru Bagh, at two annas each, and about 2,000 more will be raised at the Cawnpore Farm Garden. All these grafts will be offered to the public at two annas each, exclusive of freight, and they consist principally of the three varieties, the Maldah, Bombay, and Lengra. Another variety, the Fazli, considered to be the best in Bengal, will also shortly be imported. The district officers have also been asked to set aside a portion of every nursery established for permanent maintenance, which should ordinarily be planted with mangoes of the best kinds, in order to establish a stock of mature trees, from which to raise grafts in future years for distribution."

In connection with this utilitarian aspect of the subject, it may be mentioned that very successful efforts have been made in Gonda, Rae Bareilly, Muttra, and elsewhere, to induce zemindars and cultivators to plant trees, on the condition that they may use the fruit and dead wood. Well directed attempts of this sort will have the double advantage of popularizing the system, and enabling the department to prosecute the work at the smallest possible cost to the State.—*C. & M. Gazette*

GARDEN.

THE *Indian Amateur Gardener* is a handy little volume by "Landolicus," published by Messrs. Newman & Co. It is really fitted to be what it says it strives to be, the *multum in parvo* of the amateur gardener in this country, whether in the plains or hill stations of Northern India. It opens with a calendar for hill stations and plains, pointing out what is proper to be done in each month of the year. Valuable instruction is given on the subject of soils and manures, the want of which often causes so much trouble and disappointment to amateur gardeners. Within a brief compass it contains almost everything about flower and flower gardens which the ordinary amateur in this country needs to know, and which, without such a guide as this, it is so difficult to learn. The man who would not be entirely dependent on his *mali* should procure a copy.

THERE is promise of a glut of apples in the United States. The Boston *Herald* reports the crops to be the largest for many years, perhaps to the extent of 40 or 50 per cent. To June 30th, 1880, the shipments from Boston to England amounted to 173,379 barrels, of a money value equal to over £70,000.

THE apple tree, originally introduced from Europe, has spread in South America from Valdivia to Osorno, and even crossed the Andes into North-Western Patagonia, and thence eastward. Indeed, it has become so widely spread, and so general, that the Indians from the distant regions of the Argentine rivers, Rio Negro and Rio Colorada, are called Manzaneros, or Apple Indians. As a matter of fact, they and their kin in the provinces of Valdivia and Osorno live far more on the fruit of the apple tree than any European people, for it affords them both food and wine.

SHILLONG EXPERIMENTAL FARM.

THE Shillong Experimental Farm was given up during the year, and the Forest Department has taken over the orchard, with about fifty thousand of young seedlings of the wild apple (*Pyrus Indica*) which it is intended to graft for sale. Stock plants of good varieties were partly bought in Shillong, partly brought from Lahore and Saharunpur, and some from England. There is not much variety, and they ought to be increased so as to ascertain which varieties are best suited for the different attitudes and localities, as well as the different seasons. Apples and pears thrive admirably, and would, no doubt, become a considerable adjunct to the food supply of the people, if they grow them extensively, as they no doubt will do as soon as they understand sufficiently the advantages derived from the systematic cultivation of these fruit trees, a number of sweet chestnut trees are also in the orchard. One variety was raised from seed received from Europe, the other received from the Botanical

Garden at Saharunpur; the latter seems the hardier of the two. Different varieties of Peach, Nectarine, Apricot, Plum, Cherry, Mulberry, Medlar, Currant, and Raspberry are also cultivated in the orchard of Shillong, chiefly with a view to facilitate their extended cultivation in the province.

THE TULIP-TREE.

I AM anxious to place before your readers a few remarks recently supplied me, in a most kind and courteous manner, by Mr. Freeman, Caroll, Baltimore, in the United States, regarding his own experience in the cultivation of the Tulip-tree. Mr. Freeman states that some time ago, owing to the death of several young Tulip-trees, he planted others of the same kind in the month of April, and when the leaves were about two-thirds grown, about twenty-four trees were planted, and all survived. These plants, about 6ft. high, were taken from a bed of seedlings in the woods, whilst the dead ones had been procured from a nursery, and were considered to be very fine plants in all respects when planted the previous autumn. Mr. Freeman had just succeeded a gentleman in the position he (Mr. Freeman) occupied —very much more experienced and older than himself,—who had finished the autumnal planting, and he (Mr. F.) was assisted by an old man who had been in the place for years as a labourer. The latter told Mr. F. it would be utterly useless to try and remove the trees. His predecessor had often attempted to do so, but invariably failed. He admitted, however (a most important admission), that their removal had always taken place in the autumn, or the more expressive phrase "fall," as generally used in America. Mr F. cut back the head, and took off all long leaves, and planted them with merely ordinary care. The very best results followed—a fine growth was obtained the first summer. He has seen hundreds die when planted in the "fall," but not one when planted properly in the spring. He considers that owing to the spongy nature of the roots, they will not bear mutilation unless when active, which also obtains with magnolias. The plants removed by Mr. F. had not a particle of soil about their roots. He counsels me to use care not to let the roots become dry when out of the ground. I am so satisfied that Mr. Freeman's advice is sound and good, that I will take care in future never to plant a single Tulip-tree before April. I would beg, through your journal, to thank most cordially and respectfully Mr. Freeman for his valuable advice.—J. COLEBROOK in *Gardener's Chronicle*.

TEA.

WYNAAD tea as well as Wynaad gold is in high favour just now. Large orders have been received from Australia, and sample parcels sent to England are said to have given great satisfaction.

WE hear from Assam that owing to unremunerative working the past season, several tea gardens will be closed, and expenditure will be largely curtailed on many others. This will, of course, throw many planters out of employment.

A FLUSH was picked on a tea garden in the Dooars last week. In the hills, bushes at the lower elevations are beginning to send out buds, we are told.

VERY remarkable is the expansion of the tea industry in Ceylon. In 1875 one thousand four-hundred pounds were exported; in the past year the exports amounted to 81,492lbs.

WE see from Messrs. Watson's Tea Report of the 5th ultimo that the deliveries of Indian tea in London for the year ending 31st December last, were 41,000,000lbs., against 35,200,000 lbs in 1879; 36,700,000lbs in 1878, and 27,900,000lbs in 1877. The stock in London at the end of last month was 20,200,000lbs., and on the same date of 1879 was 17,800,000lbs.

MESSRS. CARRITT & Co. in a recent Market Report have the following concerning tea:—"The final reports received from the gardens show that our last estimate of 43 millions for export must be still further modified, and that, probably, not more than 41 to 42 millions will be available for shipment to Great Britain. Should the London deliveries during the next six months continue on the same satisfactory scale the new season's crop should, arrive to a favorable market."

THE season's export of tea to America from China and Japan promises to reach 83 million lbs. The yearly consumption in America is estimated at 65 million lbs., thus giving a considerable surplus over requirements, if consumption does not increase. Much of this increased supply will be in Japan teas, but China supplies are liberal.

A CHINA paper gives some facts about the tea trade with America for the current year, which disclose the following state of things. It calculates that the deliveries from China and Japan of all kinds of teas in America, for the year ending the 31st July last, amounted to 73,000,000lbs., whereas the deliveries for the previous year amounted to 60,000,000 lbs. From some detailed calculations our contemporary estimates that China and Japan can dispose of 80,000,000lbs. of tea to the United States during the present season. As the demand for tea in the States has not advanced in a corresponding ratio to the overwhelming supply, the conclusion is gathered that a very low range of prices is inevitable.

WE are glad to observe that the Tea Syndicate have decided to continue their operations with Australia for another season, and will also despatch an expert to America to obtain information as to the best means of opening up that market. Attention will also be given to Canada. By means such as these it is that the popularity of Indian tea will be increased and the future success of the industry assured.

IT is encourging to learn that Indian teas are rapidly meeting with the appreciation of the Australians. From the Melbourne papers it seems that much interest was shown by Australian buyers in the sale of the Calcutta Syndicate teas, and that a very extensive trade is assured for the present year. This result, it may be well to add, is mainly due to the wisely directed efforts of Mr. Sibthorp, the Australian Commissioner of the Syndicate.

WE hear that a company, or syndicate of some sort, is, or soon will be, in process of formation, for the purpose of pushing the Indian tea-trade in the markets beyond the North-West frontier. The markets are certainly there, but the difficulty is how to get at them. Something might be done if the Cabul Government and the great Chiefs, who are all but independent, would even negatively support the trade, by refraining from the imposition of exorbitant duties.

THE *Ceylon Observer* writes:—The cultivation of tea in Ceylon must be acknowledged to be a success when a planter is able to report the gathering in one year of 40,000lbs from 120 acres, 20 acres of which bore very little, the whole being under five years of age, and planted at over 5,000 feet elevation above sea-level. What is wanted now is . . . . some of the capital which is still so freely given to tea concerns in India. Ceylon, in our opinion, presents a far more favourable field than either Northern or Southern India for new enterprises in tea, in view of its many advantages of cheap transport, healthful climate, easily managed labour, and general convenience, apart from the very satisfactory returns of crop already realised in most districts.

THE *Ceylon Times* in an article on "the Australian tea markets" writes:—

The prices quoted by the Melbourne brokers for the various parcels of teas exhibited by Ceylon growers range from 1*s.* 3*d.* to 2*s.* 6*d.* per lb., the lowest price being more than has hitherto been obtained in London for any but one or two particular marks, such for instance as the Windsor Forest teas. It is evident that all the quotations given in the list to which we are alluding, are paying prices. There can be no reason why the quality of Ceylon teas should not with ordinary care be maintained at its present standard —the more useful qualities evidently being Souchongs and Pekoe Souchongs to sell at from 1*s.* 6*d.* to 2*s.* per lb.—the demand for higher qualities being limited, at any rate for the present. Time is required to show whether a demand may not be created for teas ranging above 2*s*; in the mean time it will be well that shippers bear in mind the injunctions of the Melbourne tea brokers in reference to the most suitable size of tea packages. There appears to be no doubt, that the most suitable parcels for the Melbourne markets are half chests of 38lbs nett weight, with superior qualities packed in half chests of 20lbs. each, and a few 11lbs. boxes. The reason given for this is the convenience of small packages over larger ones for transmission to the interior, especially beyond the lines of railway where in many casepack horses have to be used for transport.

THE same paper compares the tea districts of Ceylon with those, of India and observes:—

In the more suitable districts for tea where it is expected that from three to four hundred pounds of marketable teas can be produced per acre, there can be no doubt about profitable results to proprietors, even though growers in Assam complain that at this rate of yield estates are not worth carrying on. But Ceylon has advantages over the district of Assam and other outlying tea-producing countries of India, in not only a greater humidity of climate, but in cheaper labour and in far cheaper and readier transport. There is also this great advantage which Ceylon possesses over some parts of India,—that whilst according to Col. Money one of the reliable authorities on tea cultivation, the most suitable climate for tea in India is unhealthy as a place of residence for a man, our most productive districts for tea are also the most healthy as places of residence.

MESSRS. T. C. SILLAR have issued a chart illustrative of the history of the tea trade for a period of forty-five years. It shows the average monthly consumption and prices of tea since 1835, including the same particulars in reference to the Indian product since its introduction to England in 1859. It appears that the amount of common Congou imported has risen from 3,255,000lbs. in the former year to 13,500,000lbs. in 1880. At the same time the demand for Indian tea has grown from 100,000lbs. in 1860 to 3,400,000lbs. in the present year. By-the-by, we are told that certain private firms have anticipated the designs of the Calcutta Syndicate in diverting a portion of their Indian shipments to America. A belief is entertained in many quarters at home that the Americans could be made India's best customers, in the course of time, if Western tastes are a little humoured. While new markets are thus being sought for tea, a new grower is about to enter the field of competition. Southern Italy is to be a future tea country. A few years ago Count D'Amigo planted his farm near Messina with choice China tea plants, and these have thriven marvellously. The plantations are now to be considerably increased, and Signor D'Amigo is sanguine that he has struck out a new branch of agricultural industry for the south of Italy.

We observe that Karen hill tea is advertised for sale by a Rangoon firm. This is the first year any tea grown in Pegu or Tenasserim has found its way to Rangoon for sale. It is grown on the Karen hills near Tonghoo, and we believe that Mr. Petley, of the Bombay-Burmah Trading Corporation, is the gentleman to whose enterprise we are indebted for this new produce. There is one tea estate in the Arakan division, formerly owned by the late Dr. Mountjoy, Civil Surgeon of Akyab, which produces excellent tea, in no way inferior to the Assam varieties. If the Karen hill tea is equally good, there should be a large demand for it in Burmah, where, besides Europeans, the Burmese are great tea drinkers. At present they use principally low class Chinese tea, imported from Penang and Singapore by Chinese merchants, and sent by them all over the province, through their agents stationed in the principal villages for buying produce, hides, horns, ivory, cutch, and grain. These men, again, send the tea out in small ounce-packets by pedlars, so that there is hardly a place in the interior of Burmah where it is not possible to buy Chinese tea. If Indian tea-growers packed their teas in small ounce and two-ounce packets, they would be able to sell much more of it in Burmah than they do now, where the smallest package obtainable is a one-pound tin. This is too much for a poor man to buy at one time, and the Chinese, who know admirably how to consult the pockets of their customers, make it easy for the poorest of them to purchase a packet of tea at a cost of a few pice. Numbers of natives of India drive a lucrative trade by selling tea and coffee ready-made to the Burmese, in the streets, at a pice a cup. The mess is very weak, but it is hot, for the kettle containing it is carried about with a live charcoal fire underneath it, and the drink which is sweetened with plenty of coarse sugar is said to be greatly appreciated.

THE TEA SYNDICATE.

With reference to the doings of the Tea Syndicate which met in Calcutta last month, the *Englishman* writes :—

It will, no doubt, be satisfactory to the majority of those interested in tea to learn that the Tea Syndicate has decided to continue operations for another year, and further to extend their operations. We say the majority, because at the late meeting, when the question was discussed, one gentleman expressed an opinion, " that a continuance of the Syndicate operations would be taken as in opposition to merchants, who were desirous of undertaking the business, and he recommended that the operations should be closed, as far as Melbourne was concerned, and the attention of the Syndicate directed towards the further development of the trade with the other Colonies. If it were decided to continue the trade, he suggested that the Syndicate should place its supporters in the same position as merchants, by charging a commission equivalent to the charges incurred by ordinary shippers, for brokerage, commission &c., and that particulars should be supplied to merchants of the probable extent of the Sydnicate shipments, in order that the former might judge for themselves of the expediency of supplementing the Syndicate shipments." It was explained, however, " that the Syndicate principally represented the interests of producers, whose only object was the introduction of Indian tea to Australia and other places, where it is comparatively unknown at present, and that as soon as this object was, in their opinion, accomplished, they would be quite prepared to leave the continuance of the trade in the hands of merchants or others prepared to undertake it. No opposition was intended, and it was only a question whether the trade, although most successfully started, was sufficiently established to depend entirely on private enterprise for its successful continuance." So it was decided to continue operations with Australia for at least another season. The next question discussed was " whether it is desirable, or otherwise, to endeavour to extend the trade with America, through the agency of the Syndicate, and, if desirable, the measures which should be adopted to carry out the scheme." This was decided in the affirmative, Canada being included as well as America, and a resolution was passed authorising the committee, " if they shall consider it advisable, to procure the services of an expert in tea, thoroughly conversant with this market, who may be despatched at once to America with instructions to visit the principal places, and furnish the Syndicate with detailed particulars of the requirements of the trade in that country, so that the proposed operations may be conducted with fuller knowledge of the class of tea likely to be appreciated than could be obtained by ordinary correspondence with American firms, who have had little or no experience of Indian tea." In order to obtain the necessary funds to carry out this extension of their business, it was decided " that the Committee be desired to apply to Government for a grant of money, and empowered to take steps with reference to the introduction of Indian tea to America and Canada, so far as such grant, and the available funds from the balance of the subscriptions as yet uncalled up for Australia, permit, and to make such commission charge, if any, on all teas sent for sale through the Syndicate as appears to the committee desirable." Another important subject brought before the meeting was " whether it is feasible or not to form a combination among producers to regulate the monthly supplies of tea on the market next season by extending the arrivals from the gardens over a longer period, say ten months.' This, however, was not considered feasible, but it was said to be " the intention of several proprietors largely interested, to discontinue the system of bringing forward their crops so rapidly as had been done this year, and the subject is one well worth the consideration of the tea interest generally."

INDIAN TEA IN AMERICA.

A gentleman in New York who has been giving special attention to the subject and making inquiries relative to the question of the introduction of Indian tea into the American market, writes as below to the *Home and Colonial Mail*. It will be observed he states it as the opinion of the firm of brokers he consulted, that " Indian tea must eventually become popular in America," and that this desirable object would be " considerably hastened" by consignees sending teas suitable to the American taste, which he proceeds to describe. Shippers from this country should bear in mind too, that tea is admitted *free of duty* into America *when sent direct from the country where it is grown*. Some useful suggestions are given for the guidance of intending shippers to America But we will not anticipate further :—

"In America all Indian teas are called Assams. Various small shipments have been made to New York and Boston, but hitherto the introduction has turned out a failure, in consequence of the teas not being the grade required for these markets. The flavour of Indian tea, as a rule, is too coarse and strong for Americans, and as no tea—retailers in this country make tea a speciality, they do not understand, or will not undertake the mixing of teas, a method so well known and carried out in England. In New York, which I am told is a guide throughout the United States, tea it retailed as a " grocery"—a store where, in addition to groceries of all kinds, bread, milk, fresh vegetables, wine, beer, liquors, mineral waters, wood, and frequently coals, are sold. In fact, an American grocery is a combination of an English Italian warehouse—tea grocer, greengrocer, cheesemonger, and chandler's shop, with a dash of butcher and baker thrown in. You can easily understand from the foregoing why tea retailers do not understand the mixing of tea—it would cost too much time and trouble. There was another drawback against the success of these tea shipments alluded to—the packages were too large. The firm of brokers by whom I was given these particulars, were of opinion that Indian tea must eventually become popular in America, and the use of it would be considerably hastened by consignees, whether from England or India direct, sending teas suitable to the American taste. The consumption of tea in this country is already very great and continually increasing. The teas mostly used in the United States, and which have the readiest sale, are Oolongs, Pekoe flavoured Congous same as Assam tea, Formosa tea, and Japan tea. The latter is becoming popular, especially in Western States, where the water is so much impregnated with lime. There are also teas from the North of China, fine Pekoe Souchong flavour, that are well liked. Should any of your subscribers anticipate making a consignment of Indian tea, carry out as far as practicable the following suggestions. Select a crop of tea of medium strength, so that it can be used without mixing, and the flavour similar to the kinds such as I have told you are mostly used here. Have the tea put up in boxes, so that dealers willing to try it can buy small quantities at first by way of experiment. *Price*—to cost wholesale at from 50c. to 60c., per lb., say from 2*s*. to 2*s* 6*d*. sterling A shipment of tea can be consigned to any responsible house. The consignee would simply have to give instructions to a good firm of tea brokers, and they would furnish a report. This report can be cabled or written back. Tea is admitted to this country free, provided it is shipped from the country where it is grown. Should it be transhipped, say from England, there is an import duty of 6 cents per lb., equal to about 3*d*. sterlin'

COFFEE.

There has been, of late, a satisfactory increase in the quantity and value of Indian coffee exported. The value of the exports for the first half of the current official year considerably exceeded a crore ; the figure for the same period of last year being under 63 lakhs. It is a notable fact that more than half the total quantity exported went to France, where one gets good coffee.

Last year's Java coffee crop is estimated at about half that of the preceding year.

The Batavia *Dagblad* in a recent issue asserts, on the authority of advices from Mid Java, regarding the coffee crops, that the Hemileia fungus has done scarcely any harm to the coffee estates visited by it there. Hence this year's coffee crop in that quarter promises to be abundant, that of last year being short.

The exports of coffee from Ceylon for the past season are smaller than those of the preceding season, by probably something like 100,000 or 150,000 cwt. This ought to influence the prices for the better qualities of coffee in the home markets early this year.

A correspondent sends a Ceylon paper the original of the report furnished by a qualified chemist on White-weed Ash Analysis: —The ash yielded potash 21·57 per cent ; chloride of potash 4·1 ; phosphoric acid 5·24. This, remarks our contemporary, shews the serious demand made on coffee soil by the white weed.

Mr. C. S. Salmon, the Chief Commissioner, writes of Liberian coffee at the Seychelles :—" About 150 plants of Liberian coffee have been planted at Mahe Island at elevations varying from the shore to 1,500 feet above sea-level. It comes best, apparently, so far, in the open without shade. One plant at an elevation of about 300 feet without any shade, and close to a granite rock giving out considerable heat, has about 100 strong-looking flowers on it. This plant is eighteen months old."

THE ravages of the "leaf disease" among the coffee plantations of the old world, and of the "White fly" in those of the new, led planters a year or two ago to make trial of the Liberian coffee plant, which was first grown at Kew in 1872, and seeds of which were forwarded everywhere through its agency. The last report of Kew Gardens contains satisfactory accounts of its progress in such widely separate regions as Singapore and Dominica. It has not, however, proved altogether impervious to the "leaf disease," especially in Ceylon, while it is reported from Dominica that the "White fly," which had utterly ruined the old coffee plantations, has been seen to attack the seedling leaves of the Liberian coffee, although avoiding as yet the grown plants.

EARLY last month we were briefly informed by telegram that Mr. E. O. Schrottky had made some successful experiments in the cure of leaf disease in Ceylon. We now learn that his process is to cause the absorption of a chemical into the sap of the coffee tree by the cambium. The results of these experimental trials may be thus briefly stated :—It is shown that treated in its earliest stage of what are known as pin-spots, by the new process of inoculation the first germs of the newly-formed fungus may be destroyed, or at least their growth checked, as shown by the non-formation of the orange red dust or spores : consequently were it practicable to thus treat every tree on every estate, the fungus germs of the disease would cease to be propagated and the pest would disappear.

SINCE writing the above we learn that several agency houses have asked Mr. Schrottky to experiment on their estates, so that his supposed remedy for leaf disease will have a thorough trial. Mr. Schrottky himself is very sanguine of success, and should the results be favorable, it is believed that he will apply to the Dutch Government for the reward of £25,000 offered by them to the discoverer of a cure for leaf disease. A patent would also doubtless be granted in India and Ceylon.

IT appears, however, that Mr. Schrottky is not to have a monopoly in leaf-disease investigation. The *Ceylon Observer* just to hand states that "another agricultural chemist is now in our midst, in the person of Mr. Fretwell, an Indian Scientist, who has been for some years in charge of the Government Model Farm in the Bombay Presidency. Perhaps the news of Mr. Schrottky's experiments with our coffee pest, which was telegraphed to India some time ago, may have tempted his fellow scientist to pay our island a visit and see for himself what is being done."

WHILE Mr. Schrottky's experiments so far seem to have met with every success, it would be clearly unwise for planters to rush to any premature conclusions as to the ultimate efficacy of the new mode of treatment. It will probably have to stand the test of a whole season before it can finally be regarded as an unqualified success. Mr. Schrottky, we are glad to see, recognises this himself and the following extracts from a letter (dated 6th January) addressed by him to the *Ceylon Observer*, will be read with interest :—

. . . .

There is only one point that may possibly become of some interest to scientists if success continues, *viz.*, the absorption of chemicals in solution into the system of the plant by means of the cambium cells of the stem. I am not aware that even the possibility of such an absorption has ever been investigated by any authority. But that it can take place I satisfied myself two years ago, though at the time I did not even think the matter worth mentioning. I have no doubt that botanists will require some better proof than a mere assertion before they will accept this new theory, but based as it is on a well-known physical law regulating the movement of fluid matter in plant cells, positive proof will not be difficult. In the meanwhile it is practical results which we are watching for ; theories can wait. . . . .

. . . .

The data I have collected are far too few and incomplete to enable me as yet to come to a definite conclusion as to the merits, *if any*, of the treatment I have chosen as having, among a number of experiments (external applications and otherwise), held out the greatest encouragement. The results at Bellongalla as observed on the tenth day after treatment were certainly most encouraging, and I satisfied myself that a decided check of the disease had taken place on the treated area. But the great question is : How long will the benefit last, and will it enable the trees to withstand the appalling vehemence of the attack that is just now observable on estates around Kandy. The whole matter is still in its experimental stage, and I should wish, if possible, to avoid the great danger of coming to too early and then probably erroneous conclusions. . . .

THERE appears to be no end to the inventive genius of some people, and many of them seem to have made a "dead set" upon coffee. We have had the celebrated pelatos coffee, which was simply baked acorns ; more recently date stones have made their appearance in the London market under the title of *date coffee*. Yet another instance comes before us in the shape of a 'preparation of fruit,' under which name a foreign gentleman has obtained a patent for a preparation 'closely resembling Mocha coffee.' The fruit of the *Ceratonia Siliqua*, commonly known as carob beans or locust-pods, and vulgarly as Russian figs, is roasted and ground into powder, and is then mixed with a certain proportion of the roasted and ground seeds of *Vicia Sativa*, *i.e.*, tares. An infusion of this mixture may be used as a beverage, and if it is taken with a large quantity of imagination, it will closely resemble Mocha coffee.

MR. SCHROTTKY'S EXPERIMENTS WITH LEAF DISEASE.

THE *Ceylon Times* just received has the following brief but succinct account of Mr. Schrottky's progress so far, in the investigation and cure of leaf disease, by his new process :—

. . . . Mr. Schrottky labours with the advantage arising from acknowledge of previous failures ; he has also the great advantage that whereas his predecessor in experiments (Mr. Morris) was a botanist pure and simple, he has made agricultural chemistry his professional study for many years, and has been for a considerable period engaged by the Indian Government as their adviser in matters relating to the science which he has made his special study and pursuit

Our readers have already been made acquainted with the results of certain preliminary experiments on estates in Dolosbagie and Kaduganawa : those results are considered highly satisfactory, so much so indeed, that nothing is wanting to establish them as a complete success, but the certainty of the permanency of their effects. It may be said, no doubt, that this is precisely where the "lime and sulphur" remedy failed ; but it should be remembered that whilst that remedy consisted of an external application, the present process of acting on the organism of the trees by inoculation, is altogether an internal and constitutional remedy. Hence it is that those who are watching the present experiments with deep attention are hopeful that the effects will be of a permanent character. There is, of course, always this to be borne in mind, that a few acres of trees successfully operated on, when surrounded by some hundreds of acres of badly diseased trees, must inevitably incur a certain risk of re-infection, and hence it is that complete and thoroughly permanent success can scarcely be looked for until far more extended areas of coffee have been operated on than is at present the case. The estates recently experimented with have been Roseneath, close to Kandy, Pallikelle in the vale of Dumbara, and the Peradeniya Estate. As we are given to understand, the condition of the trees on the two latter properties was precisely such as was most favourable for testing the remedy, the disease having been in the stage known as pin-spots. Not so, however, with the first named : there, unfortunately, the pest was very fully developed, so fully indeed as to leave little hope of any real benefit being derived from the inoculation process. As a recent visitor to the estate described it, "the appearance of the red dust on the leaves throughout thee state was apalling, it was indeed as bad as it was possible to be." We think it right to mention this circumstance because, as it is scarcely probable that success will attend the operations on that property, failure should be attributed to the right cause. It may have been a knowledge of the condition of this estate which led a contemporary to state that success there would be decisive. It will, however, be quite sufficient for all present purposes that success attend the application on the two other estates. Mr. Schrottky makes no claim to miraculous powers, and he does not pretend to be able to effect a cure after the pest has passed the first or incipient stage of pin-spots, although it is quite possible he may be able to mitigate the severity of the attack. The results of the two experiments to which we have alluded, added to the confirmation of previous successes in other districts will no doubt enable the operator to feel far more confident in his process than he could hitherto pretend to be, and we shall hope that on his return from his present visit to the interior, with the results of the various experiments before him, he will feel sufficient confidence in what he has achieved to favour the public of Ceylon with a detailed account of his process and his own opinions upon it. We may mention that he has in the meantime, obtained provisional registration for the specification of his process with a view to secure complete protection by patent. To this it will be admitted he has a perfect right, and we feel sure the planters of Ceylon will not grudge him any benefits that he may derive from the successful application of his remedy, seeing how largely the coffee industry is interested in the successful outcome of his operations.

MR. MARSHALL WARD ON COFFEE LEAF DISEASE.

MR. MARSHALL WARD'S second Report on Coffee Leaf Disease has come to light. We regret we cannot, on account of its great length—and it is too important to be curtailed in any way—reproduce the Report in our present number, but we shall endeavour to do so in our next. Meanwhile we make the following extract from some comments of the *Ceylon Observer* on the paper in question. After remarking that the Cryptogamist deserves great credit for the care and devotion he has displayed in the conduct of the investigation, our contemporary proceeds :—

No one can read this Report without feeling that Mr. Ward is giving his best energies to the task before him ; and although the greater portion of the long document is of interest chiefly for its scientific information yet we have now, what was comparatively wanting in the preliminary Report, evidence that Mr. Ward does not ignore the practical and economic bearing of his investigation, but rather that he keeps steadily in view the object before the planters and the Government in arranging for the investigation, namely, the hope of discovering some feasible means of checking and mitigating, if not of extirpating the coffee leaf fungus. We must leave to scientific authorities any criticism of Mr. Ward's experiments and observations bearing on the diagnosis of leaf disease. It would, for instance, be specially interesting to learn the impression left on the minds of Dr. Thwaites and Mr. Abbay, and still more on those of Messrs. Berkley and Cooke, by the account given under the different sections of "pin-spots," "the second spores," the "filaments" (finally

pronounced to have nothing to do with *hemileia vastatrix*, a result which upsets Mr. Morris's "life-history"), and most important of all "the papillate spores (uredo spores)." Very interesting as well as eminently practical are many of the experiments described by Mr. Ward under these heads, as also in connection with "the action of the fungus on the cells of the coffee leaf," "the fall of leaves," and "the effect of leaf fall on the branches." Much light is thrown on various cognate questions which have higherto perplexed the planter in connection with the failure of his crops and "the insidious defunction" which marred and weakened his trees. The terrible drain on the coffee plant from the constant fall of leaves is most clearly illustrated with the aid of observations made by Messrs. Mackenzie, Anton, and Gabriel Ross in the Maskeliya, Pundaluoya, and Hantane districts, and we learn quite enough to shew that the persistent attacks of the leaf fungus are more than sufficient to account for all the deficiencies of crop, the disappointing appearance of the trees and many other evils (including possibly the liability to such enemies as "grub') experienced by the planter during the last ten years. "The fact must not be overlooked" (says Mr. Ward)—" and this point is of importance with respect to heavy manuring—that the continual renewal of leaf calls forth great energy on the part of the tree, and it no doubt follows as a direct consequence of this that the crop-producing capabilities of the tree are lessened." "At the same time" (to reverse the order of Mr. Ward's sentences in this case) "the marvellous power to reinforce itself that the coffee tree exhibits, may justly be insisted upon where other things warrant it; and *it seems impossible to doubt that the mitigation of leaf-disease would be followed by a rapid improvement in the crop-producing capacity of coffee.*" As we follow the various steps of this careful investigator, it is impossible not to be stirred by the hope of our being on the eve of important discoveries in connection with a tangible means of dealing with the planter's chief pest. Mr. Ward has commenced experiments with this end in view, the issue of which he is anxiously watching, and he promises to spare no trouble to thoroughly investigate and report upon the remaining phenomena of leaf-disease. The results of his experiments, as well as of those carried on under Mr. Schrottky's auspices, will be looked for with keen interest. But, meantime, curiously enough, Mr. Ward's one practical recommendation to planters exactly coincides with that most insisted on by Messrs. Morris and Abbay, namely the necessity of a thorough destruction of all fallen coffee leaves, as a certain source of propagation of the disease. Mr. Morris wrote :—

The most favourable season for the application of lime is just after a severe attack of the disease, say in September, October, and November, when the leaves have nearly all fallen. If quicklime is then applied it will destroy all the spores with which it comes in contact and by decomposing the withered leaves *in situ* prevent the danger of infection. The plan of collecting all the fallen leaves and burning them, which has been advocated as a precautionary measure with regard to leaf disease, is a good one if applicable to large estates, but I noticed that after a short time very few, if any, of the withered leaves under the coffee retain the spores upon them. The latter soon fall off and are found everywhere on the ground, where sooner or later they germinate and produce filaments which once more attack the tree. It is evident, therefore that by collecting the withered leaves and burning them; only a small proportion of the spores is destroyed, and taking into consideration the cost of collecting the leaves, the damage of a fire on a coffee estate and the probable scattering of the dry rip spores which must inevitably take place when the leaves are disturbed, I venture to suggest that it is much better to act on the old proverb, "to let sleeping dogs lie," and destroyed leaves, spores, filaments, and all with as little disturbance as possible by a plentiful application of quicklime. The value of the lime as a dressing for the soil, and the facility and ease with which it can be applied, are additional points in its favour.

As an alternative process, where it is not possible to apply lime to the whole of the estate at once the recently fallen leaves together with a little of the surface soil might be scraped together after a severe attack of leaf disease, into one of the numerous waterholes found on most estates, and covered over by a small quantity of quicklime. In this way a large number of spores and diseased leaves might be destroyed at a very trifling cost.

Again Mr. Abbay offered the following counsel :—

In more than one district it has been noticed that a strong wind has apparently had a great effect in carrying the "disease" up or down a valley, most probably by spreading the spores from some badly infected estate over the comparatively healthy ones. If such is really the case, the fact points to the conveyance of the disease, as suggested before, to the tree through the stomates of the leaf and not through the roots. It might be possible under such conditions to moderate the virulence of the pest in some of the more isolated districts if all the proprietors *would combine to gather and burn, at the commencement of the chief annual attack, all the diseased leaves and twigs that at present are allowed to lie on the ground beneath the trees until they decay.* Such a plan would no doubt be expensive ; but it would certainly destroy a vast number of spores, and might sensibly reduce the virulence of the "disease." The sprinkling of quicklime on the ground beneath the trees has, in one instance at least, proved beneficial ; and as it would no doubt destroy all the spores it came in contact with, it is not improbable that the two remedies, if applied simultaneously, might be found in some degree successful. The tree should also be washed with some suitable disinfectant, and the watering of the ground about the trees with the same disinfectant might possibly prove more beneficial than sprinkling with lime. It would be of little or no use for one planter in a district to attempt these remedies if the others did not—the spores produced on a single badly diseased tree being so enormously numerous, that a whole estate of healthy plants might easily be infected by a single unhealthy plant in their neighbourhood.

We earnestly trust that every planter in the country will now do his best to carry out this recommendation, or rather injunction, realizing the benefit which must result to himself as well as to his neighbours "The sweeping and burning of leaves" ought to be a work insisted on by all proprietors and agents of coffee plantations.

PANAMA A FIELD FOR COFFEE PLANTERS.

In the Consular Report on the trade of Panama (Columbia) the following appears :—"The main resource of the future wealth of this State would appear to be coffee. The high lands of Chiriqui, bordering on Costa Rica, are admirably adapted for coffee planting and have the great advantage over Costa Rican plantations of possessing easy communication with the sea ; coffee from Chiriqui reaching David, from which there is steam communication with Panama in forty-eight hours, by ox wagons, whereas from the coffee lands of Costa Rica to the sea is a journey of from seven to eight days, entailing, of course, a considerable expense for haulage and extra labour, and increased risks of loss and damage. Several immigrants from Costa Rica are now planting in Chiriqui. The trees are as yet young, but the samples of coffee produced are very good, encouraging the planters, and Colombia in general, to look with greater confidence to this new branch of Colombia's produce. The Government give a free grant to every settler of as much land as he can prove he is in a position to cultivate, and declare his plantation free from all taxes whatsoever for the space of ten years. There has been some trouble of late in obtaining legal titles to the soil, but an honest, unspeculative settler need not anticipate any such difficulty. Labour is cheap (about 1s. a day) and as yet is abundant enough for the demand. Women and children are chiefly employed for the picking, and at much cheaper rates. The laws are very favourable for the importation of foreign labour into the Republic. The climate of Chiriqui is pleasant, and in every way a healthy one, enabling Europeans to stand the labour with perfect safety. The best coffee lands lie from 2,500 to 5,000 feet above sea-level, with a temperature varying from 17° to 32° centigrade."

CINCHONA.

The necessary plant for manufacturing quinine on a large scale, will, we are told, be shortly set up at Mongpo.

CINCHONA cultivation is to be the subject of experiment in Italy, with a view to lower the cost of quinine.

JAMAICA is likely to become a serious rival to this country in the growth of cinchona, especially as regards the quality of the bark. We are told that about £5,000 net was realized for 27,000 lbs shipped to London in 1879-80, and the prices obtained were very much higher than for corresponding descriptions of Ceylon bark.

THE increase of cinchona cultivation in Ceylon within the past few years is very remarkable. In 1869 twenty eight ounces of the article were shipped to London ; in 1879 the total exports were 507,368lbs., and it is estimated that for the present year the shipments will amount to a million pounds.

THE quinine production of the world is estimated at from 230,000 to 260,000lbs per year as follows :—Germany, 56,250lbs. ; Italy, 45,000lbs. ; France, 40,500lbs. ; England, 27,000lbs. ; America, 63,000lbs. ; India, 12,250lbs. Efforts are being made to acclimatise the cinchona in Italy. Its successful culture in India and Ceylon encourages the belief that it will grow wherever the soil is dry, the rainfall large, and the climate temperate.

WE hear that the Government of Netherlands, India, lately deputed to Calcutta Mons. B. Moens, Director of Cinchona Plantations in the Island of Java, a gentleman of high scientific attainments, to make himself acquainted with the system of Cinchona cultivation in Bengal. Instructions were issued by the local Government to Dr. G. King, M.B., Director of the Plantation here, to afford that officer every information in reference to the cultivation of the plant that he may require in this country.

MR. JOHN HOWARD ON THE CULTIVATION OF *CALISAYA*.

(Concluded from our last.)

A VERY important reflection is that the cultivation is nevertheless remunerative and capable of easy and of indefinitive extension. The only chance for Indian cultivation in the future consists in the choice of superior sorts, and the efficacy of high cultivation. If these requisites are attended to, considering the greater facilities in India of conveyance to the markets, there is no doubt a great future open to both countries.

It will also be evident that there is practically no limit to the age up to which the *calisaya* may go on yielding serviceable bark. It does not change with age like the *succirubra*. This is owing to the difference in the tannic acid.

In Bolivia, as in Java—attention is paid to the effectual drainage of the roots. Mr. Ledger says,* "I think you should advise all parties forming plantations to plant on slopes or sides of hills. I have never seen the trees growing on flats or the bottoms of gullies. Too much damp at roots is fatal. Almost all the largest and best 'patches' of cinchona are found on red (dark) soil. The bottoms are black soil."

Examinations of a *calisaya* grown by Captain Cox in Wynaad, in the latter conditions, singularly confirmed to me this observation.

Mr. McIvor's experience led him to the same conclusion. He says,† after visiting Ceylon :—"The red and crown barks seem to do best in Ceylon as they do here. But on the whole our cinchona plantations on the Nilgiris give promise of better results than the Ceylon plantations. Ceylon is wanting in the deep rich soils we possess, and cinchona is very liable to canker when the roots get down into the subsoil."

I fear that this must be admitted to have been the cause of 'canker' in my *Calisaya Anglica* also. Perhaps in forming the bed, I did not pay sufficient attention to obviating this evil, and it is certain that one deep root found its way beyond where I could easily trace it.

* In letter, December 19, 1879.

† In letter to myself, March 16, 1879.

In a recently prepared bed I have at length effectually shut out the possibility of such mischief.

The following table * of the average prices obtained for the 100,000 half kilos of bark sent home from Java in 1878, will give a fair idea of the relative value of the different sorts there cultivated :—

Succirubra	1·75	per cent. per half kilo.
Calisaya Javanica ...	... 1·38	„ „ „
„ Josephiana ...	... 1·20	„ „ „
„ Anglica ...	... 1·58	„ „ „
„ Lodgeriana ...	... 6·31	„ „ „
Cinchona Hasskarliana	... 1·23	„ „ „
„ Officinalis ...	... 2·80	„ „ „
Cinchona lancifolia ...	... 1·59	„ „ „
„ caloptera ...	... 1·35	„ „ „
„ Pahudiana ...	... 1·10	„ „ „

By this it will be seen that the *ledgeriana* greatly exceeds all the others, and that it equals or excels the cultivated *calisaya* or Bolivia; but the average of this sort now sent will be much higher if I may judge from that now selling at Amsterdam.

I wish this remark, however, only to apply to the true *ledgeriana*, for which as much as 15s. per pound has just been paid at Amsterdam; but in packages recently bought under this name I find sample at a lower price exactly reproducing the finer *calisayas* of which I have been treating; but containing not more than half the quinine of the *ledgeriana*.

I have examined the *officinalis* bark from the same sale, and find that it resembles in appearance the "knotty sort of Jussieu" It has no reference whatever to the true *C. officinalis*. I am persuaded that this (the *uritusinga)* has never found its way to Java. In all that I have seen from thence and in the excellent botanical specimens given me, I find the *angustifolia* indeed, but no trace of the *uritusinga*.

The important question of the relative proportion of supply to demand will gradually enforce upon the planters the necessity of cultivating none but the best species. I have long been insisting on this point both as to the cultivation in Java† and in India.

The prospects of the future in Ceylon are almost alarming, at least if we may trust the calculations of Mr. Dobree, Dikoya. Ceylon; published in the *Ceylon Observer* of June 15th, 1880. He says :—

"I see by your Directory of 1876-78 that you estimate the total consumption of cinchona bark for the world at 12,621,000lbs. In Dikoya and Maskliza districts alone, during 1880, I believe I am under the mark in saying that there will be 6,000,000 cinchonas, exclusive of those planted in previous years.

"Nearly every other district in the island is also planting cinchonas; and I do not think I am over-estimating the number of cinchonas that will be planted in 1880 throughout the island at 20,000,000; allow 5,000,000 for failures, and add 5,000,000 for plants, in previous years and now alive, and it will give you 20,000,000 cinchona trees, which in five years will yield either by taking strips, or mossing, or by the shaving process, about 10,000,000 lbs. of dry bark a year.

'Again referring to your Directory, I see you estimate the production of cinchona bark for the world at 13,471,000, of which Ceylon is put down for 150,000; but when it produces 10,000,000, as I believe it will, in 1885 the total production of the world will exceed the demand of 1876-78 by 10,847,000lbs."

It is proverbially uncertain to count one's chickens before they are hatched, and, considering the enormous mortality overtaking the plant (occasionally, if I mistake not, amounting to 90 per cent). I think the above calculation far too sanguine; but, supposing it is correct (for argument's sake to the extent of one-half the estimate, I think I foresee one result. I do not choose to predict—as I never like to do this unless I am sure that my predictions will come to pass—but I think I may fairly anticipate crowded sales-room in this market in 1885, at which the representatives of various quinine manufacturers are attending, with the portentous word "rubbish" as a pencil note attached to certain vast consignments of Ceylon bark.

For proof of the probability of this anticipation, I refer to the account I have given of the whole of last year's importations in the *Gardener's Chronicle*. No doubt much good and profitable bark will also be imported (as is now the case) from Ceylon, and probably this will keep up its price, or nearly so. Dr. Trimen informs me that he has two new plantations of *ledgeriana* under his care, which are looking very well at present. Abundant information will be found in the *Ceylon Observer*‡ as to the successful efforts of private planters, on which I must not enlarge; but remark by the way, that renewed *officinalis* bark from prospect estate on the Nilgiris, lately sold as high as 12s. 6d. per lb. This was from the true *officinalis* defined and published as such by Sir Jos. Hooker, and well described since in Bently and Trimen's Medicinal Plants.' It is the *Uritusinga* of the 'Nueva Quinologia' of Pavon and this name was retained by McIvor, from whom (before his lamented death) I received excellent specimens grown under his care. It is at the present time flourishing with me, and deserves no doubt the description given by a planter§ as being 'the largest leaved variety of the true *officinalis*.'‖ I have leaves up to 9 inches by 6. I observe with pleasure that this writer (W. E. L., of Loangapilla, Ranjala,) says, 'I think it by far the most profitable kind to grown in Ceylon.' No doubt both this and bark properly renewed from *C. succirubra* will always command a good price in the market, as being rich in produce of alkaloid suited to the quinine manufacturer.

On the whole I think it is evident that the true *calisaya* will assert its supremacy as the prince, or, as I should call it, the queen of all the cinchonas. Such indeed is the import of its name as 'the best of all barks' for the production of quinine. It is also quite clear that we are as correct in ascribing to Mr. Ledger the introduction of the unrivalled *ledgeriana* as we are in speaking of Columbus as the discoverer of America. Mr. L. has the merit of employing the accurate discernment of his faithful Indian servant for collecting the very best seed; and in this he has shown the importance of knowing how to employ and to trust good subordinates—a secret of success in other enterprizes than that of the cultivation of cinchona. It is not by evolving theories out of our inner consciousness, but by patient observation of facts, and following out deductions from these to their legitimate results, that the cultivation of *calisaya* can be advanced. In this way Mr. Moens has the credit of introducing several improvements, which it would prolong this paper to too great a length to describe. I would simply mention the raising of the seed in porous earthenware pans, the subsequent care requisite to be extended over the young plants, the grafting of the *ledgeriana* on stocks of *succirubra*, and the mode of harvesting the bark by scraping. On this latter point I will remark that it is not in the *calisaya* that we find the striking preponderance of quinine in the outer bark, which I believe I was the first to demonstrate in the face of many authorities to the contrary. In the scrapings of the *calisaya*, so far as appears at present, there is not a greater abundance of alkaloid than in the bulk of the bark. The reason for this is in the difference of microscopical structure between one variety of cinchona and another. I have shown how remarkably this is changed in the renewal of bark of *succirubra*. The "lax cellular tissue" thus formed is full of alkaloid throughout its whole extent. The whole nature of the bark is thus changed.

SERICULTURE.

THE Government of Madras has issued a memorandum, through the Revenue Department, to Collectors especially, that as there is an extensive and increasing demand for Tusser silk in Europe, chiefly in France, speculations in this article are likely to prove very remunerative to persons embarking in the enterprise.

THE quantity of raw silk shipped from India in the year ending April 1, 1880, was 563,210 lbs., valued at £458, 505; of chussum or waste silk, 788,481 lbs., value £53,017; of cocoons, 49,815 lbs., value £4,604; thread for sewing, &c., 162lbs., value £132. Silk piece-goods 2,203,971 yards, value £217,893; silk fabrics mixed with other materials, 130,133 yards, value £10,474. The import in trade is considerable. In the year, 200,502lbs. of raw silk, valued at £683,235, were received; 466 lbs. of silk-thread for sewing, value £1,337; 7,467,815 yards of silk fabrics, value £765,583; 1,035,643, yards of goods, of silk mixed with other materials, value £70,393, and other sorts of silk, value £576, making a total value of silk manufactures imported £837,890.

TOBACCO.

TOBACCO culture in Italy is coming into notice, and vigorous efforts are being made to increase the growth of the plant.

TOBACCO yielded a full crop in Rungpore, last year (1879-80) where it is a very important staple; but in Julpigoree the out-turn was somewhat below the average.

THE *Morning Advertiser* suggests that the real cause of the troubles of Ireland lies in the fact that the growth of tobacco is absolutely prohibited under heavy penalties. Before this prohibition Ireland ranked among the regions producing the finer qualities of the leaf.

THAT all cigars are not exclusively made of tobacco is a fact more or less known to all. But we were scarcely prepared to learn on the authority of an American paper, that the tricks of the trade are so openly practised that an inventor has had the audacity to take out a patent for flavouring cigars with a compound consisting of rum, alcohol, oil of apple, tonka bean, valerian root, and laudanum.

NOTICE TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah. *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

REPLIES TO CORRESPONDENTS.

TASAR SILKWORMS' EGGS.—If X.Y.Z. (whose letter appeared in our last issue) will ask Major Coussmaker, Poona, for some Tasar silkworm's eggs, between 15th June and 15th October, that gentleman will be happy to supply the same.

WEEDS ON COFFEE AND TEA ESTATES.

TO THE EDITOR.

SIR,—For the benefit of some, would a brother planter be good enough to give us his opinion regarding the advantages or disadvantages of allowing weeds to grow on coffee and tea estates. It is the opinion of some that weeds allowed to grow on an estate in reality do not take so much from the soil as they return to enrich it when cut down. As far as I have observed, the chief aim of planters here has been to keep gardens as free of weeds as possible. It is therefore a question if this constant weeding does not mean loss of vegetable soil, and destruction of a garden in course of years. Allowing that plants are heavily manured on some estates, I can hardly bring myself to believe this system can replace the damage done by so much of the upper soil being scraped, by, as I have said, constant weeding. But as it is, information I seek, I feel myself out of place giving an opinion, and I hope to benefit by hints on this subject from men of practical experience, which I trust may appear in the pages of your valuable journal.

Neilgherries. NOVICE.

NOTE.—The soil is not damaged by weeding, but the reverse ; it is improved by the frequent "scrapings" it gets in removing weeds. They should, if possible, not be allowed to seed, and should not be left on the surface, but hoed in, when they become green manure.—ED., *I. A.*

LOCAL INDUSTRIES : CEMENT.

TO THE EDITOR.

SIR,—The Calcutta *Fortnightly Review* of 10th February spoke of the advantage to be derived from developing the resources of the country. Amongst other articles, it mentioned the quantity of cement imported, although this country was able to produce the article equal in manufacture to that imported.

The State ought to do more than simply wish such industries success. Where it is in its power, the State should surely encourage such an enterprise, by using the cement manufactured locally for all public works.

I lately heard of an order from the mofussil on Calcutta for a large quantity of the cement manufactured in that city, provided the rate was reasonable ; but owing to the price being equivalent to that charged for the imported article, the order was cancelled, and the imported article obtained. This order was on behalf of the State.

FRIEND OF NDIA.

ABOUT PAPER FIBRES.

TO THE EDITOR.

SIR,—The remarks I made in my last letter "that as a rule paper-makers know but little about botany, and botanists, *per contra*, little about the requirements of paper-makers" may be considered a somewhat bold and broad assertion, and perhaps require some little qualification.

So far as India is concerned, it may be taken for granted that, very few English paper-makers having visited that country, tropical vegetation with its exuberant and prolific growth must be almost unknown to them, except so much perhaps as they may learn from botanical books ; some small sample parcels of a so-called new fibre occasionally are shewn to them by brokers or dealers, who as a rule know but little or nothing of the plant from which such fibre is produced, cannot tell them where it comes from (or will not), whether it can be supplied in continuous and reliable quantities, and other details essential for a consumer to know.

Now from the nature of his trade the paper-maker possesses or should possess what is phrenologically termed the "bump of caution." He is generally pretty well able to judge by inspection whether the *fibre* shown him will or will not make a fair quality of paper, but before he will purchase, or indeed make an offer, he desires to experiment; and experiments (if carried out practically) involve much cost and trouble. Naturally, therefore, he wants to know the price not merely for a few cwts or tons, but whether he can (should the price asked induce him to test it) fairly count on a reliable and continuous supply; and unless such an assurance can be given, he declines troubling himself further.

With regard to the botanist, *he* seems to consider "all's fish that comes to the net", judging from the list of fibres and fibrous plants enumerated in Mr. Liotard's memorandum,—some of them utterly unsuited for English paper-making requirements, either on the score of quality or cost; many on the other hand suitable, provided they are available in quantities and at a reasonable cost. Unfortunately however, with one or two exceptions, no attempt in Mr. Liotard's publication has been made to indicate the cost at which these fibres can be procured in India itself, or at any port of shipment, nor are any details given as to their treatment or preparation—I do not mean the chemical treatment to convert them into "stock," but the ordinary rough crude treatment to produce or reduce the real fibrous portion of the plants named to a commercially marketable condition.

One of the reporters in Mr. Liotard's memorandum rather, to my mind, begs the question, by "putting the cart before the horse" when, in referring to the "Agave", he remarks:—"Neither the ordinary cultivator nor the middleman can be expected to produce (the fibre) until a demand arises". In my simplicity I thought that demand for paper material was notorious; be that as it may, surely the writer of these remarks can hardly expect the paper-maker to offer to buy an article before it is produced, or before he knows its quality and cost, or whether he can be assured of supply.

Another writer in Mr. Liotard's memorandum remarks.—"In attempting to introduce a new material for paper, certain difficulties may be expected"; "no matter how well suited it may be for the purpose, prejudice will not be wanting"; "there will also be difficulty in inducing any one to be the first to bring it in, and still more in getting any one to be the first to use it."

These truisms I fully endorse from experience; there are *always* difficulties in introducing *anything new*, whether for paper or anything else. Prejudice, however, on the part of the paper-maker may be defined by a strong disinclination to commit himself until or before he is assured the fibre will suit him. He has two vital points to consider:—first, whether it will pay him to use it—that is, whether it will favorably compare with the existing material which he can readily procure—and then, whether it will make a suitable quality of paper. It may be well to direct attention to the fact that not only will every different fibre vary in the cost of treatment, both chemical as well as mechanical, but will make a difference in the quality of the paper produced. And it must be borne in mind that the paper-maker has to compete in the market, and suit his customer, the printer, or other consumer, as regards quality—no easy task in these days of keen competition.

The technical details in the manufacture of paper are somewhat—indeed, I may say very—complicated, especially in the choice and treatment of raw material. It is said that to make a good bowl of punch, the essentials are "some of sour, some of sweet, some of strong, and some of weak." So it is with paper-making: it being difficult to name any one raw material combining all these qualifications, the skill of the paper-maker and the quality of the paper produced mainly depend on a judicious mixture or blending of the raw staple.

My endeavour has been, and is, to point out the practical issues to which attention should be directed in the choice and attempted introduction of any new fibre or fibrous product proposed, so as to narrow the chances of failure to intending experimenters who might otherwise be misled by the very voluminous list of fibrous plants enumerated in Mr. Liotard's publication.

Broadly speaking, I am induced to believe that commercial success will most readily be attained by confining attention to plants of rapid growth, *viz*., such as are produced annually from seed, or perennially, so to speak, from cuttings. Trees, that is forest trees, are too slowly produced to admit of their bark or bast being reliably and regularly procured in large quantities, more especially seeing the restrictions introduced of late in Indian Forest Conservancy. Although therefore, many of these barks which have come under my notice furnish good paper material, it appears to me the collection would be somewhat precarious and costly.

If some practical botanist or forester would give a list in your columns of some of the quick-growing trees, those especially of a shrubby habit, which might be grown as coppice, others which pollarded would furnish annual shoots, or which might be cultivated as the Japanese and Chinese do the *Broussonetia papyrifera* and, I believe, the Nepaulese the *Daphne* tribe—he would do good service both to India and the English paper-maker.

I need not recapitulate the long list of bark or bast-producing trees enumerated in Mr. Liotard's work, or those mentioned in Dr. Brandis's "Indian Forest Flora," and Dr. Royles' "Fibrous Plants of India," Dr. Balfour's works, and others—but I doubt not many might be so cultivated with profitable results.

My great predilection is for the bamboo (which however is not a bark, the whole of the plant stem, or tree, having proved available). It will make a very superior quality of paper, and is moreover most simply and economically treated and converted into "stock." Then there is the fact that a large annual crop is available by season cuttings, that it requires little or no cultivation, no attention, only judicious cropping; is of perennial growth, the present stool lasting many years; exists in enormous abundance in native forest or jungle, and so on. Under such favorable conditions the "stock" from bamboo can be produced and laid down in the English market cheaper, and certainly more abundantly, than that from *any other* raw fibrous plant which as yet has come under my notice.

One and only one objection to the introduction of bamboo exists—that being, that from its bulk and lightness, it cannot be exported from India as a purely raw product so as *to pay*. It must be converted into "stock" where grown, or near thereto. But as I believe that this objection applies more or less to *every other* raw fibrous product—one and all of which must for the same reason undergo some preliminary treatment—and the fact having been proved that bamboo is a *first* class material, I am satisfied its introduction is merely a question of time.

THOMAS ROUTLEDGE.

Claxheugh, January 1881.

HOT ICE AND ARTIFICIAL INDIGO.

TO THE EDITOR.

SIR,—*Heat* and *cold*, we are taught, are merely relative terms, and that *heat* is simply the absence of a certain degree of *cold*, facts which give great solace and contentment if remembered during the hot weather, when tormented with prickly-heat. But what of *hot ice*? An old Indian to whom I mentioned the fact of hot ice having been produced, turned pale, and replied "don't talk——rubbish to me!" The fact, however, remains that Dr. Carnelly in England has actually heated ice, until it indicated by a thermometer a temperature of 356° Fah. or 144° above the boiling point of water?

The apparatus employed by Dr. Carnelly to produce this phenomenon was recently exhibited at a meeting of the Chemical Society of London, and I take the following description from the proceedings of the Society. "The apparatus consisted of a wide glass tube ¾ inch in diameter, and about 5 to 6 feet high. This is placed in a vertical position, and is connected at its upper end with a strong glass flask placed horizontally and surrounded with a freezing mixture. The apparatus having been inverted and filled with mercury, the lower end of the tube is closed with the thumb and placed under the surface of a layer of mercury about 10 inches deep. On withdrawing the thumb the mercury sinks in the tube to the barometric height, and a large Torricellian vacuum is obtained, which is surrounded as far as the flask is concerned, with a freezing mixture. A small quantity of boiling water is now introduced, which rises to the top of the mercurial column and surrounds the bulb of a thermometer suspended inside the tube. The water is frozen, and the depth of the layer of mercury in which the tube stands is reduced to about 3 inches; in consequence the mercury in the tube sinks and leaves a detached column of ice with the thermometer bulb in its centre. This column acts as a cock, shutting off the large vacuous space above from the small vacuum below. By carefully heating the tube the ice is melted round the circumference of the plug, and a fine angular opening is made between the ice and the inside of the glass tube. This restores the communication between the upper and lower portion of the vacuum. As soon as this is effected, any aqueous vapour which is formed is at once condensed by the freezing mixture, and the vacuum is kept intact. Under these circumstances the author has made ice so hot that the thermometer in the centre of the cylinder stood at 180° before the ice melted."

From hot ice to artificial indigo is but a step; and the accompanying remarks by a Mr. E. B. Broomhall, in the *Home and Colonial Mail*, ought to cheer the spirits of indigo planters, especially after the rumours that the indigo plant is rapidly being superseded by the produce of the chemist's laboratory. It is true that recently a German chemist has patented a method for the production of artificial indigo, in which he makes nine claims; the first four of which apply to the artificial formation of indigo, blue and allied colouring matter, the remainder to the production of materials capable of being used in the preparation of the

same. It would be impossible to go into a full chemical history of the process here; suffice it to say that it is a long and tedious one, and that each successive substance obtained is very small in quantity, so that when indigo is reached the quantity obtained is almost infinitesimal as compared with the original base. The formula is a new one, but the manufacture of artificial indigo is old.

"The supersession of madder by the success of artificial alizarin must not for a moment be taken as a proof of the probable success of Professor Baeyer's discovery. Fine commercial indigo contains 85 per cent, and perhaps even more of pure indigo, while the amount of alizarin—the active colouring principle—in madder does not exceed one per cent. In addition, the processes by which cloth was dyed with madder were costly and difficult, whereas the use of indigo meets with no such drawback, dyeing with indigo being perhaps, of all dyeing operations the most simple."

"From the above it will be seen that whereas in the case of madder there was scope for the artificial production of alizarin, it is very vastly different with indigo. At present it costs twice as much two produce this dye stuff artificially as compared with to-day's market quotations, and there is no doubt that, given average harvests in India, the planters would make a profit at half the present price, and were more scientific attention given to the manufacture of the plant into indigo, I have no hesitation in saying that the article could be produced at still even a greater reduction. Although it would be presumption on my part to say that the artificial production of indigo will never be a success, still it is now only in the laboratory stage, and it will probably be long before it can compete successfully with the natural dye, if ever."

"The many blues, blacks, &c., derived from aniline cannot be used for the fundamental work of indigo; it may be generally known that all our best blacks, blues, greens, and many other coloured cloths, have first to be dyed with indigo and then finished with the colour desired. The indigo gives a depth of tone and weather-resisting property to the material treated, which would not otherwise possess. Instead of being rapidly 'superseded,' the production and consumption of indigo yearly increases, and the new colours affect it only in a subsidiary degree, inasmuch as they give the public a greater range of choice of shades, whereas had it not been for the coal-tar dyes they would have been confined to a selection of the good old fashioned tints, which would bear rain, fog or sunlight, without any deterioration so unlike the many beautiful colours now in vogue, which do not look to particular advantage after a slight shower, leaving alone the fact that many of their colours are actually poisonous to the wearer."

SHADE FOR CACAO.

I.

(To the Editor of the Ceylon Observer.)

DEAR SIR,—Any information regarding the cultivation of cacao is of interest at the present time, and this I trust may excuse me troubling you with a few notes on my experience of the culture of *Theobroma*, (food for the gods) in the plantations of the West Indies. Your late supplement was most interesting, containing the report of Mr. Prestoe, the Government Botanist of Trinidad, on his valuable services, in providing for Ceylon seeds and plants of the best strains of cacao, and its shade plant, *Erythrina umbrosa* or the *Bois Immortelle* of the French. This tree no doubt forms a most excellent shade, but was not in such general use in Grenada (where my experience was principally gained) as in Trinidad. The *Bois Immortelle* was more used in the former island, as a boundary tree, between estates, and its specific name, I take it, arose from its almost indestructible nature and tenacity of life, and not from the facility of its propagation by the smallest cuttings, as mentioned by Mr. Prestoe. It was looked upon by us as a sort of everlasting tree, and hence invariably used as a land mark. We have an excellent shade *Immortelle* in Ceylon, a close ally to the W. I. *Erythrina*, and of the same family; it is the *Butea frondosa*, the *Eramuda* of the Singhalese, a tree of middle size, with large trifoliate fleshy deciduous leaves, and bright red racimes of pea-shaped flowers. It is one of the most common fence sticks, used by the natives, and strange to say, it and its sister tree (*Butea superba*) are here used as *boundary* trees, in the same manner as their congeners *Erythrina* are in the West.

Now as regards *shade* for cacao, or say tea or coffee, I believe many erroneous ideas have existed. I can at least vouch for it that my own theories—before experience was gained—were of a very crude nature. It is frequently overlooked that the *roots* of plants are the members most in want of shade, and that to accomplish this is the principal object for temporary shade over the young plants. Leave out of view precautionary measures for protection against wind, and I say that in very few cases will any permanent shade be required after the plants have formed mutual shade for one another, or as the phrase is *have bowered*. In the cultivation of cacao in Grenada, this fact was recognised in all sheltered situations, and the plantain tree, as a rule, formed the only temporary shade. As to the importance of shading the roots of young plants, I would be inclined to go further, and question how far it is judicious to weed so scrupulously clean between the rows as is generally the custom. Many will have observed for instance in the case of young tea plantations, how luxuriant and healthy the plants often look when half smothered with *Ageratum*, as compared with their neighbours which have been thoroughly weeded, and whose roots have been more or less exposed to the scorching sun. Where it practicable, I believe the best of all shade would be a good sound litter of ferns, grass, or brushwood, but of course the danger of fire prohibits such a system. To return to our Ceylon *Immortelle* (*Butea frondosa*) I think it would make an excellent shade tree, quite equal to *Erythrina*. One great advantage the *Immortelles* have over many other trees, is that they are poor feeders, with a spongy good-for-nothing wood which requires little sustenance from the soil. Fruit trees in Grenada were frequently planted along with cacao, such as alligator pear, nutmeg, pimento, breadfruit cloves, and all the orange tribe. These were, however, intended more as a shelter from the wind, than as shade trees,—a free exposure to the sun not being looked on as prejudicial to cacao, where an average rainfall could be relied on.

A query appeared sometime ago in the papers, as to whether it would be advisable to plant cacao trees on their permanent site. I never knew any other plan adopted in the West Indies; planting out from bamboos, pots, or baskets being almost entirely unknown, I believe planting out seeds at once would be very advantageous in Ceylon, provided a proper system of shade was adopted. Mr. Fraser seems to have had great success with his Trinidad seeds of *Erythrina*, and it would be interesting were he to try, by way of contrast, our Ceylon *Immortelles*. I would also strongly recommend the plantain as a shade tree; it answers admirably in throwing a temporary shade, and once it dies down, a large mass of fleshy decayed vegetable matter is left at its roots, which forms valuable sustenance for the cacao. The plan adopted was to dig oval or oblong holes, placing a plantain shoot at one end, while at the other a couple of seeds of cacao were dropped. The fruit yielded by the plantain was supposed to pay all expenses until a return was got from the cacao. Our native *Immortelle* is extremely easily propagated, and a good sized branch stuck in the ground, will become a tree, in a marvellously short space of time.

A. WHYTE.

Kandy, 20th Dec. 1880.

II.

DEAR SIR,—I write to prevent, if possible, trouble to planters in trying to secure the plants named by Mr. A. Whyte in his letter in your Saturday's issue, as shade trees for cacao in Ceylon, and to give some facts respecting the plants named by him, which I trust may be found useful:—

1. *Erythrina umbrosa* is a native of South America between La Guayra and Caraccas, where it is called *Bucare*, and where it is planted in rows to shade the plantations of Theobroma cacao. It is also used in Trinidad for the same purpose.—*Don.* Its specific name indicates that it is a shady tree and may be useful as such. This tree may be called *Bois Immortelle*, but the tree bearing this name in Barbados, is the *Erythrina corallodendron.*

2. *Butea frondosa*, the Gaskela of the Singhalese, is a remarkable historical tree, from the fact that the battle field of Plassey, near Calcutta was so called from Palasa, the Bengali, or Palas, the Sanscrit name of the tree, which grew in this plain. The tree is so rare however, in Ceylon, that I think it is most likely Mr. Whyte has never seen one, unless he has done so in the Royal Gardens at Peradeniya.

The paragraph in question indicates that he has mixed up our own two *Erythrinas* with the *Butea*, the *Erabadu*, and *Yak-Erabadu* of the Singhalese, the *E. Indica*, and the E. *ovalifolia*, which grow readily from cuttings, and are used as described by Mr. Whyte, but these trees are remarkable for shedding all their leaves, and for flowering just before the development of their leaves. Why they should be called *Immortelles* I do not know, as a tree which is often and for considerable periods of time devoid of leaves and flowers, can scarcely be called *everlasting*. The *E. umbrosa* may prove a valuable shade tree, but I can scarcely recommend our two native *Erythrinas* for this purpose. Moon in his catalogue, 1824, gave the *Butea superba*, as a native of Ceylon. This plant is said to differ from *B. frondosa* mainly by its scandent habit. It is not given in Mr. Morris's list even as growing in the Royal Gardens, and I may assure Mr. Whyte that Dr. Trimen will be very grateful for any specimens of this supposed common plant which he can send him. It is not given by Dr. Thwaites, nor is it given in the Flora of British India as a Ceylon plant.

I may conclude this note by quoting a Singhalese proverb or fable like that of the fox and the grapes:—"As the jackal praised the beauty of its flowers (*Butea frondosa*) to induce them to fall down." Flattering when a favour is wanted.

W. F.

CINCHONA NURSERIES: PRACTICAL HINTS

(To the Editor of the Ceylon Observer.)

DEAR SIR,—In recent issues of your paper, a number of inquiries appear, in reference to the rearing of cinchona plants.

When one considers the millions of seedlings reared and the small, very small, proportion of plants returned; perhaps a few practical hints may not be altogether unacceptable to the many who are now interested in cinchona.

Planters have often expressed their surprise to me at the enormous percentage of deaths which occur in cinchona supplied among coffee, or put out into clearings, and conclude therefrom that cinchona is delicate, and a successful clearing depends upon most favourable planting weather.

That plants die by thousands, I admit, but that cinchona is delicate, I deny. The reason of most of the deaths is, in my opinion, attributable to badly reared plants in nurseries. I have seen nurseries where the plants were estimated by millions. The seed had been sown and allowed to grow as thick as possible the shade gradually removed, and the tops only hardened, but where were the roots of these so-called plants? In a square foot where the plants could be counted by hundreds how was it possible for roots to form, or the stem near the ground to harden?

There is no wonder that such plants as these die but a very great wonder if they live. My cinchona nursery has returned seventy-five per cent of very fine plants with branches of roots from seedlings pricked out; and I feel assured if the same process is adopted, equal success will attend other efforts.

The first thing in beginning a cinchona nursery is choice of ground. Great care should be taken that the soil, is not of a fatty or clayey nature. The freer the soil the better. The nurseries I have seen on Patna land where the earth was black and fatty, have been *complete failure.*

It is not necessary to dig the ground up the same as a coffee nursery. Beds should be rounded at the top a little, to admit of nice drainage; sticks and all rubbish removed to the depth of five or six inches, then good free jungle mould brought thoroughly cleaned and *fired* before putting on the bed as a final dressing.

The firing process is recommended by Mr. McIvor, but is not usually adopted, and does not accomplish all he says it will. All insect life, eggs, worms, and caterpillars of all kinds are destroyed; but seeds of some varieties of weeds retain their vital energies, although the earth is heated to scalding point. I need not enlarge upon the necessity of having all vermin removed. The advantages must be patent to any one.

The best way to fire the earth is to get an ordinary sheet of corrugated iron, which is used for roofing, raise it far enough from the ground to admit of a good fire being made under it, then put on a half-dozen baskets full of the jungle earth above described, stir it well up till it is scalding hot, and empty on a heap, and keep for a day, to allow of it gradually cooling, when it may be used. This earth need not be put on deeper than three inches.

The next thing is to erect roofs over the beds. They must be put up in such a manner as to admit all the light of heaven, and at the same time exclude the rays of the sun. If the roofs are of such a form as to exclude light, and allow a semi-darkness to prevail in the centres, the seedlings will scarcely sprout at all, and what may come up will be spindly, delicate, and so very sensitive to the rays of the sun, that when pricked out under ferns they will be scorched off by scores.

The advantages therefore of having all the light possible on the seed beds are obvious. The seeds sprout ten times better, and as they grow, gradually harden, so that when pricked out under ferns, they are able to withstand the sun's rays. I have seen a dozen different kinds of seed beds roofs, and the one I have chosen as the best, gives all the advantages to the seedlings, above described, with none of the evils.

First of all, the seed beds should be made parallel with the course of the sun, that is, one *end* of the bed should face the east, and the other should face the west, and should not be more than four feet wide. The roofs should be erected over the beds facing the north. The top of the roof should not be less than five feet high, and the back about eighteen inches from the ground. The roofs should be erected behind each other. Care should be taken not to build the roofs facing the south, for then the sun would play upon the seed when sprouting, and kill it.—Yours,

CINCHONA.

Calcutta, February 1, 1881.

SORGHO CULTIVATION.

(To the Editor of the Madras Mail.)

SIR,—In reply to "L.," I regret that I have no personal knowledge of Mr. Stewart's new process of manufacturing sugar from sorgho; the methods however are, it is stated, described in Commercial Blue-book No. 1 of 1879, called "Report by Mr. Drummond on sugar production in the United States." A book-seller will procure this if it be ordered. The ordinary sorgho if procured fresh from the Government Farm at Madras, is probably the best obtainable in this presidency; the Otaheitan variety of imphee is as good as sorgho, but is probably not procurable. "L. will find directions for growing "sorgho" in the *Mysore Gazette* of the 20th July 1872, which also mentions the uses of the plant Mr. Robertson of the Madras Farm, considered the result of the Bangalore experiments to be very encouraging, the plant seeming suited to the Mysore climate. In considering the results of previous experience in sugar-making, which have not been altogether satisfactory, it should be especially borne in mind that the experience was all long prior to 1879, and that Mr. Stewart's discovery of a new process, whereby the manufacture of sorgho sugar is said to be made certain and simple, will, if correct, render previous negative experience of no value as a guide for future experiments. There is an account of sorgho taken from Powell's "Punjab Products" in Drury's "Useful Plants of India." It is planted in drills 3 or 4 feet apart; the stocks grow about 2 feet apart. It makes a fourth to a fifth of its bulk in good syrup (query, "juice'). On the first trial 70 average canes, passed once through the rollers, gave 38 gallons 1 quart of juice, and a second time 2 gallons of juice, the 40 gallons so obtained yielding 8 gallons of syrup. An acre of land planted in rows 4 feet apart, and with stocks 2 feet apart should give about 5,400 canes, the yield of syrup would be above 600 gallons. This, at 6lb. of sugar per gallon, would be 4,800lbs. over 2 tons per acre.

N.

The Indian Agriculturist.

CALCUTTA, MARCH 1, 1881.

MR. SCHROTTKY'S REMEDY FOR COFFEE LEAF DISEASE.

THE alleged discovery by Mr. Schrottky of a remedy for the leaf-disease which has produced such baneful results in Ceylon, seems to be absorbing a deal of attention in that island. The Colombo journals are full of it; meetings are held, and discussions inaugurated, all tending to a consideration of this great discovery. So far as we can learn from these journals, the consensus of opinion is with Mr. Schrottky; but a careful examination of the whole literature of the subject fails to convert us, or to change the opinions we expressed on a previous occasion (Vol. IV. page 399.) We are willing to accord Mr. Schrottky credit for having discovered a palliation for the disease, as there does not seem any reasonable doubt that his remedy has a beneficial effect. This effect, however, is not permanent, and to quote the discoverer's own words, the effects do not last over a few days:—"And now as to the "time the beneficial effect of either treatment lasts. Speaking "chiefly of the vaporisation, its effect may absolutely be depended "upon for ten days to a fortnight." It is not then a cure at all. A specific for any disease, which only wards it off for a few days, is not likely to achieve much success. We have watched these experiments with much interest, because, having taken up a certain position at the close of 1879, we should have been compelled to abandon it, had these experiments proved entirely successful. That they have done so to a certain extent, is no doubt very much to Mr. Schrottky's credit, and we trust he will continue his investigation, until he masters the difficulty thoroughly. He belongs to a race who develope strong perseverance in the pursuit of an object, and we are sure Mr. Schrottky will not be found wanting as a patient investigator. The position we have already taken up is, that this disease is not a leaf-disease at all, and consequently no topical treatment will meet the difficulty. It is in our opinion a radical disease, and as such, requires constitutional treatment for its cure. Had Mr. Schrottky's remedy been a complete one, we should naturally have been compelled to abandon our opinion; but the whole gist of Mr. Schrottky's lecture would seem to indicate that he is at one with us, as he nowhere speaks of a permanent cure having been effected. The most he promises the Ceylon planters is that the evil effects of the disease may be minimised,—perhaps entirely annihilated—by three applications of his remedy, at two seasons of the year. As one course of treatment is estimated to cost Rs. 3 to Rs. 12 per acre, the remedy

will entail an annual outlay of, say, Rs. 21 per acre. This is not out of the way to secure success, and we are sure that no planter would grudge the amount. We do not profess to be deeply versed in chemistry, but we fear Mr. Schrottky is incorrectly reported when he is made to say:—"The chief point in evaporation "was to produce vapour of carbonic acid, which continued in "the atmospheric air for a period of, say, six to eight days." This seems to us to require explanation. It is surely not intended to convey the opinion that if vapour is thrown into a plant, it will hang about it, and exert its curative influence for a week.

We do not so much object to the cure as to its mode of application. If it is desired to have the "medicine" absorbed by the plant, why innoculate the stem, or vaporise the bush? Nature has provided a medium for purposes of absorption, and it would surely be the most natural process to place the remedy within reach of that ordained medium, the roots. Even were this done, we very much fear that but small success would follow. We must cease to treat it as a leaf-disease, and give the plant instead, constitutional treatment. It is no answer to this to say that the disease only appears on the leaves. Skin eruptions of the human body only appear on the skin, but no medical man would treat them as if they were merely skin diseases. He may apply topical remedial means to relieve the suffering, but if he desires to get rid of the complaint thoroughly, he seeks the root of the disease, and most probably finds it in a diseased or debilitated condition of the blood. Such, we apprehend, is the case with this disease under notice. For years we have grown coffee on the same fields, never varying or changing anything, but year after year expecting a crop; and when at length we found Nature rebelling, we took to pruning, to compel the plants to make an effort. This they did, but at the expense of their general health. If we grow the same grain year after year on the same spot, we find a deterioration takes place; but as the coffee plant is a perennial, we cannot, without heavy expense, change the locality of our soil. Under these circumstances we ought to come to the rescue by giving the plant generous treatment. This we only do to a very limited extent; and it is absurd to expect the plant to retain its healthy habit under such treatment. The same treatment, only in a more exaggerated form, is given to the tea plant, and consequently it too has rebelled at even an earlier stage of the industry. The tea plant is subjected to treatment which is entirely opposed to its habits, and therefore it is not to be expected that its normal condition should be one of health. It is prevented from maturing its seed, in order to carry out the grand reason for its existence. The plant is every year cut down and compelled to grow as a bush, whereas it has the habit of a tree—but the China variety, having the habit of a bush, is not subject to these diseases as a rule—and week after week, as the plants put forth their recuperative powers, the young and vigorous shoots with their tender leaves are systematically stripped, to meet the requirements of the planter. The two diseases, of the coffee and tea plant respectively, may be the result of different fungoid growths, but the primary and predisposing cause in either case is we believe the same, *viz.*, poverty. In reply to this it has been stated that the young seedlings in Fiji showed symptoms of the disease, although they were growing in absolutely virgin soil. This, however, is only a further proof that the disease is constitutional; for it must be remembered that the seedlings referred to were raised from seed from Ceylon or Southern India, and consequently were diseased.

Although we have never dogmatised on the subject of leaf disease, but have put forward our views subject to correction, we have never yet met an argument which has led us to change our opinion. While others have advanced their several hypotheses, we have advanced ours, and we have not failed to give reasons for our opinions. Let more attention be given to our cultivation, that we may to some extent compensate the plant for the abnormal treatment to which we subject it. Let us remember that we are deliberately thwarting the natural instincts of the plants by our modes of treatment,—modes albeit rendered imperative by the demands of the industry. The tea and coffee industries are of course carried on with a view to profit, and if with this aim in view we have to thwart the natural growth of the plants, we should not fail to help the recuperative powers of those plants which are so remunerative to us. While we hold the opinion that the plant wants, and deserves, more generous treatment, it does not follow that the soil is exhausted. That this is not so, is proved by the fact that on any given patch of land where this blight does not appear for a time, a fairly remunerative crop is obtained. Were the land generally exhausted, coffee would cease to give returns at all commensurate with the outlay or capital invested, and the industry would speedily be abandoned.

There is a singularly close analogy between plant and animal life; and as we find in the latter, that a certain variety of food is essential to a healthy existence, so we find with the former, that if one element in plant-food be absent from the soil, the plant may grow; but will never fully achieve the objects of its existence—in short, will never become a really healthy plant. Now the coffee plant has a very large proportion of lime in its composition, and as it is cultivated year by year, necessarily on the same soil, it is not unreasonable to suppose that, in process of time, the true proportion of lime required for the due nourishment of the plant becomes deficient. The plant thus gradually acquires a debilitated habit, and becomes a prey to diseases of various kinds. Our theory is, that if the plant were vigorous and healthy, it would not only be able to throw off these parasitical attacks, but would be able to prevent them altogether. A corroboration of this theory occurs quite accidentally, and is thus described in a Colombo contemporary:—

> We have learned to-day a rather important practical corroboration of the value of carbolic (carbonic?) acid as a remedy for leaf-disease. A few years ago, Mr. Wm. Smith of Matakelle, Dimbula, obtained from Colombo a certain quantity of gas lime, for some purpose which afterwards passed out of view, and not knowing what to do with the strong-smelling stuff, he had it thrown over a certain part of his coffee. He very soon noticed the beneficial effects, and for some time this was his show-field of coffee.

This application of gas lime was given when an attack of leaf-disease had just commenced, and the planter found that a second application was not so effective, possibly because the conditions of the plant had changed, just as a medicine applied to a healthy subject does not take effect so markedly as when the experiment is made on an unhealthy one. We feel convinced however, that what is wanted is a scientific investigation, not as to leaf-disease, but as to the general conditions under which planting is carried on, with a special view to ascertaining the nature and quantity of plant-food absorbed from the soil every year. This ascertained, the application of the proper remedy—to the soil, to the leaf, or the stem—will follow as a matter of course. "The knowledge of a disease is half the cure", and this has as much force when applied to plant as when to animal life.

THE TEA COMMISSION.

I.

THE report of the Commission on Act VII. (B.C.) has now, we imagine, reached and been thoroughly discussed on the remotest tea garden. That much diversity of opinion on the result of the Commission's labors will arise we may expect, but, as the amended Act will no doubt receive the assent of the Government, and be passed into law, we recommend the planting community to acquiesce in its provisions. It is not our intention to review the preamble in its entirety, but merely to comment on such sections as appear to us the most important. Much, indeed, of the old law the Commission propose altogether to expunge and the modifications of other sections seem to us to be just and demanded by the altered condition of the tea industry and those engaged in it, from the time when the original Act was promulgated. Many planters are of opinion that an entirely new Act would have been better, as it would have been more clearly and easily understood by those unaccustomed to the verbosity of all legal phraseology; but so long as lawyers endure, we presume that such verbosity must continue. The prospects of tea planting are such that the draft Bill, to have any ameliorating effect on the industry, must at once become law; but in sections 5 and 6 the Commission indicate a wish for further discussion and the expression of opinions from those interested in the matter. This, if allowed, must of necessity entail great delay, and we think Government might, until such opinions have been sifted and digested, suspend most of the vexatious restrictions on immigration which the new Bill proposes to abolish. At the same time we would urge on planters and their agents the great importance of rapidly recording their opinions; the Commission ought to have been appointed

eighteen months ago; but though we pointed this out at the time, it is useless to dwell on it now.

Section 10, in which the contract time is raised from three to five years, will meet, we presume, with pretty general approval, for the argument in favor of such extension is just and equitable alike to both parties; but we should have liked all reference to the bonus omitted. In the latter part of this section a clause occurs which is hardly fair to the coolie, as it is proposed that he should work on any estate belonging to the firm for which he is engaged; thus, a man may elect to work on an estate that he may have worked on before, and yet find on arrival that he is destined for an out-garden opened since he went to his country, and, perhaps, situated in an undesirable locality; this, we submit, is a matter that needs revision. Section 16, dealing with the registering officer, is at least a step in the right direction, and as, during the immigration season, it is seldom that the magistrate is in the station, full powers ought to be conferred on the Civil Surgeon, who is (or should be) a fixture, and is certainly the best qualified person to inspect, register, and pass immigrants. Sections 17 to 41, embodying the Commission's views on sirdari recruiting, appear reasonable; for anything tending to prevent unnecessary delay in forwarding newly-recruited coolies to their destination is to be recommended, and nothing is more apt to encourage dissatisfaction and desertion than the keeping of a body of men dancing attendance at a cutcherry for an indefinite time, exposed to the exactions of the amlah and danger arising from crimps. If it is deemed necessary to take coolies before a mofussil officer for registration or inspection, we are of opinion that each station and sub-division within the recruiting district, and on the line of route thence to the tea district should be constituted a registration station, as it might be frequently advisable to avoid certain stations either on account of their remoteness from the line of march, or the presence of epidemic disease. The entertainment of numerous local agents within the recruiting districts themselves will entail, at the outset of the proposed scheme for free immigration, considerable expense, but as experience proves how unreliable garden sirdars are when left to their own unsupervised devices, this cost must be faced or the present frequent embezzlement and frittering away of funds would be largely increased. If natives are employed as local agents, it would be better that they should be either the headmen of villages, or persons of standing and respectability, and their remuneration, whatever it may be, should be paid on the arrival of the batch on the garden, not on the gang leaving the village. The local agents, moreover, must be provided with all necessary authority to prosecute defaulting sirdars, many of whom have, it is well known, established themselves as money lenders and *moodees* with the moneys entrusted to them for recruiting purposes. It will, we fear, be a difficult task to bring home to a recruiting sirdar the offence of paying into contractors' or crimps' hands, and the hopes of counteracting such practices lie in the probability that free immigration will abolish the contractor altogether. The suggestion as to the way bill is also a good one, inasmuch as it will provide reliable records of the sirdari recruiting system. The detention of diseased or sick coolies by any magistrate is a necessity, but where are they to be lodged, and what is ultimately to become of them? The concluding paragraph in the section under notice runs thus:—

"If any employer desires to have his laborer brought through Calcutta and inspected by his agents there, this can be done under section 43 even although the contract may have already been executed at another registering station."

Now we think it most undesirable that coolies should be brought into the city, but would suggest that a clerk from the agency house should go up to the selected depôt and inspect the coolies there. It has been pointed out time after time how unsuitable Calcutta is for junglies and up-country men, while the risk of acquiring epidemic or contagious disease and disseminating it among the halting stations on the upward route, would be much greater than if the emigrants were forwarded direct on their journey from the mofussil depôt. In the interests of the city itself, the municipal authorities ought to protest against the influx of such considerable gangs of men as the free immigration scheme may bring down country. The section dealing with the establishment of depôts by contractors, and the granting of and suspension of licenses, call for little remark; but in all cases where an officer cancels a license the reason for such proceeding ought, we think, to be endorsed on the back of the documents, as it is now usual merely to inform the contractor or the manager of the gardens that such license has been cancelled, and request that the man may not be sent up again, the details of the alleged misconduct which necessitates the step not being furnished. Whether the restriction of the medical examination to ascertaining simply that intending emigrants are fit to travel and are free from contagious disease is wise, may be doubted, as it would leave room for considerable abuse on the part of both contractors and sirdars, who in addition to the useless dependents could include in their batches many men and women utterly unfit for garden work, but whom under the proposed restriction, the medical inspecting officer would be powerless to prevent from proceeding. Without meaning to insinuate aught against the inspecting officer, we may remark that the payments of fees on all, whether rejected or not, and the hint conveyed in the words—

"the work imposed on a registering officer is greater in the case of a rejected, than of an accepted laborer,"

appear to offer a premium on the passing of the halt, the blind, and the maimed.

The proposals relating to transport appear to have been well considered, and doubtless the scale of diet and medical comforts, together with the rules for accommodation, have been drawn out more in accordance with the dictates of common sense than appears to have been formerly the case. Sections 78 and 79, altering the method of payment of carrying licenses, is, we think, equitable, as is also the suggestion that the measurement of vessels (regularly engaged in the transport service) every trip should be discontinued. We hope that the anticipation of the Commission of an accelerated steam service between Dhubri and Debrughur will be realised, Mr. Brown's extraordinary minute notwithstanding, which is certainly out of place attached to the report under notice. We trust the suggestion as to simplifying way bills, and consigning the useless form and passes to the waste-paper basket of the past will be adopted. The application of all surplus funds, accruing from fees, to the reduction of such subsequent expenses will no doubt be conceded, as Government cannot, we presume, wish to make a profit from such sources. The argument adduced in favor of the proposal that the Inspector of Laborers should give previous notice of his intended visit to the garden, will probably result in the adoption of such a line of conduct, although there may be some officials, to judge by what we have heard, who would oppose it. Sections 112 to 116 give, apparently, power to the Inspector to interfere with the task-work on the garden, but it is to be hoped that this officer's decision on such matters will not be final, for the memory will be fresh still, in the minds of old planters, of the mischief wrought by an Inspector who had to be summarily removed from his office, some fifteen years back, by the then Lieutenant-Governor, Sir William Grey. True, men of that stamp are not likely to be entrusted with power under the present *régime*, but any interference on the part of a Government official with the interior economy of garden work must manifestly be subversive of the manager's authority.

Those sections relating to the sick and incapable laborer call for no special remark, and the Government, in justice to both parties, cannot consent to give up all control in the matter. Managers in these days may be trusted to look after these people, whose families would probably form part of their labor force. Sections 121 to 127 deal with the important subject of the food supply, and no better plan than that recommended by the Commission,—of leaving this matter to be dealt with by the local Governments,—could be adopted, as planters for their own interests will presumably take care that a sufficient supply of suitable food is placed within their coolies' reach at reasonable rates. With reference to the subject of closing gardens against a particular class of laborers, that matter can, we think, be reasonably left to the discretion of the Deputy Commissioner acting in consultation with the local medical authorities; for it is a well-known fact that places where mortality among North-Westerns, as they are called, has been absolutely appalling,

sink to the *minimum* when this class of coolies is replaced by men from the Santhal Pergunnahs. The suggestions as to dealing with insubordination and disregard of sanitary regulations should meet all requirements; but the suppression of habitual drunkenness is a matter more difficult to deal with. The illicit distillation of liquor on a factory can to a great extent be controlled by the factory authorities; but its clandestine introduction from without, especially in the neighbourhood of the hills, where no abkari laws are in force, is almost impossible of detection. The canteen system has many advocates, and perhaps is the best that could be adopted; but there are many coolies who can be trusted to spend a quiet evening with half a dozen comrades over a bottle of liquor in their own huts, and to compel them to consume what they wish for at the bar, because one or two men, with purely animal tastes, prefer getting solitary drinks and creating a disturbance, would be most unjust. If only one or two, as is frequently the case, are such incurable drunkards as to endanger the peace of the factory, it would be better that they should be expelled and refused a discharge ticket. They must then either reform, or return to their country, becoming waifs and strays like their similarly affected brethren in other countries. Section 141 will somewhat flutter those managers who have heretofore stocked their factories at the expense of their neighbours; and although the infliction of the punishment of incarceration is seemingly left to the discretion of the local magistrate, we believe most of the Deputy Commissioners hold the opinion that nothing short of extreme measures will check the practice the section provides for. One month's imprisonment appears, on the face of it, but slight penalty for downright robbery, but it must be borne in mind that it carries with it a stigma entailing the loss of social position, and few but the most callous would care to return to their situations on release; and in the interests of all concerned in the tea industry, as well as for the good name of a body of Englishmen engaged in conducting an important enterprise, we trust the local authorities will not shrink from exercising to the full extent the powers confided to them, and thus put a stop to a practice that has grown into an intolerable evil of gigantic proportions. With the exception of the concluding paragraph, which we notice in a separate article, the remaining sections speak for themselves. On the whole the Commission appear to have given the greatest care and attention to the accomplishment of the task confided to them, and, however conflicting may be individual opinions, they deserve the best thanks of all interested in the tea industry.

II.

In their concluding remarks, the Commission on Act VII. do but endorse the views that have been so persistently urged in our columns for a long time past, though it must be patent to all concerned in the industry that the only solution of the tea problem hinges on the question of cheap and rapid means of transit between Calcutta and the tea districts. It is manifest, we think, that Indian tea,—despite the advantages claimed for it, of purity, strength, and flavour,—to prove remunerative must be laid down in London at a maximum cost of ninepence the pound; for, the fall in prices must we believe, be taken as the future market value, and unless measures to secure this end are rapidly set about, the almost universal collapse of the enterprise appears a foregone conclusion. We fully concur in the opinion of the Commission that the cheapening and accelerating of the transport service will be more effective than any scheme that can be proposed of a Government system of free immigration; and the re-peopling of the fertile land of Assam and Eastern India will follow as a natural sequence, these parts resuming their former position as the great granary not only of India, but of North Burmah and Western China. Sufficient evidence that they *were* so is afforded, not only by tradition, but by the remains of temples, towns, and fruit trees, indicating former village sites—those silent monuments of antiquity that shew both the ravages of ruthless invasion and the prolific capabilities of the country. With the present jungle wastes brought under cultivation for food grains, and a rapid means of distributing such throughout less favoured parts of India, the periodical famines we witness would be but matter of history and, as the truth of this assertion is self-evident, Government, whose credit is now so good, might undertake the laying down of the two lines of rail necessary to bring about this desirable consummation; for it seems hopeless to look to private enterprise to do this. If the recent loan so rapidly and liberally subscribed indicates the rate of interest that such sums as 14 millions can be had for, we would urge upon the Government to invite tenders for a loan solely for the construction of lines of railway from end to end of the Assam and Soormah Valley, connecting them if practicable with the Northern Bengal State line, or at any rate bringing them down to the nearest point of existing East communication with the metropolis. The network of lines indicated by the Commission would, we believe, from the knowledge we possess and information we have been able to glean concerning the districts they would traverse, render their commercial success a certainty, and such success would be greatly enhanced as they became linked with the Assam lines proper. It was beyond the province of the Commission, we know, in treating of communications, to indicate the different commodities of import and export, but in asking Government to construct a series of lines entailing an outlay of several millions sterling of borrowed capital, it will be necessary to furnish such reliable statistical information as would justify the authorities in entertaining the scheme. And herein lies considerable difficulty; for, the advocates of the lines have two steamer companies to contend with in the first instance, and the Eastern Bengal Railway Co. in the other. The latter line, however, will ere long become the property of the State, so that its interest will be identical with the lines proposed for, and in connection with, Assam. But the battle with those whose interests are vested in the two opposition steamer lines will, (owing to the large number of shareholders), doubtless be a tough one. Some opposition may also be expected, we fear, from district officers who regard railways from the Indian point of view rather than the European and American. An axiom has been laid down by some would-be authority or other, that unless a country has a population of 400 to the square mile, a line through it will not pay—quite oblivious of the fact, as the Commission points out, that almost every railway in Bengal must be a profitable investment for capital, the exception, we presume, being the Port Canning line. It is gratifying to learn, on the authority of the Commission, that the Government of Bengal is fully alive to the commercial and administrative importance of connecting the central districts of the presidency with those under the Chief Commissioner of Assam; and we presume neither Government is likely to be deterred from carrying out schemes for the benefit of the people and the countries entrusted to their charge, by the representations of those who are interested in retaining the *status quo* of tedious, exorbitant, and tardy means of communication. The manner in which the late Chief Commissioner has pushed forward the rail and tramway as far as Dhubri, is deserving of the warmest thanks of all interested in Assam, and it is to be trusted that his successors will prosecute the good work until the iron-horse daily traverses the whole distance from Dhubri to the Bhramakund. It is by this means, and this alone, that the vast mineral and agricultural wealth of the richest valley in the Indian Empire can be thrown open to the world, a revenue secured to Government from a province that is now a drag on the finances, and famine, if not rendered impossible, at least robbed of its horrors.

How the Commission came to permit Mr. Brown to append to the Report his extraordinary minute it is impossible to conceive—unless indeed upon the principle of giving a man rope enough, in which case it has succeeded most admirably. Surely this gentleman, while recording his protest against Government running a line to Assam, must have been fully aware that the company or companies whose champion he apparently constitutes himself have not a single steamer in their fleet that could compete either in speed or cheapness with the railway. Government no doubt would be quite willing to leave the development of the Assam provinces to private enterprise and energy even now, but it has waited sufficiently long to have had forced on it the conviction that these qualities are non-existent, in Bengal at any rate; and however much Mr. Brown and his compeer may deplore the fact, it must be self-evident to them that the days of steamers on the rivers of Assam are numbered. These com-

panies have had their day, and a profitable one it has been; but to endeavour to stem the tide of progress in these days by an attempt to create opposition to a Government that is developing trade, simply because the apathetic (so-called) commercial community will not do it for themselves, is mere puerile selfishness. Moreover, if we mistake not, Mr. Brown's firm, in addition to being interested in river steamers, is also agent to the largest Tea Company in Assam, and how that gentleman can reconcile his duty to the Assam Company with his cavilling at the projection of a railway through the Valley, by which that company would be vastly benefited, we leave for his own serious consideration. If he does not agree that "the proposed acceleration is so urgent as to demand Government interference," will he tell us in what way his own or any other steamer company purposes providing the requirements of the province with such. As for the liberal offers, we have had quite enough of such liberality, and the handsome dividends of the I.G.S.N. Co. show clearly enough that reductions both in freight and passage-money could be made. Not that we expect that Company will make the concession, until railway competition forces it do so or runs it off the rivers altogether. The history of river steam companies, as pourtrayed in this minute, is merely the history of stage coaches and postchaises of our grandfathers' days, and there are possibly some among your readers old enough to remember the opposition of the Parliamentary Committee even to George Stephenson's railway. But that a gentleman engaged in commercial pursuits in the capital of British India should remonstrate against Government undertaking a commercial enterprise, which those most interested in, either will not, or cannot, do for themselves—reflects but little credit on the enterprise of the commercial community of the chief city of the Empire. Had the river steam companies possessed a spark of energy, they would, by altering their vessels to light draught—*real* river steamers, of the American pattern—have postponed the projection of the proposed railways by some years; but their whole history shows that the very last thing they ever consulted was the public convenience. It is but recently on the Assam line that they have shewn any attempt at punctuality; as for the Cachar service, the utter want of system has become a byword, and this remissness is likely to lose them the greater part of the traffic this coming year. They certainly have no one to blame but themselves.

The concluding paragraph of this minute, alluding to the tendency of Government to engage in trade being alarmingly on the increase, is hardly applicable in the present instance, as for months the advertisement for swift steamers for the Dhubri and Debroghur service remained unanswered, and hence Government was compelled to place them on the line itself: and now to ask for the reversal of this "policy," solely in the interests of a section of the community who are interested in retarding the opening up of an important province (for the protest amounts to nothing else), is as likely to be endorsed by general public opinion, as would be a denunciation, by the ghost of Vasco de Gama, of the Suez Canal, the P. & O. Co., and the Overland route in general.

PSEUDO-GUTTA PERCHAS.

OR SUBSTANCES SUPPLEMENTARY TO GUTTA PERCHA.

FOREMOST amongst Pseudo-Guttas as we use the phrase, stands Balata Gum. It is obtained from the *Mimusops Balata* of Gœrtner (*Nat. Ord. Sapotaceæ*) and is synonymous with the *Sapota Mulleri* of Bleekrod, the *Achras Balata* of Aublet, &c. It is found in Demerara, Berbice, British and French Guiana, Antilles, Jamaica, and Surinam. It has many vernacular names, amongst which may be mentioned, Balata, Paardenoleesch (Dutch-horse-flesh), bullet tree, &c.

One of the first writers on this substance was Professor Bleekrod, who communicated some information as to the plant and its product to the Society of Arts, in 1857. He, too, described the plant and named it *Sapota Mulleri*. In 1860 Mr. Walker communicated samples &c., received from Dr. Van Holst, of Berbice, to the same society, and in 1864 Sir William Holmes also drew attention to the same subject. The tree is a large one with a trunk of about six feet in diameter, and furnishes a wood much liked for building purposes and of the colour of horse-flesh—hence the Dutch name. The bark is thick and rough, and the fruit is of the size of a coffee berry, sweet like a plum, and with a hard white kernel which yields a bitter oil. The leaves are glossy, oval, and acuminated. The milk is drunk by the natives, in cases of diarrhœa, and when diluted with water it is used as cow's milk. The trees grow in groups and in alluvial soil.

The "Balata" gum is of a character somewhat between caoutchouc and gutta percha, combining in some degree the elasticity of the one with the ductility of the other, freely softening and becoming plastic and easily moulded like gutta percha. What small parcels arrived in England met with a ready sale and were remarkably free from adulteration. But, unfortunately, through the difficulty of collection—the undertaking being so dangerous and unhealthy—the supply of this excellent article has fallen off. It is collected by making incisions in the bark about 7 feet from the ground, and a ring of clay placed round the tree to catch the milk as it exudes. The yield is said to be in profusion especially at the time of the full moon, and the operation can be repeated every two months in the rainy season. It takes six hours to bring about coalescence by simple atmospheric influence, but very quickly by boiling in water. A large tree is said to yield as much as 45lbs. of "dry gum." The tree in every way is well worthy of a trial by acclimating it.

In India there are several plants whose products may be classed as Pseudo-Guttas. First and foremost of these we have the Pauchontee or Indian gutta tree, the *Bassia elliptica* of Dalzell, the *Isonandra acuminata* of Lindley, but now known as *Dichopsis elliptica*. It is found in the Wynaad, Coorg, Anamally and Neilgherry Hills, Sholah Forest, Cochin, Sichar, and, according to General Cullen, "appears to be common in all the forest tracts at all within the influences of the south-west rains." This tree, which is now placed in the same genus as the true gutta percha, is a large one—from 80 to 100ft. high—and was first met with by Mr. Dalzell in North Canara, near the falls of Goirsuppah, in 1849. Since that date General Cullen and Dr. Cleghorn have used every exertion to bring the substance prominently forward, but without success. The gum is obtained by tapping, a pound and-a-half being obtained from one tree by five or six incisions, a large tree yielding as much as 20 to 40lbs of sap. Many experiments have been made with specimens of the raw milk, *i.e.*, milk simply dried by exposure to the atmosphere. The results of these experiments have shown that for telegraphic purposes it is wanting in some essential qualities, but it has been recommended as a sub-aqueous cement or glue. When dissolved in ordinary gutta percha solvents, it, after the evaporation of the solvent, remains some time soft and viscid, and partakes somewhat of the character of bird-lime. When cold, it is hard and brittle. Without wishing in the slightest degree to throw doubt or discredit on the many and valuable experiments made, we would suggest that good samples be collected and treated in the same manner as recommended for gutta percha. We have no doubt that many a parcel of what would otherwise be *good* gutta percha, is spoilt through not being well boiled *immediately* after collection from the tree. At present this is the only way in which we see there is a possibility of ascertaining whether this product can be utilized, and we have the more hope from the fact that the structural character has led the plant to be placed in the same genus as the true gutta percha—structural affinity agreeing so often to chemical affinity.

There are in India other nearly allied *Sapotaceæ* which deserve attention in order to ascertain whether any of them yield a milky juice likely to be of commercial use. Amongst the *Euphorbiaceæ* there are two plants worthy of notice. The *Euphorbia cattimandoo*, found in various parts of India, was first brought to notice by the Hon'ble W. Elliot, and a prize medal was awarded for this substance by the jurors of the 1851 Exhibition. This spiny Euphorb grows to the size of a shrub or small tree, and the milk flows out freely when a branch is cut. The natives use it as a cement to fasten knives in handles, &c. Under the influence of heat it becomes soft and viscid, and when dry very brittle. The *Euphorbia tirucalli*, the milk hedge or Indian tree spurge, is a succulent unarmed plant attaining a height of 20 feet, and its inspissated milk is used for various—chiefly medicinal—purposes, and has been recommended as a gutta percha substitute; but, like gum *Euphorbium*, it has a very acrid character, and the collection is a very dangerous operation to the eyes.

Alstonia or Pala gum is obtained from the *Alstonia scholaris* (R. Brown) of the Natural Order *Apocynaceæ*. The tree is found in India and Ceylon, and attains a height of 50 feet; the wood and bark are much valued for their medicinal qualities. The milky juice which the tree yields abundantly was first, it seems, recommended as a gutta percha substitute by Mr. Ondaartjee who brought it before the Society of Arts in 1864; it seems well worthy of examination.

Mudar gum is the produce of the *Calatropis gigantea* which grows to a height of 6 to 10 feet. The average trees yield a gutta-like substance which becomes flexible in water, and in other ways behaves like gutta percha. In Ceylon there are many *Sapotaceæ* nearly allied to the true gutta percha, but nothing has ever been done, it seems, to collect and prepare specimens so as to judge of their value. As to whether any of these Pseudo-guttas can be utilized (save and except Balata, which has an assured value of its own) remains to be answered. The remarks concerning Pauchontee and its preparation is equally applicable to them all, and we should be happy to receive from any of our correspondents any such samples.

ALOE FIBRE EXPERIMENTS.

THE aloe, vernacular Kinva, *Agave Americana*, grows freely over most parts of Northern India. It is very hardy, attaining a favorable development under the varying conditions of heat, cold, drought, and moisture; this is particularly noticeable in the lower hills, where the plant grows in places in which it would seem impossible to derive moisture save from rainfall, the scanty vegetation in the Punjab Siwaliks having reduced the hygroscopic power of the soil to almost a minimum. Yet amongst boulders, bare and arid sand, out of clefts in the conglomerate and freestone which "crop out" considerably in these hills, the aloe vegetates with ease. It will also grow in the Kangra Valley and Lower Himalayas up to 4,000 to 5,000 feet above sea level. It is an excellent hedge plant, impenetrable by man or beast, all animals having a wholesome horror of its sharp spear-like points. For fences and enclosures of all kinds, nothing could surpass it, and it is a question whether for railways on this side of India, aloe would not be cheaper than wire fencing, the only drawback being its slow growth, and the time it takes to form a good stiff barrier. As a *natural defensive* element in a system of permanent fortification, aloe would, it is believed, be of great service, especially when planted out at the "foot of the glacis" along the bottom of the ditch, and on the superior and exterior slopes of the parapets. A post or armed work so environed would be safe from any attempt to carry it by escalade, the boldest form,—even a *Ghazi*, well primed and let off at high pressure—would think twice before attempting to force his way through a *chevaux de frise* composed of *Agave Americana*. The aloe does not suffer like the *Cactus Indicus* from the attacks of the cochineal insect, and, owing to the large amount of sap in the stalks, an aloe hedge could not be ignited or fired by shell, carcass, rocket, &c.; projectiles could only make a clean round hole through the stalks, which would in a great measure mitigate the murderous effect of splinters from shrapnel and shell.

The preparation and use of aloe fibre seems to have been understood in most countries where the plant is met with. Royle relates that in Mexico Humboldt saw a suspension bridge 131' span, the main cables of which were of aloe fibre 4" diameter. In South America, Spain, Southern Italy, Algeria, the inhabitants of these countries turn the fibre of the aloe into various uses, such as cloth, mats, rope, paper, fishing lines, &c. When twisted into rope, aloe fibre possesses great strength, and will compare favorably with "Sanu"—*Crotalaria juncea*. Dr. Royle in his excellent work "The Fibrous Plants of India," says that, in a trial made at Calcutta, a rope of aloe fibre 3" circumference broke with a weight of 2,519lbs., whilst ropes made of "coir," hemp, and jute, similar in every respect, broke with weights of 2,175; 2,269; 2,456lbs, respectively. In an experiment made at Paris with Algerian aloe and hemp, both ropes being of equal dimensions, the former broke under a weight of 2,000 kilogrammes, and the latter with a weight of only 400 kilogrammes, 1 kilogramme=2·2046lbs. Dr. Royle also mentions an experiment made at Toulon Dockyard, where two ropes, one of hemp and the other of aloe, were tested, after a six months' immersion in sea water. The former only bore a weight of 2,538lbs., whilst the latter *carried* a weight=3,810lbs., showing a clear surplus of strength of 1,272lbs in favour of the aloe or pita.

On the other hand a trial is quoted, made at Madras Arsenal, where a coil of aloe rope was received at the Arsenal, immersed in a tub of water for 24 hours and then exposed to the open air, and after a few showers of rain, was found to be quite rotten. The same results were obtained after similar trials on various ships in the Royal Navy.

Kahars and water-carriers make rope of this fibre in the Punjab. It stands moisture fairly, and has one great advantage, *viz*, that, bulk for bulk, it is lighter than hemp or *Musa textilis*.

During the early part of the year the writer of this paper endeavoured to see if the stalks of plantain, *Musa paradisiaca*, could not be utilised for paper stuff or rope. A certain quantity of plantain fibre was prepared and tried, but it was disappointing to find that it was excessively weak; it would not stand "heckling;" the long, soft, silk-like fibre, 36" to 48" long, would snap and tear, even when drawn through the teeth of a fine hair comb. Care was taken not to *steep* the fibres at all. The operation was as follows:—The long stalk was cut into lengths of four feet, and divided into four by two cuts, at right angles to each other, passing down the axis or peduncle of the plant. The sheaths or lengths of stalk were then passed between the *iron* rollers of a small sugar mill. One operation of this kind was quite sufficient. The strips of bark or more strictly speaking sheaths, were next laid on a clean washed board held in the left hand, and the operator, with a blunt piece of flat iron, or the back of a pruning knife, held in the right hand, firmly, though gently scraped off the green pulp and herbaceous matter. The strip was then turned over and scraped on the other side. When perfectly free from pulp and other substances, the strips of fibre were shaken and washed rapidly under a jet of water, put up to dry in the wind, and again taken down, slightly damped, and the fibres drawn out. After this they were finally dried and ready for packing.

The great drawback to the country plantain fibre is its extreme delicacy and fragile nature, which of course enhances the cost of production. Some specimens were sent down to Calcutta to Messrs Ahmuty & Co., asking what price the fibre might fetch in the market. Their reply was discouraging, inasmuch as they gave it as their opinion that fibre of the description sent would not realise more than Rs. 2-8 to Rs. 3 per maund in Calcutta. Supposing that the introduction into Upper India of the *Musa textilis*, or even a plaintain yielding a fibre superior to the *Musa sapeentum*, were possible, it may not be unprofitable to ascertain what the fibre would cost, say, landed in Bombay or Kurrachee. There are no means, unfortunately, existing in India by which the cost of production of plantain fibre can be determined, such an industry being unknown, certainly in the Punjab. But assuming (1) the fibre to be good, and (2) that the cost of cultivation is more than covered by the value of the fruit—we have all the stalks and resulting fibre to the good. To make the concern pay, the working establishment would have to stand at not less than the following strength:—

Two men to cut up and slice the stalks; 3 boys to carry the stalks to the mill; 1 pair of bullocks to work the mill; 2 boys to attend and serve the mill, as well as to distribute the fibre to 15 women who would wash, scrape, and clean, each, 10lbs of fibre per diem.—

$\therefore$ 10 × 15 = 150lbs.

Daily working expenses would stand at—

					Rs.	A.	P.
1 pair of bullocks					0	8	0
2 men @ 2·5 as.					0	5	0
5 boys @ 1·5					0	7	6
15 women @ 2 as.					1	14	0
					3	2	6
	Rs.	A.	P.				
Drying and packing ...	0	4	0				
Freight to Sea Port ...	1	12	0	...	2	0	0
					5	2	6
Contingencies					0	5	0
				Rs.	5	7	6

$\therefore \frac{2240}{150} = 14{\cdot}21$, and $14{\cdot}21 \times 5{\cdot}5$ Rs $= 78{\cdot}15$ Rs., or in round numbers £8 per ton. The West Indian fibre has been delivered in England at a price varying from £10 to £11 per ton.

Plantain fibre not proving a success, attention was turned to aloe *Agave Americana*, and, on a grant from the District Fund Committee being received, experiments were commenced with a view to ascertain the cost of production, the value, and quality, of the fibre. The process of preparing and cleaning the fibre was in almost every respect similar to that adopted for plantain. The long leaves were cut off close to the stem, tied in bundles of 50 and 60 each, and brought up to the mill; they were then passed between the rollers, two and two together, and laid down on a trestle table close by. After a certain number of bundles had been thus dealt with, the crushed stalks were taken up again and passed a second time through the mill. The second operation completely expressed the fœtid and unpleasantly odoriferous sap, as well as breaking the outer cuticle of the leaves. This sap blisters and irritates the skin considerably, and will produce a serious inflamation of the eye, should a stray drop chance to find its way into that organ; this had to be guarded against, and until the workmen had anointed their arms, legs, and chests with oil, they never set to work. After having passed through the mill a second time, the stalks were taken up and scraped with a *blunt* knife, to remove as far as possible the green pulp and herbaceous matter, after which the stalks were tied up in convenient sized bundles, taken off to the banks of a "toba" (*kutcha* tank), and buried in wet sand for four or five days. On the fourth day the bundles were taken out, washed in a running stream, lightly beaten with a wooden maul or beater, washed and beaten again, and washed the third time. After the third beating and washing, the fibre was clean and of a dull yellowish color. The bundles were then hung up to dry in the shade, but exposed to the wind; during drying the fibre gained the silky white appearance which in Mexico and South America has gained for it the name of "silk grass." The next process was that of "heckling." Heckles, the writer had none, but was obliged to resort to the local market. Two were consequently made up, but the only contrivance which indigenous *art* was capable of producing, was an instrument bearing a close resemblance to a small garden rake; it was certainly better suited for the purpose of "rippling" flax or hemp, than that of heckling a fine fibre; moreover the temper of the metal teeth was inferior, and in drawing the "strick" or lock through the comb, the teeth gave and bent, causing a great waste of long staple, the greater part being left as tow or codilla. Samples of fibre, twisted rope, and tow, were sent to the Calcutta Chamber of Commerce for a professional opinion. The following extract from the proceedings of the November meeting of the Agricultural and Horticultural Society of India shows what chance the fibre has of succeeding as an article of commerce:—

Mr. W. H. Cogswell, a member of the fibre Committee, gives the following report on the above samples, Mr S. H. Robinson concurring: "With reference to the samples herewith, alluded to in the foregoing memorandum, I beg to observe that the washed and heckled fibre prepared from the *Agave Americana*, or common aloe, is about the best I have seen, being beautifully clean, and well freed from the bark or outer skin of the plant; of good colour, there being but a very slight tinge of greenish which it is impossible to thoroughly eradicate without extra steeping, or the addition of chemicals, to the injury of the

fibre; it is of very great length, and fair strength, and a really good commercial commodity, its value to-day being about Rs. 8 a bazaar maund. The samples unheckled I would value at Re. 1 per maund less. The samples of combings, generally known as tow, could be used in this country for paper-making only, its value as such being about Rs. 3 per maund; but in England, where spinning machinery can be applied to it, a good yarn might be produced. As a produce for shipment thereto, it is of greater value than being consumed locally for paper-making: for the latter, I am of opinion it is too good and costly, as jute, tow, and such like fabrics, are so cheap and plentiful in this country."

In preparing the fibre there were sundry difficulties to be overcome; the operators were new to the work, they had never seen fibre prepared from aloes before. The sharp points pricked their hands, the fœtid offensive looking juice was found to be a painfully powerful rubefacient. The mill rollers were *iron* and *not wood*. The motive power, instead of a pair of bullocks, consisted of two "Sainis" working at the end of a horizontal lever, and the resistance to be overcome was sometimes considerable, which meant that the two Sainis had to exert considerable muscular force. These were considerable prejudices in the eyes of the Aryan brother, and took time to tone down. Also, it was only experience which shewed the proper amount of "retting" in wet sand and the degree and duration of beating required to finally separate the green pulp from the fibres. The rollers of the mill used in these experiments were vertical. A system of horizontal rollers in an iron framing, worked by belting from overhead gearing, would give better results; the shafting to be fitted with a fast and loose pulley, so as to throw the mill out of gear when not required for work.

The question of motive-power next demands consideration. The motive-power available in India is—bullocks, water, steam, and wind. Bullocks would not be economical for many reasons. Water is not always to be had, except near canals or close under the hills. So that it resolves itself into a matter between steam and wind. Steam means the employment of skilled labour and a plentiful supply of good fuel. In Upper India, coal, any distance from a railway, is too dear to be thought of; wood is seldom to be had under four maunds per rupee, and the only other substance available is grass or straw. In the "Khandi" or submontane tracts there are thousands of acres of land covered with long grass—*Saccharum sara*, *S. spontaneum*, *Andropogon involutum*,—which would serve as excellent fuel in any engine fitted up with a large fire box and one of Messrs. Head and Schemidth's patent straw burning apparatus; 20lbs to 22lbs of grass being fully equal, in calorific effect, to 6 lbs of best Welsh or Newcastle coal. One of Messrs. Ransome Sims and Head's* 10 H. P. engines, working at a high rate of expansion, and fitted up with the most recent improvements, would in a working day of 8 hours consume $8 \times 10 \times 22 = 1{,}760$, or in round numbers 1,800lbs. of grass fuel. This grass sells for 16 loads of about 30 seers each, for 1 rupee; the daily consumption of grass would not at this rate exceed two rupees per diem.

With regard to wind power, we have in India a vast natural agent almost wholly unutilised, as there is seldom a day in which we have not wind enough to propel machinery, provided suitable gearing and apparatus be forthcoming. A wind mill having a sail area of 500 square feet, would, under a wind velocity=14·67', or 10 miles per hour, give a useful effect of about 11 H. P.

By the following Formula, $H.P. = \frac{A v^3}{1080000}$

where A=Total sail area.

V=Wind velocity, in feet, per second.

$H.P. = \frac{500 \times 14{\cdot}67^3}{1080000} = 14$. Allowing 80 per cent only for useful effect we have 11·20 H. P.

Each such wind machine could work four mills, each mill consisting of a pair of rollers 3' long, 1' diameter; and the amount of skilled supervision required would be almost *nil*. One boy or man to oil and lubricate the bearings would be ample.

With regard to the yield per acre of an aloe *plantation*, the following were some calculations made:—

One acre would hold 1,000 plants, each plant would give 1·5 lbs of fibre.

Supposing acreage of plantation,=1,000 ∴ $\frac{1000 \times 1000 \times 1{\cdot}5}{80} = 18{,}750$ maunds.

Of this amount 60 per cent would be fibre suitable for yarn, rope, &c., and the remainder, 7,500 maunds, a material fit for tow and paper.

Then—

				Rs.
Cost of production of 11,250 maunds		@ 6·5	per maund	73.125
Carriage to sea port of	,, ,,	@ 1·0	,,	11,250
Carriage to sea port of 7,500	,,	@ 1·0	,,	7,500
				Rs. 91,875

This would fetch, according to valuation given in a former para, as follows:—

			Rs.
11,250	maunds of long staple at Rs. 8 per maund	...	90,000
7,500	,, tow &c, at ,, 3 ,,	...	22,500
	Total	...	Rs. 1,12,500

According to this, the surplus of receipts over expenditure would equal about Rs. 20,000. In this calculation the cost of production has been taken at a maximum, and with suitable appliances this should not exceed Rs. 6·25 or 6·0 per maund.

Would cultivation improve the quality and yield of the fibre? Hemp, flax, &c, have been improved in India by judicious cultivation. The yield and quality of cereals depend on the care bestowed on the plants. Napoleon *Ière's* "Edict" prohibiting the import of English sugar &c. into France and other continental countries, however short-sighted a measure in itself, had one result—it compelled the growers of beetroot in France to devote their energies to develope the cultivation of that plant, and it ended in their raising its percentage of saccharine matter, from 5, to 10 and 11 per cent. With these facts before us, it is not too much to anticipate similar beneficial results in the case of the aloe.

Deboisement and destruction of forests seem to go hand in hand with civilization, in India as well as in other countries, and would seem to be one of the unqualified (?) benefits inseparable from the introduction of British rule. And even if nothing else were to be done to reboise the Lower Himalayas, perhaps long deep zones of aloe, planted along some of the present bare and desolate "Revers" of the Punjab Siwaliks, would do a great deal to check, if not wholly mitigate, the terrible evil which threatens to make certain parts of this glorious province as bare and wild as the Sahara itself.

Before concluding, it might be as well to remark that in Mexico the aloe sap is evaporated, and the residual substance used as soap. Also, further experiments might show that the green sap is capable of being used as a dye.

Annexed is a memo. showing some trials made with a view to ascertain the breaking strain of aloe rope—

Rope used was 1·5" circumference

			lbs.
Trial No. I	It was loaded, and broke with	...	587
,, II	,, ,, ,,	...	890
,, III	,, ,, ,,	...	728

There was a wide difference between each result, and these trials were not accepted as conclusive, on that account. The rope was of three strands, laid up by a "sainsar" or native rope-maker, and twisted by a small English rope twisting machine. After trial No. I., the rope was carefully examined, and the point of fracture in the three strands was found *not* to be in the same horizontal plane. The portion subjected to strain was cut off and the weight suspended from the other end. On the second trial the fracture of all three strands was simultaneous, and in the same horizontal plane. In Trial No. III, a fresh portion of rope was used, and, as stated before, gave way under a strain of 728lbs or 9 maunds. Again the three strands did not part simultaneously. According to the best authorities the breaking strain for ordinary rope is expressed by the formula—

$B = C^2 \times 2$ (B being breaking weight, in tons) which would, with the rope used, give us about 1,000lbs. Trial No. II. gave results approximating the closest to this theoretical value.

NOTE.—*It is not overstating the fact by remarking that this eminent firm stand, by general excellence of workmanship, durability, and economy in actual performance, to have brought their steam machinery for agricultural purposes as near perfection as possible. They seem to have left most other competitors in this branch of the profession a long way behind.

EDITORIAL NOTES.

The prospects of the spring harvest, according to the latest accounts are now "good and fair" in almost all parts of the country, and in Northern India have been somewhat improved by the recent rain. The following is the official report for the week ended 22nd ultimo:—

General, though for the most part moderate, rain fell during the week in the North-Western Provinces and Oudh and the Punjab, and has done good, especially in the latter province. Slight showers are also reported from some districts of the Central Provinces and a few States in Central India. Elsewhere there was little or no rain. More is needed in many districts in Bengal, where, however, the prospects of the crops are, almost without exception, promising. In parts of the North-Western Provinces and Oudh, as mentioned in previous reports, the unirrigated spring crops have suffered severely.

The unirrigated *rubi* has suffered especially in Rai Bareily, but in other places where the harvest has begun, the pressure of distress has been relieved. Prices generally in the North-West seem stationary, with the exception of a slight fall in some districts. We regret to note that cattle disease continues in Kumaon and has made its appearance in Lucknow. The accounts from the Indigo districts of Bengal are not so good as last year. Messrs. Moran & Co., in their last report tell us the October plant in Lower Bengal is "not well spoken of," but that it would now be much benefited by rain.

Since our article on Coffee leaf-disease was in type, we have received Professor Stevenson Macadam's report on the subject. It so clearly justifies what we have said that we have found room for it in another column, *in extenso*.

In our October number of last year, page 284, are two short notes on Asiatic and African Caoutchouc, respectively. We extracted these, if we remember aright, from the Ceylon papers. But a correspondent has since pointed out to us that the whole of the matter has been taken from the "Report on the Caoutchouc of Commerce," made to the then Secretary of State for India, by Mr. James Collins, F.B.S., and published in 1872. We regret to see, however, that Mr. Collins' name is not once mentioned in the notes above referred to, nor does anything occur to show the source whence the information was derived. But what is still more lamentable is the supineness of the Indian Government in not circulating copies of Mr. Collins' Report in this country for whose use it was specially intended and where it would have proved so valuable an adjunct to the literature extant on agricultural topics. We fear, however, this is all of a piece with the apathetic indifference and

want of intelligent interest in respect of agricultural matters, that has all along characterised our rule in India. Such a state of affairs is the more to be regretted inasmuch as India is so essentially agricultural a country, if our rulers would but open their eyes to the fact. But the Government prefer keeping information piled up in cellars; and so, often, work is done over and over again,—and who pays the piper? Still, this is no reason why Mr. Collins should not be accorded the well-deserved merits that attach to his labours on the subject of Caoutchouc and its acclimatization in India Among the latest of this able and experienced writer's contributions to the literature of agriculture and commerce are the two valuable articles on Gutta Percha—a subject on which Mr. Collins is eminently qualified to speak—which have found a place in the editorial columns of the last two issues of this journal, as our readers must be aware.

We would call the attention of Government and the municipalities of our various large towns and centres of population to the important and exceedingly interesting paper on "Town Sewage" which appeared in the editorial columns of our last issue. It was kindly placed at our disposal by an esteemed correspondent, and it will be seen at once from the thoroughly practical way in which he deals with his subject, that it is a matter with which he is intimately acquainted. Indeed, the great value of the papers seems to us to lie in its thoroughly practical turn. Our correspondent is in fact a professional Engineer, and as such, his opinions are entitled to all consideration, and cannot fail to command respect. An extract from his private letter to us which accompanied the paper in question, will interest our readers; we only regret having overlooked it in our last issue. Our correspondent writes :—" I am this day sending " you a few remarks on 'Town Sewage' and its utilization, for " which you may perhaps be able to find space in the columns of " your valuable journal. The subject is one of considerable " importance, and in India where the natural conditions are highly " favorable to the extensive utilization of town sewage, the time " has in my opinion fully come when Government should step " in and *insist* that municipalities should devise and carry " out, each in their respective towns, some rational method of " disposing of their sewage to the best possible advantage. But " I am afraid we are not likely to see such a state of things " brought about until we have a Minister of Agriculture with " a seat in Council, and supreme at the head of a properly " organised Department. We give the Aryan brother education " on most subjects, but it would be more practical if we " taught him how to fill his stomach and turn to better use " the fruits of the Earth and to develope the resources of the " wonderful soil with which God in His great bounty has " endowed this country."

We have ourselves, on various occasions, of late drawn attention to the increasing importance of this question of the useful disposition of town sewage, and have at all times been glad to encourage any steps taken in a right direction with this end in view: we cordially endorse the above remarks of our correspondent. In reply to his letter we wrote to him privately, and while agreeing in all or nearly all he said, we pointed out the difficulty (which had already been witnessed in Allahabad and other parts) in the shape of caste prejudice among the natives which might stand in the way of a largely extended or universal adaptation of town sewage to agricultural purposes in this country. We were glad to receive our correspondent's re-assuring reply :—

" *Apropos* of town sewage," he said, "I may state that the " 'Araine' or Mussulman market gardeners have no prejudice or " objection to use this fertilizer, and are only too glad to get it. " It is generally distributed by gravitation, but in many places, " wells or pits are dug, and it is baled out by "Dhiuklis" into the " fields. The 'Sainis,' or Hindoo market gardeners, sometimes use " it, only not so freely as their Mussulman *confrères*. I once " attempted to induce a Mussulman native gentleman to apply " it to his sugarcane, but he said that he personally had no " objection to it, but Hindus would not take it, nor could he " get a sale for the resulting molasses or *gur*, as it (town " sewage) imparted an unpleasant taste to the raw cane; " moreover, the juice though plentiful was watery and deficient " in saccharine matter. He admitted, however, that no other " manure had been given to the crop during a small trial he once " made which would of course account for the failure; also the " there had been very heavy rains that year, and the sewage he " used had been largely adulterated with storm water."

These statements confirm the intelligence received some months ago from Poona and Umritsur, in both which important towns the experiment of utilising night-soil as a manure, either in the shape of poudrette or in a liquid state, has met with great success, the ryots availing themselves eagerly of its advantages. And thus it is that prejudice will ever fall down before self-interest. The success of the experiments at Poona and Umritsur ought to be sufficient to induce the municipalities of our large centres of population to take the matter up at once as a surely profitable undertaking, not to mention the sanitary benefits that would accure. They should commence at once, and not wait for Government to step in and compel them to such action.

A valued correspondent writes to us from Hoshiarpore that a small experimental farm is about to be started there, the project having been drawn up and the cost estimated for one year's working expenses :—" Our model or rather experimental farm has been taken in hand ; the buildings are in course of construction. We intend growing sugar, wheat, maize, cotton, tobacco, *Arachis hypogœa*, and fodder crops such as turnips, kohl rabbi, beans, &c., under a system of judicious rotation. The first crops I am going to put in will be sugarcane, tobacco, and *Arachis hypogœa*. Arrangements will be made to get in the sugar-cane crop before the hot weather sets in. With well irrigation and a good soil, our chances of success are favorable. I may add that an improvement has been effected on the 'Kaiser' plough. I made up one, following Ransome and Sim's pattern known as the 'Primitive' plough; natives like it wonderfully; ordinary cattle can draw it."

We wish our enterprising correspondent all success in his venture. We shall be glad to hear more about his improved plough. The "Kaiser" has hitherto been looked upon as one of the best in the market, the advantages claimed for it being—its extreme simplicity of design and construction, so that it can be repaired by any village blacksmith when damaged ; its lightness, so that it can be drawn by any ordinary pair of cattle; its efficiency,—it can be made to turn up the earth to a depth of twelve inches we are told ; and its trifling cost—only four rupees. This 'Kaiser' plough has been tried very successfully at the Cawnpore farm, and has since, we learn, been introduced with advantage into Mysore by the local Government. He is indeed a benefactor who can surpass these claims.

In another column will be found an important and practical paper on some experiments conducted with aloe fibre, which has been forwarded to us by an esteemed correspondent from whom we shall be glad to hear further. He is in a position to know thoroughly what he writes about, and his paper gives evidence of his not writing as an official who draws his knowledge from a study of blue-books, but as one who understands from practice what he treats of.

The Annual Report of the Bhadgaon Experimental Farm, in Khandesh, for 1879-80, is to hand, and deals with the usual topics. The season was on the whole "a very favourable one ;" there was but little damage done by rats, and the Bhils appear to have been better employed than in giving trouble by grain thefts. At Bhadgaon, as elsewhere, the Bamieh cotton proved a complete failure. The experiments made with this variety in the previous year were likewise, it will be remembered, all failures, the Superintendent attributing it to the soil of Khandesh being "too stiff," and "the heat and rainfall too severe." It is time, therefore, that the experiment were given up ; for the conclusion seems inevitable that though this variety may do well enough under garden cultivation, it is not fit for general sowing. Much attention was paid to raising pedigree seed of acclimatized American varieties of cotton ; and by a careful system of retention, some improvement seems to have been effected, instead of the deterioration which it was supposed had set in in the *Dharwar* variety. But we regret to see that the outturn of clean cotton is again so small. From a total crop of 185 acres,—of which three-quarters was pedigree American, the remainder being made up of the Hinganghat variety with some small plots of Bamieh and other new kinds—the average outturn did not exceed 95lbs. This is certainly better than the result of the previous year's operations, when the outturn was only 69lbs to the acre, but still it seems very small when we remember that in America the average is close on 300lbs. The

Teosinte *(Reana Luxurians)* has succeeded to a certain extent at Bhadgaon, and the cultivators appear to appreciate the plant as a fodder. That it is a palatable forage there is no doubt, but that it can compete with the common *jowar* is very doubtful. Experiments in growing the Ram-Bhendi (*Malacra Capitata*) as a fibre crop resulted in its being proved that it cost nearly three times as much to prepare the fibre, as it would fetch at the mills. There seems little chance of the *Bhendi* ever being able to compete with brown hemp, the quantity of fibre that the washers can extract from the latter being so much larger. Success was obtained in the introduction of potatoes and other English vegetables. In arboriculture, experiments were made with the carob, the rain-tree, the divi-divi, and the cassia florida, with some degree of success. The seeds of the cow-tree (*Brosimum galacto-dendron*) failed to germinate. This useful tree belongs to the natural order *Urticaceæ*, and when wounded, discharges a milky nutritious juice in such abundance as to render it an important object to the poor natives of the Cordilleras. Some attention is paid at Bhadgaon to improving the local breed of cattle and horses, and of raising mules; but nothing very thorough appears to have been the result. Sericulture proved a failure; the tasser worms appear unable to stand the variations of temperature. A further attempt will be made with a view to test the value of the *Lagerstrœmia Indica* as a food plant for the tasser worm, and then it is to be hoped sericultural operations will be made over to an expert from home, as in the N.-W. P., or abandoned altogether.

Mention is again made this year of the aversion of the students obtaining their agricultural education at the farm to such training as would take them out of doors. As we remarked before—how youths are to become practical agriculturists without instruction in the field is beyond our comprehension. But this mild kind of aversion is by no means confined to the Bhadgaon farm, and the explanation seems to be that many young men come forward in numbers under the impression that at the end of their services Government employment would somehow or other be found for them. It says little, alas, for the value placed in the agricultural education obtainable at our "experimental farms;" but it would be well, we think, to remove the above misconception once for all. For we quite agree with the Commissioner when he says that "to turn out mere theoretic farmers unwilling to put their hands to the plough and endure exposure to the season, would be misdirected energy—useless even if successful." We had an excellent illustration of the average intelligence of these "theoretic farmers" in the person of the gentleman who conducted some experiments with new ploughs in the Trichinopoly district the other day.

A FEW months back a rumour prevailed in Assam that Government was about to undertake a systematic survey of the Khasia and Jaintia hills, the investigation to consist of all branches, geological, botanical, and Archæological. A botanical exploration of the hills including the Garrow and Mecher country would, to a certainty, result in bringing to light plants of numerous and rare varieties, in such quantities as would astonish the botanical world; but the drawback to making a perfect collection is that the work must be pursued throughout the rains; for most of the hybridised orchids, lilies, &c., flower only in the months of June, July, and August, and many a man whose botanical knowledge enables him to identify plants by the leaves and bulbs only, would, unless he saw and preserved the flower, be induced to append names to specimens that would turn out most startlingly different. It would be necessary for the botanist to prosecute his work in person; for Khasias, though willing enough to engage in collecting plants, cannot be made to understand that any that do not possess gaudy and large flowers, can be of use. Hence, there are plants valuable as febrifuges and possessing other medicinal and economic properties (fibres especially) that escape notice from being burnt up at the time when it is considered healthy to travel in the hills off the line of road. In many parts of the hills, if precautions are taken against the effects of a daily drenching, the explorer's health will be unaffected, provided he is a man of ordinary robust constitution; but unfortunately, in those localities where from the dense nature of the forest the most valuable plants would be found, the climate will be found most trying to anyone not inured to jungle life. Yet, to do the work thoroughly, the moist changeful climate must be faced; for it must be borne in mind that the search for plants will entail the exploration of the whole country, and the botanist must be down in a hot steamy ravine one day and have to encounter the chilling blasts of the monsoon, with drifting rain on high ridges, the next. Government at one time did establish a cinchona garden on the edge of the Jyrung forest, below the Nongklow bungalow, but the gentleman in charge (the late Mr. Bierman of the Botanical Gardens) suffered so severely from fever, as did also his subordinates, that the prosecution of the scheme was abandoned.

IT may not be generally known that along the edge of the northern forest surface of these hills, at an elevation of some 4,000 feet, the ipecacuanha plant is indigenous; that near the Kollong rock, a short distance to the west of the old Assam road, between Myrung and Nongklow, a tuber resembling very much the salap-misree of Central Asia is found; and the Syntengs, in the neighbourhood of old trees, dig out a coarse though palatable truffle. One of the most lamentable mistakes made by the Assam Government was the selection of the bleak exposed site for the farm. The district officers were to blame for this, as the Farm Superintendent himself, so he asserts, protested against the place as unsuitable. Three miles from the station, on the Jawai road, plenty of good land is available, but of all places that would, we feel certain, prove successful, is the large stretch of meadow land lying north of the Maodmai inspection huts. This land is sufficiently clear of stone to permit the use of ploughs, and in many places reaping machines as well, while the sleek appearance of the cattle indicates how suitable the locality is for the rearing of live stock. Some are of opinion that sheep and imported cattle would suffer from foot-rot, but we have made particular enquiries and find the disease unknown. If ever the Assam Government finds itself in a position to afford the resuscitation of an experimental farm, a trial of Maodmai should be made. Farther again to the eastward, about five miles from Jawai, lies another stretch of prairie land, in the middle of which a large tank has been excavated; and although this place may possibly be within the rain belt, the cultivation round about shews that it would produce wheat and barley, grown as cold weather crops, while what is left of the forest proves the suitability of the site for the planting of timber and the hardier fruit trees.

IN Calcutta, as elsewhere, the salutary effects of holding annual flower and vegetable shows, where prizes are awarded to successful competitors, is becoming more widely recognized; and no better practical illustration of this could be desired than the splendid specimens of flowers and vegetables that are exhibited every year at the shows held under the auspices of the Agri-Horticultural Society. The flower show held in the gardens of this Society on the 3rd ultimo, under the distinguished patronage of his Excellency the Viceroy, Lady Ripon, and his Honor the Lieutenant-Governor of Bengal, was unquestionably the best yet held. The collection of both flowers and plants was not only numerous but rare; and credit is due to the Society's gardener for the care and good taste displayed in the arrangement. Prizes were awarded for the best collections of camelias, roses, begonias, verbenas, asters, heartsease, phloxes, portulacas, pinks, crotons, dracænas, geraniums, ferns, lycopods, and new and rare plants. Besides the above there was a very fair exhibition of petonias, tropæolum, cacti, and annuals. The show, which opened at 3 P.M. and lasted till dusk, was visited by an unusually large number of the rank and fashion of the city.

ALL persons interested in botanical pursuits, says the *Pioneer*, will be glad to learn that considerable progress has been made in the preparation of the material for the unpublished portions of the *Flora of British India*. All the Orders down to Gentianaceæ are ready for publication; Dr. Watt has written the Primulaceæ; Mr. Phistleton Dyer, the Apocynaceæ and Asclepiandaceæ; and Dr. Hooker the Compositæ. The other Orders have been written by Dr. C. B. Clarke, so well known for his previous good work in Indian botany and as editor of the reprint of Dr. Roxburg's *Flora Indica*, published a few years ago in Calcutta. There is now some hope of this great work being completed during the life-time of the present generation.

A curious memorial, of which we have been favoured with a copy, has just been submitted to the Governor of Madras. The students of the Saidapet Agricultural College have a grievance. It is not that they have any complaint against their teachers, or that the instruction afforded them does not come up to the standard which they think they have a right to expect. They admit, indeed, that they are deeply indebted to Government for providing them, at a considerable cost—we follow the words of the memorial—with the means of acquiring so much useful and practical knowledge. What they learn, they aver, "is not only pleasurable in the abstract, but the subjects of study, besides securing an intellectual training which is not inferior to that given in other technical educational institutions in India, furnish ample means of increasing individual and national wealth." And still they are not happy, but "with a grateful acknowledgment of the rich benefits received from the Government," they beg of his Excellency Mr. Adam "a slight extension of these favours." What the souls of the students of the Saidapet Agricultural College yearn after is—a title! While they "most readily acknowledge the superior advantages of a really useful instruction" which will enable them "to pursue independent and respectable paths of life," the unfortunate young men are "unable to avoid the painful consciousness that it does not confer the least social significance." They point out enviously that in the Medical College Madras, before its affiliation to the University, the successful candidates were designated as G.M.M.C.; those of the Bombay Medical College, in the same way, were styled G.G.M.C.;" and they pray Mr. Adam to grant them, along with their diplomas, the privilege of appending to their names "titles similar to those granted in other institutions under like circumstances." The memorial is signed by twenty-three "late students" and thirty "present students" of the College, of whom eight of the former and nine of the latter hail from the Bombay Presidency: these are chiefly Parsees. The prayer of the memorialists is not a very formidable one, and we see no particular reason why, if it pleases them, they should not be allowed to write the "title" of G.S.A.C. after their names.

The proposed exhibition of agricultural produce, cattle, and implements that is to be held this month at Lucknow, is intended specially to excite interest in the improvement of agriculture in Oudh, and to, if possible, initiate some decided action in this direction amongst the talukdars. It will be held under the auspices of the Talukdars' Association, and theoretically, is but a mere adjunct to a conference of members of the Association for the purpose of discussing any and every mode of improving the agricultural system of this country. India is, however, hardly ripe for Social Science Congresses and similar opportunities of riding out special hobbies, and it may safely be predicted that the main interest will centre in the show of cattle, agricultural implements (old and new fashioned), and samples of produce, either the long-established staple of the country, or some newly introduced fodder or fibre. The exhibition is, as we have stated, chiefly intended for Oudh; but it will be supplemented by an exhibition of the ornamental ware manufactured in the N.-W. P., and also by a contribution from the Department of Agriculture and Commerce, which will take this opportunity of placing more prominently before the public its suggestions and proposals for the improvement of agriculture.

Our Agra contemporary remarking on the agricultural prospects of Upper India, says:—

Six months ago alarm was justly excited at the failure of the rains in the second half of the Monsoon, and gloomy forebodings of approaching scarcity set in. We are now approaching the end of the cold season, and can judge how happily those forecasts have been belied. In the first place the crop of cotton has been an unusually heavy one, the early rains in June and the absence of them in August and September having apparently developed the plant to its highest perfection. Up to date the value of the staple exported from Agra alone exceeds half a million sterling, more than enough to pay the land revenue of three districts; and yet further receipts for the next three months are expected. In regard to the other rain crops it would have been unreasonable to have expected similar results, but the winter ones seem to be as flourishing as usual, though they were sown without rain and have had none to speak of since. Contracts are already being made for the delivery of wheat at 19 seers, and gram at 28 seers, per rupee—prices low enough to make the British farmer quake when he reflects that they are the quotations for a comparatively [illegible] year. The fact is that the agriculture of Northern India is gradually being emancipated from that entire dependence on the rains which has been its greatest drawback. The spectacle of the Punjab, where enormous crops of wheat are raised almost without any rainfall, is a proof that there is nothing in the nature of things to prevent the N.-W. P. and Oudh from doing the same. It is only a question of wells and irrigation, and these wants are being gradually supplied.

The experiment of farming out cattle pounds has been tried in ten districts of Bengal, with the financial result of an increase of 59 per cent in the average annual profit. This result appears to Sir Ashley Eden to be most satisfactory and to have been gained without any additional burden being imposed on the people. His Honour is evidently no believer in the maxim, *ex nihilo nihil fit;* but adduces no better argument in support of his views than that complaints are now frequently made by the lessees that fewer cattle are impounded by the police than formerly. He sees no reason why the farming system should not be as capable of general extension, and succeed in the end as well, in the case of pounds as in that of ferries. The classes likely to take leases of pounds are far more numerous than the class who take leases of ferries, and competion will therefore be greater. The local authorities have therefore been called on to report whether they can recommend the introduction of the system into the districts under their charge. The system should not, Sir Ashley Eden thinks, be introduced anywhere unless the ryots are able to take care of themselves, and to complain of oppression on the part of the lessees.

The following information regarding artificial indigo, from a well-informed quarter at home, should be re-assuring to the indigo interest—"In the first place, it is not intended to supersede natural indigo, but simply to produce a new 'fashion color,' for the purpose of *Hautes Nouveautés*, where indigo, so to say, is not used and another color does just as well, which, if not so real, is, however, more easily employed, and for a perishable color is paid dearer than natural indigo. Up to the present time not quite two pounds in weight of this artificial produce have been made (not the slightest fulcrum exists as to its cost,) but ultimately, in the course of years, the manufactory in question hopes to be able to supply two or three of the largest printers with its produce; but we think that even after the realisation of the eventualities, the consumption of indigo will neither materially decrease, nor will there be much change in prices."

Mr. Petley, the gentleman who has recently succeeded in producing tea for the Rangoon market at Tonghoo, has, according to the Commissioner of Tenasserim's report, 10,000 young plants doing well. Mr. Petley has likewise some 600 or 700 coffee plants bearing, which were planted about four years ago, and he also seems to have been more successful with cinchona cultivation in the same district than the Forest Department whose legitimate business one would think this cultivation would be. Mr. Petley has about 2000 cinchona trees, of all sizes, some from 18 to 28 feet high, which were planted in 1875. The cinchona plantation at Lakethe in the Tonghoo Hill Tracts, belonging to the Roman Catholic missionaries, is also said to be flourishing. Mr. Petley has likewise raised a crop of about 40,000 lbs of potatoes on the Karen hills, which were readily bought for the use of the European troops at Tonghoo. The Karen potato crops in the same locality were said not to have realised remunerative prices, though Mr. Petley's success in all the cultivation he has undertaken is most encouraging. When the Tonghoo Railway is completed it is to be hoped he will realise considerable profits as a reward for the enterprise he has displayed in a country not remarkable for Europeans stepping out of old grooves to risk their capital in new undertakings.

The Spaniards abroad have a pleasant way of dealing with people who presume to bring indifferent produce to market. In India attempts are made, on the Bombay side, to make the growers of cotton virtuous by enactments against adulteration, or the services of the State are enlisted in relieving merchants of the obligation of seeing for themselves that they receive the actual goods that they agree to buy. In Manilla the Government are still more paternal. The Governor of the province of Camarines Norte has addressed a circular letter to the local authorities, pointing out that in consequence of the hemp grown in that province being so deteriorated in quality there was scarcely any demand for it; there

was a strong probability of its shortly becoming unsaleable, which would cause the misery of many families, and the ruin of the province, as that fibre is the principal cultivated product there. The Governor has consequently ordered the headmen and hemp-growers and dealers to assemble in their respective villages, and has informed them that, by persisting in their present course of badly preparing the fibre, they will be ruined, but that by more careful modes of preparation, they will gain sure profits by the inevitable rise of prices. The growers and dealers have also been informed that if persuasion fails to improve matters the Governor will take stronger measures. The Governor has also ordered the hemp dealing firms in the province not to admit into their storehouses, at any price, inferior hemp but to admit only that of good quality, and has directed them to inform him of the names of persons bringing badly prepared hemp to their store-houses, so that proceedings might be taken against them.

THE following interesting remarks on the mustard plant and mustard seed oil are taken from the *Journal of Applied Science*:—

The mustard plant thrives in California, and grows in such profusion that it becomes a pest to the wheat fields, especially in the coast valleys, as for instance, from Alamoda south to the Santo Cruz and Pajaro basins. It stubbornly resists extinction, and so grows and overtops the grain with its yellow flowers that a stranger might readily mistake it for the crop intended to be raised. A small quantity has always been gathered for table use, it being of excellent quality, but of late years it is found to yield an excellent oil, adapted even to the uses to which olive oil is applied. It is gathered by Chinamen, who thresh and bring the seed to the oil mart in San Francisco, where they dispose of it at two to three cents per pound. Many who have made trial of it prefer this oil to that made from lard or the olive oil, for cooking purposes; it holds out against rancidity longer than the latter. It is also extensively used to adulterate olive oil. Mustard seed oil is sold in the San Francisco market at a dollar the gallon in five gallon cans, and a dollar and a quarter in one-gallon cans.

A CORRESPONDENT sends the following recipe to the *N. B. Agriculturist* as a cure for grass on pavement:—

Some time ago I noticed in your paper a letter from some one inquiring a remedy for the above. I am glad to be able to tell him of something that will put an effectual stop to grass growing in a paved yard for many years to come, if properly applied. Thoroughly root out all grass, and when the ground is perfectly dry, cover it with a very thin coating of coal tar, sweep it with a brush to prevent it running into pools, and immediately throw on sand until it has a uniform covering one inch in thickness; if two inches, all the better. After lying for say, ten days, sweep off all sand which the tar has not absorbed, and the result will be a clean dry yard in all kinds of weather.

ACCORDING to careful calculations made by Mr. H. L. Roth, in a work on the sugar industry, taking the mean of the years 1864 to 1878, according to population, the following was the average consumption of sugar and molasses per head of population in each of the Australian colonies:—

	lbs.
Queensland	92·13
Western Australia	91 50
New South Wales	85 19
Victoria	84 76
Tasmania	78 51
New Zealand	73 18
South Australia	71·31
Average for Australasia	78· 7

In the United Kingdom the average annual consumption is only about 67lbs.

AN American invention, we learn, has been brought out for preserving potatoes so that they will keep sound for years and retain their natural flavour. The operation, we are told, consists in a simple process of applying great pressure to the potatoes, so as to express the moisture. After undergoing compression, the potatoes are, with a view to the same end, put into a driving apparatus, and after every suspicion of moisture has been got out of them in this way, the resulting product is ground into a coarse meal ready for use. Some first shipments of potatoes cured by this method of their septic properties, were made last year to England from California, and met a profitable reception in the English market. It is stated in an American paper that there are 300,000,000 acres of uncultivated land on the Pacific slope eminently adapted for potato growing, and it is said that the only obstacle towards extending potato cultivation in this tract has been the impossibility of finding a suitable market for the product. If the system of preserving potatoes turn out a commercial success, vast potentialities in the way of markets seem to open out to the enterprising growers of the "wondrous root," as Lord Beaconsfield once termed it.

IT is stated that the cultivated area in the United Kingdom has increased by 126,000 acres since 1879; but there were last year nearly 600,000 fewer acres under wheat than in 1870. Oats, beans, peas, and maize are also on the wane, while barley has not increased in quantity. On the whole the area of the corn crop has diminished by 1 per cent since last year, and by 7 per cent during the last ten years. On the other hand, potatoes have increased in the last twelve months by 10,000 acres, and 260,000 additional acres have been laid down as permanent pasture and meadow. There are 5,000 more acres of orchard land now than there were in 1870, and 3,000 more acres of market garden. Woods and plantations have increased 10 per cent since 1872.

MISCELLANEOUS ITEMS.

THE annual exhibition of the Madras Agri-Horticultural Society was held on the 19th ultimo at the "Company's Gardens." The attendance was good, though not perhaps quite as large as on previous occasions. The show of plants was admirable but that of flowers did not come up to the standard of previous years. The show is more and more indebted every year to native gentlemen, for its attractions. The display of ferns by one of these enterprising natives was incomparable.

THEIR third annual Flower Show was held at Dinapore on the 17th ultimo. There was a brilliant display of phloxdrummondi, pelargoniums, geraniums, asters, pinks, pansies, verbenas, violets, and some fine roses. As regards vegetables, the tomatos exhibited by Dr. Griffith were very fine, particularly the greengage and oblong pink varieties. Lettuce, onions and spinach, grown in the hospital gardens by the soldiers, from seed brought from Cabul by Major Home, were a novelty. Great credit is due to Major Home, Colonel May, and Dr. Griffith, for the way in which the arrangements for the Show were carried out.

THE Wadhwan Agricultural Show which opened on the 10th ultimo, and lasted three days appears to have been a great success. The exhibition of live stock was good. Farm produce comprised fruits, vegetables, grains, seeds, fibres, cotton, tobacco, dyes, and forage plants. Several implements and machinery were exhibited, and ploughing matches were held. All the chiefs of Kattiawar, we are told, take great interest in these shows which have done much to improve the breed of horses and cattle and to promote the interests of agriculture generally.

THERE is, we read in the Mysore Administration Report, very little horticulture in the province: a small attempt is made in the Lal-Bagh at Bangalore at cultivation of new varieties of trees, foreign as well as Indian: and the success though not great, is not altogether discouraging. The Superintendent of the Lal-Bagh reports favorably on the present appearance of the manilla and the cocoa plants of more than three years old, and on the newly introduced rubber trees and the *Eucalyptus Saligna* and *E. Citriodora*.

WE see that a movement is on foot for the erection of a Cotton Spinning and Weaving Mill in Lucknow, on the basis of a Joint-stock company. The local paper thinks the very successful working of the Cawnpore Mills justifies this new enterprise. "There is a practically illimitable demand for cotton twist and calico in Oudh, and the promoters see their way clear to supply these everyday essentials at a minimum cost to consumers."

THE Lahore paper of a few days back tells us that a light handy plough of superior construction may now be seen at work on the arable land in the Lawrence Gardens. It has a good English ploughshare, and the wood-work is not unlike the native fashion, but lighter and less clumsy. It has no beam like the native plough, but is merely dragged by a rope attached to the front. As a native plough is at present worked alongside of it, the contrast between the two as to speed, depth, and apparent ease of working is very marked.

THERE are nineteen breweries in India,—3 in Madras, 1 in Bombay, 5 in the North-West Provinces, 5 in the Punjab, 3 in Burmah, and 2 in Mysore. The estimated production of ale, beer, and porter from these breweries, during the year 1879, was 1,569,026 gallons, of which 872,2?6 gallons were purchased by the Bengal Commissariat Department for the consumption of the troops.

A PROFESSOR BAYER of Munich, is the man who is said to have discovered an artificial way of making indigo, "by means of cinnamic acid in a nitro-bromic combination." According to the continental papers which started the story, a manufactory at Mannheim makes the cinnamic acid from tar oil.

THE following is the specification of an invention that has been filed in the North-Western Provinces by Mr. P. P. F. Michea: "For the complete separation and conversion of the indican of the indigo ferca and for increasing thereby, in the presence of alkalies, conjointly with rapid powerful oxydation, the production of indigo."

PAPER-MAKING was unknown in Europe three centuries ago, but in Japan they have made it for over 1,200 years.

THE trade in that useful article the Burmah pony at Rangoon is said just now to be very brisk. During this season the Shans brought down

225 ponies, which were sold through the agency of the Rangoon Pony Mart. The sales realized Rs. 34,200, or an average of Rs. 152 per pony. The demand at Madras appears to be even greater than in Calcutta, though certainly in the latter place the supply is not equal to requirements.

THE *Ceylon Observer* says:—The preparations for the approaching pearl fishery are actively in progress. Sample oysters have been gathered, and agents of Indian merchants are engaging houses at large rents.

AUSTRALIAN seed potatoes are finding their way in large quantities into Calcutta. A trial of these potatoes was made on a small scale, and proved most successful; hence the attempt to introduce tons. Edible potatoes in the North are scarce, while the greatest facilities for raising the esculent are offered both in soil and climate.

THE New Orleans *Times* reports having received from Ruatan three stalks of sugar cane measuring respectively 17 feet 9 inches, 16 feet, and 16 feet. The first had 57 joints, the other two 53 each.

THE manufactories of agricultural implements have doubled in the United States during the last ten years. In 1850 this industry gave employment to 5,361 hands. In 1880 it gives employment to 40,680.

THE cultivation of pampas grass, now so much used for decorative purposes, has become quite a profitable industry in Southern California. Three quarters of an acre planted in pampas grass yielded, at 2½ cents per head, 500 dols. Another grower sold all he could raise at 7½ cents per head. Last year 10,000 heads or plumes of this grass were sold from that region.

A BRILLIANT correspondent of the Putnam (Conn.) *Patriot*, who evidently cares little for agricultural matters, suggests the following themes for discussion by the Farmer's Club of Pomfret:—"Why do not cows sit down to rest the same as dogs? Why does a dog turn round a few times before he lies down? Why does a cow get up from the ground hind end first, and a horse fore end first? Why does a squirrel come down a tree head first; and a cat tail first? Why does a mule kick with his hind foot, and a sheep with its fore foot?"

OFFICIAL PAPER.

MR. MARSHALL WARD'S SECOND REPORT ON COFFEE LEAF-DISEASE.

To the Hon'ble the Colonial Secretary.

SIR,—In preparing the report which I have now the honour to lay before you, my great difficulty is to select from the numerous facts accumulated, so as to place prominently those which appear to have the simplest and weightiest bearing upon the questions to be discussed. It is a source of satisfaction that none of these facts are opposed to the statements already made in my preliminary report, but, on the contrary will aid considerably in understanding them. I am justified not only in further insisting upon what was before brought forward, but also in thinking the newly-opened-up lines of investigation of the utmost importance to the inquiry into the causes of leaf-disease.

My time has been employed partly in the comparative study of various fungus forms occurring on cultivated coffee, and in collecting facts on estates, partly in the closer study of certain selected examples of these forms, in order to come to conclusions as to their real position in the research. I have accumulated much information relative to the soil, climate, and elevation of coffee in Ceylon, and am naturally in a better position to form judgments respecting the various methods of cultivation employed. Observation of the changes undergone by coffee over large areas from time to time is still yielding valuable results. The facts gained by microscopic analysis will be presented below, and are of the utmost importance.

As to the present aspect of the coffee districts south-west of Nuwara Eliya, a recent inspection was encouraging: with a few exceptions the trees were luxuriant in wood, and leaf formed during the moist season of the late monsoon. The wet weather experienced during the earlier months of this year appears to have played a considerable part in producing the dark green appearance of many estates, and it is probably matter for congratulation that a consequent production of leaf and wood has enabled the trees to gather strength and material for the work of next season. The short crop, partly consequent on the growing forth of flower-buds into leafy shoots during the wet weather, will probably tend to the same end, and the trees may be looked upon as having gained by the rest thus afforded them.

I shall have the honour of laying before you, in some detail, numerous experiments and observations, drawing what appears to be legitimate influences from them later: it is too soon to rest satisfied with even the best of these, but the careful securing of each step in advance must prevent hasty judgments on this difficult matter.

One group of these observations is of importance in aiding the diagnosis of leaf-disease, and in this connection will be given reasons for attributing certain appearances, commonly ascribed to the action of *Hemileia vastatrix* to other causes.

Sec. I.—"Pin-spots."

It is generally acknowledged that a severe outburst of the "rust" or spores of *Hemileia* is heralded by the appearance of pale yellow spots; these are often detected only by holding the leaf up to the light, but are sometimes opaque, and have received the popular name of "pin-spots."

¶ 1. Microscopic examination of the substance of the leaf so affected shews some differences, according to the age of the spot, and various minor circumstances. In some cases, where the "spot" is hardly observable, the cells present little difference from those around; in more advanced "pin-spots" there are often brilliant globules of large size, or masses of granular matter. Older spots shew a well-established, branched, coral-like mycelium, quickly spreading into the surrounding tissue. Still later certain branches become aggregated beneath a stomate, grow out together in a mass, and form groups of spores on the exterior.

I have found considerable difference in detail in different parts of the coffee districts, and hope to bring all under some general statement before long. Many coffee leaves present at times pale patches of one softer tissues, which are due to deficiency of green colouring matter merely: the is a phenomenon of the same kind as the "variegated leaf" so common in other cultivated plants. In one case, at least, the application of potash salts appear to have brought back the normal dark colour.

Sec. II.—The Second Spore (Teleutospore.)

¶ 2. In my preliminary report (§ 1) I described a second form of spore of *Hemileia vastatrix*, differing in important points from the well-known papillate spore constituting the main mass of the orange-coloured rust, and I also drew attention to the fact that it produces on germination a four-chambered structure (*promycelium*) whence arise four small *conidia* at the tips of lateral branches. This is not the place to discuss the scientific importance of this discovery; but there are some points of fact which must not be passed over.

The smooth turnip-shaped spore arises late in the history of the disease spot, sometimes not until it has turned brown in the centre: it is produced by the same compacted mass of mycelium which produces the papillate spores, and consequently occurs intermingled with them on the rust patch. This mass of mycelium is constricted into a kind of neck where it passes through the stomate; it then expands into a somewhat conical body which produces the spores from the ends of projections forming its sides and top; in vertical median section the whole presents an appearance something like a *fleur-de-lys*. As the branches grow through the stoma, they appear to fuse laterally, and so form the productive head (*hymenium*). There appear to be no structures comparable to sexual organs.

¶ 3. This smooth, turnip-shaped spore is easily germinated in water, weak sugar solution, or more complex fluids, in all cases producing the same 4-chambered tube whence arise the 4 *conidia*: the tube varies in length according to the nature of the medium. These spores also germinate in the same manner while still attached to the coffee leaf, provided the atmosphere be damp and warm.

I can also get the *conidia* to commence germination in various fluids: in the best examples, however, nothing more than a short delicate tube has been formed. Sometimes, and especially in complex solutions, acicular crystals are deposited on the *conidium*. Though less readily than in pure water, these *conidia* will commence germination on the coffee leaf, but they soon die: I have never seen them germinating on estates. It is remarkable that they appear to form no structure on or in the coffee leaf.

¶ 4. Now there can be no doubt that these *conidia* play some part in the reproduction of the fungus, and it is of the greatest importance that this rôle be established. The smooth turnip-shaped spores which produce them are far commoner than I at first supposed though they occur in much smaller numbers than the papillate spores which constitute the main mass of yellow "rust" I shall give reasons for believing that it is the latter which are the chief agents in reproducing the fungus on coffee.

Sec. III.—The "Filaments."

The greater portion of my time has been occupied with the study of various forms of fungoid growths found on the exterior of the leaves and branches of coffee as spores or filaments. As already stated (prelim. Rep. § 6) there are several different kinds of these, and a comparative examination of them over large areas has shewn that they vary considerably: about half-a-dozen are widely spread, and I have selected four of them as met with everywhere at different times.

¶ 5. It would be tedious and unnecessary to enlarge upon the less commonly occurring forms. Many of them are spores accidentally fallen on the leaves, which do not germinate there; others start a slight growth in the adherent moisture, but not finding suitable media soon die; a few appear to feed on the decaying remains of dead spores, &c., and are somewhat common on old disease spots. Of all these forms, not one shews any signs of doing harm to coffee: they belong chiefly to groups of fungi well known to be capable of living on dead and dying matter, but not able to destroy living plants.

However, from their general occurrence and vigorous growth on the outside of coffee, I may remark in some detail upon certain branching networks of delicate filaments, varying in quantity, modes of increase, and other characters. These are found chiefly on the under-side of green leaves in the moister weather, but also appear on the upper surfaces and on the branches, and, less abundantly, in dry weather. Their detection and comparison are easy, if the leaf be dipped whole in some weak colouring solution (iodine, magenta, &c.), which is absorbed by the filaments, but not by the epidermis of the leaf; on stripping off the latter, the microscope reveals the filaments as coloured networks on a colourless field. Prolonged study of these structures over all the coffee districts enable

me to state certain facts about them, which have compelled an entire reconsideration of the subject.

¶ 5. An examination of the drawings and notes made from the commencement of my work in February last, convinces me that there are four different kinds of these filaments; their distinction from one another depends on their modes of branching and jointing, their diameters and contents, the characters of the spores to which they are traced, and certain other peculiarities. It would be of no advantage to state these differences in detail without the aid of drawings; but as it is important clearly to apprehend the possible bearings of these structures on "leaf-disease," it is my duty to shew how far and with what results they have been traced.

They all arise from spores which, in shape, size, colour, and other peculiarities present no resemblance to the spores now known to belong to *Hemileia vastatrix*. Three (of the four) are easily grown in artificial solution ... in their modes of reproduction ... Province not to admit into their store-houses, at any price, inferior ... general characters of growth, present ... quality ... of relation to *Hemileia*. Even in cases where ... such blocks up a stomate, I can detect no junction with the ... mycelium of *Hemileia*. Neither have I succeeded in establishing ... relation between the prevalence of these filaments and ... of "rust" patches (c.f. App., A, and C) I am therefore of opinion that they have no genetic connection with the fungus in question.

The one filament of which exception is made above however, has hitherto given much trouble. I have not yet succeeded in making it bear fruit and have with great difficulty got it to grow at all in solution. It arises from an oval septate spore many times smaller than a spore of *Hemileia*, and is usually tinged with olive when old it produces branches pretty regularly at right angles, from which short branchlets may arise and block up stomata in the neighbourhood. I have not traced any connection between these branchlets and the internal mycelium of *Hemileia*.

¶ 7. The nature of my work prevents the drawing of any conclusions except from observed facts, hence I am unsatisfied as to the relations of this filament until its fructification is discovered. Thus much, however, appears certain; the spore from which it arises has nothing to do directly with the papillate spores of *Hemileia vastatrix*.

The action of reagents upon these filaments is simple enough they are, destroyed by weak acids and alkalies, solutions of carbolic acid, sulphurous acid (as evolved by the inter-action of sulphur and lime in presence of moist air), &c.

Sec. IV.—The Papillate Spores (Uredo spores).

In paragraph 7 of my last report it was stated that attempts to directly infect coffee plants with leaf-disease had failed: I have since been more fortunate, and after some doubtful trials have obtained a result in most respects satisfactory. I will premise by describing what occurs in experiments.

¶ 8. I have already (preliminary Report, §. 3) described the formation of germinal tubes by the orange-coloured particles of "rust," and used this fact as the basis for my statement that *each grain of the "rust" is a true spore (Uredo spore)*, and I further stated that the contents of the spore pass along the tube and fill a swelling (simple or branched) formed on the tube. The reason why these germinal tubes have not been hitherto described, appears to be due to the extreme transparency of the empty portions, and to the fact that they grow somewhat rapidly and apparently, especially at night.

Numerous observations of these phenomena of germination have obtained more information. On the estates I find the yellow spores germinating in the water attached to the leaves—dew, rain, &c. This is no more than should be expected, seeing one obtains such excellent results on glass slides and it also follows that they can germinate on the fallen leaves, &c., as I have actually observed.

¶ 9. But there are some peculiarities about these germinal tubes on the living coffee leaf. They appear to form very quickly, and are shorter and less branched than those obtained on glass slides. Very commonly they do not branch at all. They have nothing to do with the much finer and complex web of filaments commonly found on the leaf, as already described.

Very generally, especially on arriving at the orifice of a stomate, the end of the tube dilates into a swelling, usually simple, and the contents of the germinal tube pass into this, as already seen in glass-slide experiments. Sometimes, however, I find no such dilation, but the tube appears simply to empty its frothy granular contents (protoplasm) on to the leaf surface: similar masses which I have found before on leaves and slides may have this origin.

¶ 10. Experiments made from time to time throw still more light upon these facts. On growing these germinal tubes from the orange spores placed in various nutritive fluids other than pure water, certain differences of behaviour may be thus summed up: so far as I have proceeded a longer more branched and delicate tube appears to be formed in watery solutions containing traces of sugar, or the ashes of coffee, tobacco grass, &c., than in stronger and more complex solutions such as Pasteur's fluid,* sugar and minerals, &c., &c. The shorter tubes sometimes burst and emit their contents as clouds of granular matter on the slide. In some cases the spore emits such a mass without forming a tube. In all sowings a large proportion of the spores become empty without my being able to trace the fate of their contents.

¶ 11. Supplementary to these facts are a number obtained by sowing yellow spores on the leaves of young coffee plants grown in pots and kept as clean as possible. The spores were taken from vigorous, rapidly-formed spots of "rust" and placed in drops of pure water on the lower surface of the leaves chosen; these were young, and as vigorous and healthy-looking as I could get. After certain intervals, I took a small sample of the mass of spores sown, and examined with the microscope: on finding that the spores had germinated and thrown out tubes freely, I cut slices from the leaf substance over which the sowing was made, and so observed the changes in the interior. Similar observations have been made on clean quickly-grown shoots, cut off and placed in pure water under glass.

In most cases I find germination vigorously going on after 24 hours, provided the conditions of moisture are kept up—the drying up of the drop of water in which the spores are sown must be prevented by damp cells, or slowly dropping water from a siphon. Not all, but a (variable) number of the spores germinate thus readily, and at the completion of the process the surface of the leaf is found strewn with empty, papillate, spores, less remains of the spores and a number of greyish frothy masses of protoplasm, while here and there are remains of germinal tubes so transparent as to be hardly distinguishable. Over some, often many orifices of stomates occur the swellings before spoken of they have the appearance of bladder-like vesicles, often wrinkled, and with remains of germinal tubes attached. In early stages the germinal tube may be traced from the bladder-like swelling to the ... empty papillate spore-remnant, looking as if twisted ... the contraction of its delicate walls.

¶ 12. ... Sections of the leaf vertical to the surface not only confirm what has been described as seen from above, but also shew that the contents of the ... and tube pass into the swollen vesicle, and thence, after a short ... are to be recognised as a greyish ... irregular mass from which the coral-like mycelium ... Some ... details ... which require still further ... one point of importance ... which do not thus penetrate the stoma ...

¶ 13. I will now give in some detail an account of an experiment upon which the above facts bear directly. On the evening of September 11th, ... placed in a Wardian case a well-grown plant of *Coffea arabica* in its ... it bore ... pairs of fine dark green, clean-looking leaves. Every precaution was taken to ensure the absence of fungus spores from the case, soil, and plant and as always, the only water used was previously boiled and filtered. On the under side of one of the ... most young leaves I made a small sowing of yellow spores ("rust") taken fresh from a new disease patch, adding one drop of pure water; a small glass cell was then placed over the sowing, and gently held in place by a brass clip. The glass-roof of the Wardian case was then closed tight, the whole stood in a well lighted room, of which the average temperature was 78° F.

On September 13th, early in the morning, an examination of a small mass of the sown spores taken on the point of a needle showed that the spores had vigorously germinated and thrown out tubes on the ... surface of the leaf in all directions.

By September 30th most of the spores had germinated, though some still remained apparently unaltered, many appeared to have lost their contents without developing tubes. Among the *débris* of empty cases were several other fungal filaments, apparently vegetating on the mass of remains. The weather had been dry for some days and the interior of the Wardian case was somewhat dry, but the plant showed no signs of drooping. The most careful scrutiny failed to discover any external appearance of disease, and on holding up to the light no "pin-spot" or other sign could be detected.

On October 16th, however, a pale yellow spot of some magnitude was observed close to the area on which the sowing of yellow spores had been made five weeks previously, and in the centre of this a few rosettes of yellow spores were making their appearance. The plant was somewhat drooping from hot dry weather.

On October 19th a well developed patch of "rust" was evident, and already the centre had become tinged with brown.

On November 1st the spot was quite brown, and very few spores (orange rust) were to be seen. The remainder of the leaf, and all the other leaves showed no external signs of leaf disease, but were still of a bright green colour and to all appearance vigorous.*

¶ 14. This experiment is selected as being peculiar in several respects. In the first place (assuming total absence of spores at the commencement) the yellow spores were confined to a small area of the leaf. Secondly, no motion caused by wind or rain could have brought yellow spores. And yet lastly, the disease patch, when it did come was developed on the particular area selected—and this area was *on a very young leaf*. There are difficulties, and great ones, in dealing with objects as minute as these, but all the facts are in accordance with the view that in this experiment I *propagated the disease by means of the yellow spores directly*. If the disease spot had arisen from spores blown by the wind or otherwise conveyed on to the plant, it is difficult to explain why it arose on the particular part selected of a young topmost leaf, and nowhere else; for it will be noted that the disease spot, as usually found, occurs first on the older lower leaves. We must either suppose the apparently improbable falling of some spore during an incautious exposure on this very spot selected, or accept the view taken above—a view which is intelligible in the light of the other facts given (c.f. App. B).

Sec. V.—On the action of the Fungus upon the Cells of the Coffee Leaf.

In this connection I propose to consider the facts at present discovered, which throw light upon the phenomena of growth and increase of the "coral-like mycelium" in the well-known yellow diseased-spots: I have also much to say respecting the smaller so-called pin-spot but this will be more conveniently deferred for the present.

¶ 15. On cutting sufficiently thin sections of somewhat advanced disease patches in which the internal coral-like mycelium is vigorously developed, I have discovered certain organs by means of which the contents of the cells of the coffee leaf become transferred to those of the fungus. Such tapping or exhausting organs (*Haustoria*) are formed on a common plan. Within the cavity of a cell of the leaf is a minute pear-shaped or subglobular body, connected by a delicate tube *which passes through the wall of the cell* into a branch of the mycelium of the fungus: according to circumstances and the age of the various parts, this structure is hollow or solid. When fully developed; the intra-cellular globular portion is hollow and contains a few bright granules, the tubular neck long, and the piece of mycelium where they join closely applied to the outer wall of the cell: all these parts are colourless.

Now it is possible to demonstrate that as this exhausting organ increases in size and age, the contents of the leaf-cell in which it occurs gradually diminish in quantity—that, whereas the leaf-cell at first presented orderly arrangements of fluid and solid, coloured and hyaline parts, each with its functions for the carrying on of work and life, we at length find either an empty shell or a mere mass of brown vegetable matter.

In some cases I find one of these organs in a cell, at other times two or even three; and in a well-developed specimen almost every cell has its walls pierced by them.

¶ 16. Putting the above facts together, they appear not only to confirm the statement made in my last report (§ 3), but to shew the *modus operandi*, by which "the tubular branched mycelium of the fungus has been feeding upon the contents of the leaf-cells," as there stated. Having thus pro-

* A complex solution of tartrates, phosphates, &c., with sugar and ammonia, well-known as very nutritious to ordinary fungi.

* Up to December 1st no other rust patch appeared on this plant.

vided itself with food robbed from the plant, the mycelium at length grows rapidly underneath the stomata and forms peculiar compact masses which grow together through the orifices: from such a mass the orange-coloured spores are produced by successive budding in great quantities forming the main mass of rust so easily dispersed.

In this manner the leaf becomes rapidly exhausted of its cell-contents and the beneficial effect it exercised upon the plant as an elaborating and producing agent is materially lessened; not only is it robbed of much material, but its life is shortened in many cases, and the double work thrown upon it (so to speak) has to be accomplished in a shorter time. But the damage done to the leaf cells, and therefore to the leaf as a whole does not end with the mere removal of matter: the manner in which functional processes depend upon one another has to be taken into consideration also, and great injury must result from so profound a disturbance of the nutritive elements in the plant as has been indicated above.

¶ 17. In tracing the action of *Hemileia* on the leaf, and the results of premature destruction brought about by it, it cannot be too strongly urged that the leaves of the plant are the organs in which are prepared those materials necessary for the production of fruit and fruit-bearing parts of the plant. If we can show that of two sets of leaves otherwise equal, one set contains more of these materials than another, we are justified in pronouncing the former set to be more useful to the plant as cultivated.

The materials in question are chiefly carbohydrates and nitrogenous matters and the former (substances allied to starch and sugar) are especially dependent upon healthy leaf action for their formation and proper distribution.

Some information on this head may be gained by examining the results given by Mr. Hughes in a report to the Planters' Association (c.f. App. D.). According to his analysis, the solid matter in diseased leaves is sometimes much less by weight than that in healthy ones, if compared under similar conditions; the solid constituents of the diseased leaves were found to be different in proportions, and probably therefore in arrangement.

Now it is easy to shew that the above conclusions, arrived at independently, are in accordance with my own microscopic analysis. If the contents of the leaf-cells pass into the tubes of the fungus, and thence, undergoing change meanwhile, into the spores which are shed in such profusion, and if those substances also are used in building up the structure of the fungus, we have no difficulty in understanding the changes in quantity and proportion of the constituents. The fungus is composed of nitrogenous and carbonaceous matters similar to those of the leaf-cells; it absorbs such material from the leaf cells, and it throws off large quantities in the numerous spores so profusely shed at intervals; unless, therefore the leaf cells can supply both this drain on their contents and also the natural demands of the plant on their products, it is clear that either the fungus or the coffee tree must suffer, if only from want of nutrition.

Another point of interest is that certain easily decomposable carbonaceous materials in the healthy leaf have been found to suffer a large decrease in diseased leaves, while a considerable increment of another carbonaceous substance (cellulose) was found to occur in the latter, as had also to be of nitrogenous matters. This is quite in agreement with the fact, that the mycelium and spores of the fungus have their walls composed of such a carbohydrate, and contain such nitrogenous matters as have increased; if the leaves examined contained a large amount of mycelium, &c., we should expect just such an increase of these materials.

There are many and great difficulties in trying to explain the detailed differences of analysis, but I feel justified in concluding that the above facts, are all in agreement and tend to the same conclusion.

Sec. VI.—The Fall of Leaves.

The question how far this unseen damage to the leaf cells becomes visible to the unaided eye, may well be raised. It is the almost universal opinion of planters that the fall of leaf is now much greater and more frequent than formerly, and is directly due to leaf-disease (c.f. App. E. F. and G.).

¶ 18. I have had occasion to notice and compare several cases of leaf showers, and, so far, they appear to vary in several respects. In some cases a large and sudden fall of leaves has occurred over considerable areas of green coffee, on reaching the ground the leaves appear dark green on the whole, but examination shews a mottled appearance such as is so common before the "rust patches" appear on the outside. In many cases I can detect the fungus mycelium inside, and consider its action the main cause of the fall, isolated trees, here and there, being in great part exempt from both disease patches and leaf-fall. In other cases, where the brilliant orange rust comes out suddenly on the still attached leaves, the connection between the "virulence" of the disease and the rapid and large leaf-fall cannot escape attention; in a short time the whole branch may be almost denuded of leaves, from below upwards.

¶ 19. But in the more usual case, where the fall of leaf is distributed over a long period, there can be no doubt that other factors complicate the question: though the leaf-fall may be very large, and is always in the main from below upwards, it is very improbable that "leaf-disease" is the sole cause, and others can readily be detected. It is generally admitted that a large proportion of the leaves of coffee always turn yellow during the last stages of crop, and at length fall in showers—the autumn of the coffee in effect; now it is a common occurrence to find a tree with much crop and few leaves standing next to one with plenty of leaves and no crop or very little. In such a case the fall of leaf, however much hurried by the action of the fungus, is partly due to the same causes as are always recognised in the maturity and decay of leaves; the tree with no crop preserves its leaves longer, and this not because it has no leaf-disease, but because the sum total of drains upon the contents of the leaves is less than in the above-cited example. But in many other circumstances of the many under which coffee is grown, I find other causes at work also. Wind not only aids in detaching weak leaves, but, by drying and stunting them it helps to bring about the weakened condition—the smaller deformed leaf does less work for shorter periods. Damp soil, drought, &c., act in various ways to the same end.

Sec. VII. The effect of Leaf-fall on the Branches, &c.

¶ 20. The "dying back" of branches, &c., is a feature of diseased coffee much insisted upon by the planters, and I have devoted considerable attention to it during my journeys. A good example was afforded by the Jamaica coffee plants referred to in my preliminary report (§ 1); the majority of these became so badly affected with disease that they succumbed. The lower leaves rapidly dropped as the "rust-spots" turned brown: progressing upwards, the fall of destroyed leaves occurred faster than the formation of new ones by the apical bud, until at last only one pair of leaves remained, even these being diseased. This imperfect pair of leaves not being sufficient to keep up any large flow of sap in the single thin stem they shrivelled up, together with the upper part of the stem, turning brown and "dying back." There are several peculiarities here; as always even when rapidly progressing, the advance of the disease-wave is forward—the leaves most affected are almost invariably the oldest and lowest, and the fall of leaf occurs at the lowest parts first. It is commonly complained of that "young plants suffer more from the disease than older and well-established trees." If by this is meant that they shew more quickly and obviously the extent to which such damage as the above is done, it appears to be generally true; but I find no evidence to shew that they are in any way more susceptible to the attacks of *Hemileia* than well-established coffee. It is, however, true that taller trees can easily shed spores from their greater height on to young plants in the neighbourhood, and though the surface of the latter is less, it will probably be the more fully occupied: the period of inter cellular life enjoyed by the fungus may also be lessened by the total food supply being less, and hence a rapid outcome of yellow rust gives the impression of greater virulence on a small plant. On a larger plant though the fall of diseased leaves is quite as great on each twig, it is not so soon remarked (c.f. App. G.)

But when the fall of leaf reaches a limit and the young plant has but one apical bud, a rapid drying up of sap in the upper parts may be fatal; whereas when similar denudation occurs to the various lateral branches of a larger and well-established tree, the total flow of sap up to the whole mass of terminal buds may be sufficient to carry on the work of leaf-formation longer, and a drying up and consequent dying back be delayed or even prevented.

¶ 21. The importance of the leaves to the branches and stem which support them cannot be too strongly insisted upon in this connection. When crop is on the trees, the groups of fruit situated in the axils of the leaves are also to be looked upon as deriving nourishment from the latter through the branch, and when leaf-disease is bad—as is commonly the case during the period that crop is maturing—some explanation is possible according to the above statements, for the leafless and shrivelled condition of many branches. Exhausted on the one hand by crop, and on the other by fungus, no wonder the leaves become rapidly poor in food materials, turn yellow, and fall all along the branch up to the terminal bud; whatever sap then flows upwards will be used by the crop, and never reach the bud, which consequently dies. Hence the branch dies back in its upper part, and a greater or less quantity of fruit also; while in other cases the starved crop is "light."

¶ 22. As might be expected, there are several sources of complication. A simple case is when a rapid fall of leaf occurs during the middle stages of crop from coffee on dry soil; the flow of sap is here not vigorous, and a dry twig is soon all that remains on the end of the branch. In deep soil, or under more favourable conditions of shelter, &c., an actual drying up of the end twig may not take place, but the want of leaves diminishes the amount of woody fibre formed, and a result is "bad wood," nevertheless I often find the crop mature, apparently from the flow of sap in the tree generally being vigorous.

Another case may be selected from damp districts, where the leaves often fall in immense quantities during the prevalence of the fungus "rust." Here the denuded branches have no means of ridding themselves of surplus water, and a rotting back of the wood may take place: such cases may be attended by scorching in the midday sun, especially if the wind is dry.

It will thus be seen that numerous evils arise directly from a large fall of leaf, and that the details may be complicated in several ways. Wind, especially in high situations where the soil is dry and poor, may be even more disastrous than ordinary drought; not only does it dry up the parts but aids in the more effectual stripping of the branches by tearing off weakened leaves.

¶ 23. Into the outer dying portions of such branches as I have referred to a fungal filament is commonly found penetrating the rotting tissue; this fungus is one of a group which can only feed on dead or dying matter, and is incapable of injuring the healthy branch. Its "fructification" is soon accomplished as the very minute black dots so often shewn to me on estates: as the branch becomes black and shrivelled, they are not easily seen, but on rapidly dried "bad wood" they shew up well on the greyish ground. This fungus is the same as the one producing the black dots so numerous on old, dead, or dying disease patches on the upper surface of leaves: in the latter case they penetrate the brown rotting mass brought about by the ravages of *Hemileia*, but have, of course, no connection with it.

¶ 24. But there are still other secondary phenomena dependent on the fall of leaf: in young coffee plants it may happen that the leaves fall during a hot dry period, and a drying up and final destruction of axillary buds be produced. This occurs sometimes with one-year-old plants early deprived of their leaves—protecting as well as sustaining organs—and a woful want of secondaries may result: such a state of things means loss of time as well as strength until equivalents are produced to say nothing of damage to the shape of the young tree. A similar result may be brought about by damp rotting off the injured buds.

¶ 25. Yet other evils, especially on damp subsoils, arise from those enumerated: where the loss of leaf becomes so great that transpiration is not sufficient to prevent a general dampness and coldness of the plant, the roots and lower part of the stem may rot to a greater or less extent. I have had occasion more than once to examine such trees, and can refer the evil to no other causes. Nevertheless cases occur where the age and treatment of the trees, and a general history of the estate point to other causes at work in no way connected with leaf disease. I find great difficulty in getting the necessary information in some of these cases, not from any fault of the planters at present on the estates, but on account of the age of the coffee and the many changes of circumstances it has undergone. There can be no doubt, however, that heavy crops in the past, the effects of wash, ill chosen manuring or even none at all, as well as the great age of the trees, have had some effect on the present state of affairs. It is no valid argument to speak of old coffee now doing well, unless it is at the same time shewn that such coffee has undergone as great hardships and is at present no more favoured than the other. At the same time the marvellous power to reinforce itself that the coffee tree exhibits, may justly be insisted upon where other things warrant it, and it seems impossible to doubt that the mitigation of leaf-disease would be followed by a rapid improvement in the crop-producing capacity of coffee.

The fact must not be overlooked—and this point is of importance with respect to heavy manuring—that the continual renewal of leaf calls forth great energy on the part of the tree, and it no doubt follows as a direct consequence of this that the crop-producing capabilities of the tree are for the time lessened.

[Here follow Mr. Ward's summary and appendix which will be given in our next number.]

SELECTIONS.

MOVEMENTS OF PLANTS.

MOST people will no doubt be surprised to learn that plants have any power of movement at all We have always been taught that one great distinction between plants and animals is that the latter have the power of movement, while the former have not But there are movements and movements; and the kind of movement in which plants are deficient as contrasted with animals, is that of locomotion So far as observation has hitherto gone, plants have no power of changing their place by their own impulse. But with this exception, the readers of this, the latest work from the fertile brain of our greatest biologist, will learn that every part and every organ of a growing plant is in a state of ceaseless motion. All Mr Darwin's works have a family likeness Starting with some suggestive fact or idea, he records a long series of experiments conducted with the greatest precaution and delicacy, and from those he deduces, with the greatest caution and reserve, the most obvious conclusions to which they point Such also is the method of the work before us One or two German botanists have noticed that certain parts of plants are constantly moving, in a special kind of orbit to which they have given the name of circular nutation. The point of the leaf of a growing plant, for example, describes during the twenty-four hours a small orbit, more or less elliptical, and in the case of climbing plants creeping round their supports, this course is approximately circular Mr Darwin and his son Francis, who has himself already done some remarkable work in botanical research, have for some time been conducting a long series of experiments to discover what is the real nature of this curious elliptical motion, to which they give the name of circumnutation, and to what extent it prevails among the various classes of plants, and the various organs by which plants carry on their functions The conclusions which they have been able to reach are very remarkable The motion of the root downwards in the ground, the motion of the stem upwards to and in the air, the motions of the leaves from day to day, the peculiar nightly set of leaves known as sleep, the tendency of leaves to seek the light the action of gravitation, and so on, are all modifications of this one movement of circumnutation, adaptations of what seems a primitive innate motion, to suit a great variety of circumstances. The tiny rootlet or radicle emerging from the seed, gyrates as far as it can in its earthy home, ever tending downwards, but seeking out invariably the path of least resistance, and the soil from which it can extract the greatest moisture and nourishment. The embryo leaf-bearing stem, in the same way, oscillates upwards to the light, and when it spreads out its two first leaflets, these also begin their career of oscillation in the open air And so with every leaf and petiole and other part as it comes forth, until every detail of the growing plant is in a state of constant elliptical motion Here is Mr. Darwin's graphic account of the phenomenon —

"Our seedling now throws up a stem, bearing leaves and often branches, all of which, when young, are constantly circumnutating If we look for instance at a great acacia tree, we may feel assured that every one of the innumerable growing shoots is constantly describing small ellipses, as is each petiole, sub-petiole, and leaflet. The latter, as well as ordinary leaves, generally move up and down in nearly the same vertical plane, so that they describe very narrow ellipses The flower peduncles are likewise continually circumnutating If we could look beneath the ground, and our eyes had the power of a microscope, we should see the tip of each rootlet endeavouring to sweep small ellipses or circles as far as the pressure of the surrounding earth permitted All this astonishing amount of movement has been going on year after year, since the time when, as a seedling, the tree first emerged from the ground"

Mr. Darwin's experiments were made on plants belonging to the most diversified classes, so that he is justified in concluding that the varied movements he noticed in these are common to nearly all plants. Among the special kinds of movements investigated by him are those to which plants are subject under the influence of light and those which are peculiar to the leaves of certain plants on the withdrawal of light and the approach of night. The tendency of plants to seek the stronger light is well-known, and Mr Darwin made many experiments in reference to this characteristic. Even the very smallest amount of light has an influence on most plants, though in many experiments it was found that after bending towards a strong light, a feebler light failed to unbend them in an opposite direction In the case of seedling plants such as the bean, say—Mr. Darwin found that the sensitiveness to light dwells in the tip of the stem and that if that were cut off from the source of light the lower part of the stem refused to expand to its influence. In the root, also, it is the tips of the radicle and the subsidiary roots that are the sensitive "feelers, so to speak, and if these tips are cut off, the remaining parts are practically motionless Indeed so important is the function of the tip of the radicle, and so sensitive is it to the slightest touch or pressure, and so marked is the influence it transmits to the rest of the radicle, that Mr. Darwin likens it to the brain of the lower forms of animal life With regard to the sleep of plants, Mr Darwin records a long series of observations in the volume before us. The conclusion he comes to is that it is not the mere absence of light that leads to these leaves assuming a vertical position at night either by rising up or drooping down, "The absence of light or its absence cannot be supposed to be the direct cause of the movements, for these are wonderfully diversified even with the leaflets of the same leaf although all have, of course, been similarly exposed The movements depend on innate causes and are of an adaptive nature The alternatives of light and darkness merely give notice to the leaves that the period has arrived for them to move in a certain manner. We may infer from the fact of several plants not sleeping unless they have been well illuminated during the day, that it is not the actual decrease of light in the evening, but the contrast between the amount at this hour, and during the early part of the day, which excites the leaves to modify their ordinary mode of circumnutation" The object gained by all the varied positions assumed at night is Mr Darwin tells us the protection of the upper surfaces of the leaves from radiation, often combined with the mutual protection of the several parts by their close approximation The so called diurnal sleep of some plants, he finds, is merely a twisting of the leaves to avoid receiving the glare and heat of the sun on the upper surfaces, to which it would be injurious

But whatever may be the object or the special nature of the various motions to which the different parts of the plants are subject, Mr Darwin comes to the conclusion from his long and varied series of experiments, that they are all adaptations to suit special circumstances of the one primitive motion which he has called circumnutation—one more proof of the great law of natural selection and the tendency of all living things to adapt themselves to their surroundings It would take much more space than we can spare to give anything like an adequate idea of the varied subjects treated of under this apparently simple title of this work Mr Darwin here shows no falling off in that marvellous power of observation and induction which has marked all his previous works, and we hope he will still be long spared to exercise a power which has led to a revolution in the methods of science and changed the whole aspect of modern thought and research —*St. James's Gazette*

MR. THOMAS BOLAS, ON INDIA-RUBBER.

INDIA-RUBBER or caoutchouc possesses properties so widely different from those of most other substances, that it became an object of very great interest as soon as it made its appearance in the civilised world and its industrial importance has rapidly increased as the knowledge of its remarkable characters, and manifold applicability has become more extended At the present time, caoutchouc holds such an important position with regard to the economy of modern arts manufactures that were it suddenly to be withdrawn from circulation many minor industries would in consequence cease to exist, while numerous large and important branches of handicraft would languish until arrangements could be made to adapt their operations to the altered circumstances It is, however, during the last forty years that India-rubber has enjoyed its greatest triumph as an industrial agent, that is to say since the art of vulcanisation was discovered and perfected by the labours of Charles Goodyear, Thomas Hancock, and others

The earliest rumour of the existence of caoutchouc reached Europe 500 years ago, the first visit of Columbus to Hayti having brought to light the fact that the natives of this island were in the habit of making playing balls of an elastic gum. Nothing more appears to have been heard of India rubber until Torquemada, rather over 200 years ago, described the Mexican Indians as not only making playing balls of India-rubber, but also as fabricating helmets, shoes, waterproof fabrics, and other articles of elastic gum. This writer gives some details as to the collection of the juice and the making of various articles from it, thus giving us the first view of the India-rubber manufacture as a branch of industry. We do not hear however of samples of India-rubber reaching Europe until long after this and little more appears to have been learned regarding the substance until the celebrated French naturalist, La Condamine, made a communication to the Academy of Sciences at Paris concerning caoutchouc, he having had ample opportunities of studying the subject in Para In the memoir in question, La Condamine gives very detailed particulars regarding the Para India-rubber tree, the collection and treatment of the juice, and the methods made use of by the natives for the production of various articles of caoutchouc. He tells us that the substance in question was used for making torches, these being only an inch and a half in diameter by two feet long, and yet burning for 12 hours Again we hear of the use of India rubber for the making of playing balls and it appears, that the natives were in the habit of using enemas or injection bottles made of caoutchouc

Soon after La Condamine's communication to the Academy of Sciences, samples of India-rubber frequently reached Europe, and scientific men began to make investigations regarding this remarkable body. Between 1750 and 1770, we find Fresneau and Macquer studying the subject, and the last-named investigator made tubes and other articles of caoutchouc by dissolving it in ether and coating moulds with the solution, so that a solid skin of caoutchouc should remain adherent to the mould, on the evaporation of the solvent.

From this time until the end of the eighteenth century, the India-rubber industry may be considered to have been undergoing its period of gestation, and to have been born with the dawn of the present century Among the first of the important patents regarding the utilisation of the caoutchouc, is that granted in 1823 to Charles Macintosh, for dissolving the substance in coal oil or coal naptha, and the use of this solution as a waterproofing agent.

About the same time, elastic webbing was first made with threads, cut from the raw-rubber and other minor applications of caoutchouc to the industrial arts were adopted from time to time, until the great discovery of vulcanisation inaugurated a new epoch in this branch of industry rendering it possible to so far alter caoutchouc, as to make it capable of resisting, to a great extent, the action of the heat on the one hand, and cold on the other

The milky sap of many plants contain caoutchouc, suspended in the form of minute transparent globules, these being frequently as small as 1-20,000 to 1-50,000 of an inch in diameter; but comparatively few plants contain sufficient caoutchouc to render them important sources of this body.

The trees which yield the largest supply of the best quality of caoutchouc consist of various species of Hevea which flourish in northern districts of South America especially in the province of Para, some portions of the banks of the Amazon being crowded to an extraordinary extent with Heveas. The abundance of the India rubber trees in Para may be judged of by the fact that this province alone exported 7,840 tons of caoutchouc in the year 1876; more than half of this being sent to Liverpool.

Among the Heveas most productive of caoutchouc may be mentioned the *Hevea brasiliensis*, which flourishes in Para, and yields some of the finest caoutchouc, and often attains a height of 60 to 70 feet, with a diameter of nearly three feet, the *Hevea guianensis*, a similarly magnificent tree, is likewise abundantly productive of caoutchouc, and the *Hevea spruceana*, a smaller tree, which grows almost exclusively in the province of Para.

The operation of collecting the juice is as follows:—A series of cuts being made through the bark of the tree, either shells or clay vessels are attached to receive the exuding milky sap, and when sufficient of this has been collected, the operation of drying it is performed in the following manner. A kind of wooden—bat thinly covered over with clay, is dipped into a pail filled with the juice, and the bat, thus coated is held over a fire, fed with certain wild nuts which, in burning, give off abundance of aromatic smoke. As soon as the first layer of juice has become indurated the bat is again dipped, and the drying operation is repeated, layer after layer being thus dried on the bat, until a thickness of nearly an inch is attained. A knife-cut is now made in the bottle or biscuit of caoutchouc, so that it can be removed from the wooden bat, and exposed to the air to become still further indurated. Para caoutchouc, prepared in this manner has a fragrant aromatic odour.

The residues of juice left in the various vessels employed, the scrapings of the incisions together with other materials which the ingenious native thinks he can shuffle off on the unsuspecting merchant as caoutchouc are made into balls and sold as "negro head." The negro head rubber is frequently made into crude representations of animals, and several specimens of this kind of native art have reached this country.

The milky juice of the Para rubber trees, has approximately the following composition:—

Caoutchouc	32
Albuminous, extractive, and saline matters	12
Water	56
	100

As a rubber producing tree *Ficus elastica* stands next in importance to the Heveas. The *Ficus elastica* tree grows abundantly in India and the East Indian Islands—one district in Assam, thirty miles long by eight miles wide being said to contain 43,000 trees, many of them attaining a height of a hundred feet. This tree also grows freely in Madagascar, and it is well known to us as a green house plant.

The juice of the *Ficus elastica* contains notably less caoutchouc than that of the American trees, the proportion very often falling as low as ten per cent of the juice.

A vine-like plant, the *Urceola elastica*, which grows abundantly in Madagascar, Borneo, Singapore, Sumatra, Penang, and other places, yields a considerable amount of caoutchouc of very good quality. Africa yields a considerable quantity of caoutchouc generally soft and of inferior quality. It is believed to be yielded by various species of *Landolphia*, *Ficus*, and *Tabernæmontana*.

The commercial value of the various qualities of rubber may be estimated, to a certain extent by calculating the loss which the samples undergo during the operation of washing, and also by noticing how far the various samples are softened by a long continued gentle heat.

Caoutchouc is nearly colourless and when in thin leaves, tolerably transparent. Like very many other substances, it contains nothing but carbon and hydrogen, but its properties differ very widely from those of other hydro carbons almost identical in composition. It has been found to contain in one hundred parts, 12.5 of hydrogen and 87.5 of carbon. Caoutchouc, as might be supposed, burns very readily, and leaves no residue. It is soft and very imperfectly elastic, in the true sense of the term, that is to say it does not return to its old dimensions after having been considerably stretched.

As regards the stretching of India-rubber, there is a point at which it requires a greatly increased force to stretch it, and at this point it seems to become fibrous in texture. India-rubber has valuable electrical properties, it being an admirable insulator, and having a great tendency to become electric by friction.

Freshly cut surfaces of India-rubber cohere very strongly when brought into contact.

Either French chalk or soapy water is of constant use in the rubber factories, to prevent the adhesion of new surfaces of caoutchouc to other substances or to each other.

BAT'S GUANO.

MERELY to adopt any improvement in agriculture may be considered indicative of a fair amount of intelligence, for the rustic mind is, all the world over, averse to novelties or improvements; and the mind of the Indian rustic is, to say the very least, no exception to the rule. The ryots of Chennur, therefore, on the banks of the Penna river, a little to the north of Cuddapah, deserve some credit for adopting the use of bat manure, which is said to have doubled the produce of their paddy-fields. But from a paper contributed in 1878, by Dr. Voelcker, Consulting Chemist to the Royal Agricultural Society of England, to the journal of that Society,—for a perusal of which we are indebted to the kindness of a gentleman whose attention was attracted by a letter we published last week,—we learn that "Bats' Guano" is found in Arkansas and Texas, in the south of Spain, in Jamaica, on several islands belonging to the group of the Bahamas, and on several East Indian Islands.

"Bats' guano consists of the more or less decomposed dung of bats, and of their dead bodies, mixed with variable proportions of earthy matter. It varies in colour from light brown to dark brown, and generally smells but faintly of ammonia. Some samples are light, powdery, dry, and full of fragments of the wings of insects; others are heavy, earthy in appearance, and quite void of smell."

"This fertilizer is found in caves inhabited by innumerable bats, attracted to the neighbourhood of caves by swarms of insects, which infest certain swampy districts in semi-tropical countries and which afford abundant food to the winged mammals. The most extensive accumulations of bats' guano appear to have been found in numerous rocky caves in Texas and Arkansas. Some of the caves yield comparatively little guano, others many hundreds of tons and from 15,000 to 20,000 tons are reported to have been taken from a single cave in Texas. The number of bats frequenting the caves amounts to millions, and when they issue forth, they darken the air as if a great volume of smoke were pouring out from the opening. Caves covering miles of ground and inhabited by innumerable bats, are also found in Arkansas, and there can be no doubt that the caves in Texas and Arkansas contain large stores of bats' dung of sufficiently good quality to be usefully employed for agricultural purposes."

The results of chemical analyses were very various—so various that we can neither quote nor summarize them. The quality of bat guano seems to depend partly on the kinds of insects that form the food of the bats, and partly on the character of the caves which they frequent. Caves with rocky sides and floors probably supply better guano than caves whose sides and floors are earthy. Whatever be the cause the character and marketable value of bats' guano are very variable. 'Bats' guano' includes manures, some of which contain as much as 10 per cent of ammonia, and others only 1 per cent and even less, and which differ in value from £3 per ton and even less, to £11 a ton and upwards. Some kinds that contain very little ammonia derive what value they possess from the proportion of phosphates that they contain.

Bat manure is found in Penang, and is there known by the name of "Type water." It is said to be adulterated by Chinese dealers; and the only specimen analysed by Dr Voelcker was very poor in ammonia, but rich in phosphates and salts of potash containing 33 per cent of phosphate of lime and 6 per cent of alkaline salts, including nearly $2\frac{1}{2}$ per cent of potash. Ceylon where, "including the frugiverous section, about sixteen species of bats have been identified, ought to contain abundance of bats' guano. Sir J. Emerson Tennent writes:—"The multitude of bats is one of the features of the evening landscape. They abound in every cave and subterranean passage, in the tunnels on the high ways, in the galleries of the fortifications in the roofs of the bungalows, and the ruins of every temple and building. At sunset they are seen issuing from their diurnal retreats to roam through the twilight in search of crepuscular insects, and as night approaches, and the lights in the rooms attract the night flying *lepidoptera*, the bats sweep round the dinner table, and carry off their tiny prey, within the glitter of the lamps."

The idea of bat farming was thrown out by our correspondent. The guano hitherto in use in agriculture is deposited by troglodyte or cave-dwelling bats, which are also insectivorous. The essentials to the culture of these creatures would be insects to eat and caves to dwell in, or instead of caves, tunnels would answer; but the locality chosen for them must abound in insects, such as humid or swampy tracts of land containing forest, or at least scrub or jungle trees. These abound on the Western Coast of India and may be found on the Coromandel coast. In the Western Coast, the need of any manure is hardly felt, for the soil is fertile, and fish manure is used. Yet the planters have introduced the use of bone manure, and this might be greatly extended by the distribution of a few bone-crushers over a country which trades so largely in skins. To return however, to our bats, if it be found that they have a taste for mosquitoes the culture of them must be interesting to others besides agriculturists. What insects there are in India must be eaten up by birds, and the deposits of these are washed away by the rains. Bats' caves would preserve the fertilizing matter for the husbandman. There is a class of bats known as flying foxes. Though their teeth and habits shew that they feed on insects, yet they are mainly frugiverous, and dwell in trees hanging from their branches. But it is doubtful whether their deposits can be of much value as manure. The culture of these creatures would not be difficult if it were worth attempting, and this could easily be ascertained by Mr Robertson and a chemical analyst.—*Madras Times.*

PERUVIAN GUANO STATISTICS.

IT is roughly estimated that the nitrate beds of Peru contain about 60 millions of tons. Those of Bolivia, thus far known, are, although large, inferior in extent to the neighbouring ones in Peru. In Northern Chili some 3,000 tons per annum are exported from deposits already reported. It is not improbable that extensive nitrate deposits may yet be found in Argentine Patagonia, able to compete with those of Peru. In 1878 the estimated tonnage of the southern deposits of guano was as follows:—

	Tons.
Huanillas	1,000,000
Point Lobos	200,000
Pabellon De Pica	350,000
Chipanabay	250,000
Add for the Lobos Islands	600,000
Total	2,400,000

Other deposits of great extent have been reported, but their cubic contents and market value are doubtful. The average annual consumption of Peruvian guano during the ten years from 1869 to 1878 inclusive, was about 345,000 tons. The consumption of nitrate by the North Atlantic nations is shown by the following table of Peruvian shipments:—

	Tons.		Tons.
1866	99,440	1873	284,715
1867	115,925	1874	255,783
1868	86,659	1875	326,869
1869	113,957	1876	320,491
1870	133,790	1877	213,940
1871	163,903	1878	250,000
1872	200,943		

—*South American Journal.*

ARTIFICIAL MANURES.

A GREAT deal of useful practical information has been written on this subject; also a lot of theoretical humbug, based on popular fallacies. In some of the communications I am sorry to notice an undercurrent of envy, or, at all events, ill feeling, towards scientific men, such as Dr. J. B. Lawes, Dr. A. P. Aitken, and Mr. Jamieson, all of whom have laboured earnestly to elucidate the question of the economical use of artificial manures—a question which I am sorry to say receives even yet too little attention from the agriculturist, take an average all over the country. I honestly believe that not less than one-third of all the artificial manures used are misapplied; and yet farmers are to be found who will write, speak, and sneer at those who are labouring hard to save their money.

The value of the results conducted by the scientific gentlemen I have just named can hardly be over-estimated, as forming a general guide to the economical use of artificial manures, but with variety of soils and climates, under different conditions of cropping and previous manuring, considerable variation both of quantity and proportion of constituents of an artificial manure are necessary to grow full crops, therefore the results of the experiments to which I have alluded are only applicable in their entirety to the immediate districts in which they have been carried out, or to similar soils under similar conditions, and are only useful otherwise in a general way as scientific facts.

Soils in an ordinary condition of fertility generally possess, to some extent, every plant food constituent necessary for the growth of the ordinary crops of the rotation. But some of the most necessary constituents may be present in very small proportion, whilst others may be there in superabundance; and as most practical farmers are, or ought to be, aware, the bulk of a crop does not depend on the presence in the soil of a single plant food constituent, but on all the necessary constituents being there in proper proportion. In fact whilst the bulk of a crop depends on all the essential ingredients being there in the right proportion, an excess of any one of them may, and very often does, prove injurious instead of beneficial to the plant. The manure applied, therefore ought to aim at supplying any deficiency of these constituents, and the one most suitable for doing so will most undoubtedly give the best and most economical results.

Analysis to certain extent may assist the farmer in forming an idea of the deficiencies of his soil, but cannot always be relied on as a correct guide, and may often be misleading, as it very frequently occurs that plant-food is present in considerable quantity in the soil, and yet not in a condition to be available for being absorbed by the plant. Thoroughly reliable results can only be had by practical test in the field, and as these only apply to soils under similar conditions, &c., as already stated, they should be repeated in every district.

In reference to the ground phosphate question, I can positively affirm, from personal experience in the field, that it is both a valuable and economical fertilizer for the turnip crop; this year having given better results than superphosphate on several farms in central Forfarshire. I will quote an example on one of the farms, with a light, sharp soil. Crop, yellow turnips, natural produce of the soil, 185 cwts per acre of bulbs; addition of 2½ cwt of finely ground tribasic phosphate produced 429 cwts at a cost of 19*s.* 6*d.* per acre. The further addition of 1 cwt of pure (kelp) sulphate of potash, at a cost of 10*s.*, further increased the production to 533 cwt per acre. The still further addition of 1 cwt sulph. of ammonia, at a cost of 19*s.* 6*d.* raised the produce to 680 cwt per acre. The total weight of the triple plot was 29 tons per acre of roots and 92 cwt per acre of shaws, at a total cost of 49*s.* an acre.

The corresponding plots treated with superphosphate (same weight of phosphate) gave, on an average of three plots, 68 cwt less of roots, and 16 cwt less of shaws, at an increased cost of 1*s.* an acre, being additional cost of super over the ground phosphates. On some of the other farms, where the soils were heavier, the results were more nearly equal.

I never had the opportunity of testing soluble against insoluble phosphates on heavy clays, but would readily believe from my experience on medium soils, that heavy clays would give much worse results with ground phosphates than medium soils, while light sharp soils would give much better results. I am far from saying that the saving to be effected by the use of ground over soluble phosphates is to be a panacea for the existing distress; but on soils suited for its use, it is likely to be a considerable saving in the manure bill, if ground down to an impalpable powder, which alone constitutes its principal value, its source being a very secondary consideration to its mechanical state of division.

Applying *rough ground* phosphates at the rate of 10, 15, or 20 cwts per acre, as some of your correspondents seem to imply they have done, and expect miraculous returns from the application, is simply absurd. As a matter of fact this rough mechanical state of division of insoluble manures generally receives far too little attention. I had this very clearly proved during the past season on one of the farms to which I have alluded. The tenant applied a well-balanced mixture of nitrogen, potash, and phosphates, at a cost of 63*s.* an acre. This manure, generally speaking, would have been said to have been in a fair state of division, but was very rough as compared with that used on the triple plots to which I have already referred.

The result was a crop no better than ground phosphate alone, and 6 or 7 tons worse than the triple plot, at a cost of 49*s* per acre. I ascribe the bad results mainly to bad state of division, and also to the combination of some of the manurial ingredients, the nitrogen in the one mixture being mainly from raw bone, while in the other it was a soluble salt. The potash was from kainit in the one, and from kelp sulphate in the other.

In reference to potash the results I have obtained from kelp or seaweed sulphate, as compared with muriates and chlorides, or mixtures of them, as are frequently found in foreign sulphates or refuse of factories. I find I have more profit to use the kelp sulphate in preference to the others, even with a difference in cost of 20 to 25 per cent. As may naturally be supposed, this difference in price is apt to entice dishonest vendors to offer the one for the other.

I can quite understand what your correspondent "S" wrote the other week in regard to [illegible] that should be much more largely used for the growth of turnips and potatoes.' I have frequently advocated this in your columns during the past few years. I do not mean to say that it will apply to every district, but I find in this district farmers are becoming gradually alive to its importance as a fertiliser for the crops, and last year there would be 20 tons used for 1 ton used five years ago; the increasing demand for this salt is the best evidence of the results produced by its use. I believe many districts do not require it, but that can easily be known by test in the field. Central Forfarshire is certainly not one of these, as potash in a soluble condition is present in a very small proportion in the natural composition of the soils.

Instead of each individual farmer giving his isolated experience of this manure or that manure, farmers ought to combine in each district, and conduct experiments with manures for their own guidance. I am quite convinced that much might be learned in regard to the economical use of manures by following out this system, and that reliable results might always be had on which the whole district might rely, by having several duplicates here and there over it.

The expense of conducting these experiments properly is very considerable, but unity is strength, and I am quite certain it would both repay labour and expense a hundred-fold. It would, to say the least of it, be more in unison with this age of progress than snarling and snapping at every one who has the moral courage to emerge from the old beaten track in the manuring of his crops.—THOMAS LAWSON in *N. B. Agriculturist*.

PLANTS AND FROSTY WEATHER.

SOME observations made at Giessen last winter by Herr Hoffmann throw light on the way in which plants are injured in time of hard frost. The great advantage of a hilly position was then apparent; the plants so situated took little or no harm, while quite near, in the valley, there was extensive injury. The injury, too, decreased in proportion to elevation above the valley. Some tender fruit trees placed in specially favourable circumstances on the low ground withstood the lowest temperature (23 deg. R.) Still more instructive was the fact that one and the same bush—*e.g.* of *buxus* or *thuja*—was killed in its foliage on the south side, while on the north side it remained green. The author infers that it is not a particular degree of cold (determinate for each plant species) that kills a plant, but the amount of quick thawing. This sudden variation of temperature was in the cases considered some degrees less for the plants in a high situation and for the shady sides of the half-killed shrubs. It is immaterial (Herr Hoffmann says) whether the thawing be caused by a warm wind and at once or daily repeated by the sun. On December 23 at Giessen, in the valley, the air temperature was raised (by a south-west storm with rain) from *minus* 17 deg. in the night, to *plus* 3 deg at mid-day. On the hills the thawing wind acted with the same high temperature, but the previous cold was less. The effect of thawing by the sun could be observed on pear trees in the middle of December, long before the thawing weather came, they were killed by the daily variation of temperature of over 20 deg from the night *minimum* to the day *maximum*. Herr Hoffmann also considers that when plants are thoroughly frozen the killing takes place as surely whether the temperature of the plant be raised—*e.g.*, 20 deg.—from *minus* 17 deg. to *plus* 3 deg, or from *minus* 10 deg. to *plus* 10 deg. With each degree of less variation the injury is proportionally less, and for each species the fatal amplitude of variation is special and determinate.

BULANDSHAHR FAIR—1881.

THE annual Government Horse Show and District Fair of Bulandshahr was held from the 22nd to the 26th February, under the management of the Collector, Mr. Growse. We take the following account of the fair from the *Pioneer*:—The fair is yearly increasing in importance, and the one just over was the most successful yet known. A considerably larger number of horses and mules were brought for exhibition than in the previous year, and being of good quality met with a ready sale at remunerative prices. The District Show, properly speaking, comprises an exhibition of cattle, agricultural produce and implements, and manufactures. The show of cattle was small, the wholesome rule having been enforced that prize winners of previous years should not again be allowed to compete. Some handsome bulls were exhibited and a few cows [illegible] buffaloes, sheep, goats, fowls, and pigeons. In produce there was the excellent white wheat of the Meerut division, oats (which are commonly grown in the same part of the country) pulses, fibers, dye-stuffs, and a good though rather short stapled cotton. Amongst the implements were several kinds of adapted ploughs exhibited by Mr. Martin, Mr. Crawley, Mr. Gavin Jones, and the Department of Agriculture, which also brought forward an adapted winnower, which should in time obtain a ready sale. An essay might be written on the comparative merits of the native and the adapted English ploughs, and of deep and shallow ploughing; but a stricter test and more searching examination is required than was here possible before any decided opinion can be arrived at. Amongst the manufactures were specimens of carving from Khurja, Saharanpur, and Bijnor, painted woodwork from Muttra, satins and pottery from Azimgarh, carpets, durries, lacquer work, and odds and ends of curiosities which native gentlemen delight in collecting.

The influence of such shows and gatherings cannot be over estimated; they are the best if not the only means by which the Government can work out the improvement of the yet unlettered millions, socially, agriculturally, and [illegible]. Whether sufficient use is yet made of them in this direction may be doubted; more might be done by a carefully worked system of supervision. But so far as it goes, that of the Bulandshahr district is the best of any of the district shows or fairs in these provinces.

AGRI-HORTICULTURAL SOCIETY OF INDIA.

The usual Monthly General Meeting was held on Thursday the 17th February, 1881.

W. H. COGSWELL, ESQ., *President, in the Chair.*

THE proceedings of the annual meeting were read and confirmed.

The following gentlemen were elected ordinary Members :—

Messrs. C. Duke, W. Martin, T. J. Kallonas, and Bhupendra Bahadoor Sing, Rajah of Kuntil.

Honorary Member.—Mr. T. Lewis Bernays, V.P., of the Queensland Acclimatisation Society.

The names of the following gentlemen were submitted as desirous of joining the Society :—

Major the Hon'ble E. Baring, R.A , C.S.I.,—proposed by the President, seconded by Mr. G. L. Kemp.

H. H. Shiwaja Rao Holkar, first Prince of Indore,—proposed by the President, seconded by Rajah S. A. Ghosal, Bahadoor.

C. E. Fendall, Esq., Forest Department, Phillour,—proposed by the Secretary, seconded by Mr. S. H. Robinson.

Baboo Lalit Mohun Roye, Zemindar of Chakdigrah,—proposed by Mr. F. Wyer, C.S., seconded by Baboo P. C. Mittra.

Edward Poppé, Esq., Calcutta,—proposed by Mr. W. H. Cogswell, seconded by Mr. J. W. O'Keefe.

R. Williamson, Esq., Messrs. Finlay Muir & Co.,—proposed by Mr. Cogswell, seconded by Mr. W H. Pigott.

Baboo Hem Chunder Gossain, Serampore,—proposed by Baboo Joykissen Mokerjee, seconded by Baboo P. C. Mittra.

The General Manager—Indian Glenrock Gold Mining Company, Devala,—proposed by Mr. S. Jenings, seconded by the Secretary.

Re-joined.—Thos. Hindmarsh, Esq., Kanchraparra, F Schiller, Esq., Calcutta, and the Hon'ble Mr. Justice Cunningham.

CONTRIBUTIONS.

Seeds of Cypress and Cryptomeria. From the Superintendent Botanic Garden, Saharunpore.

A small assortment of seeds from Botanic Garden at Trinidad. From the Director.

A healthy plane of *Cyclamen Persicum.* From T. M. Francis, Esq.

A plant of *Magnolia grandiflora.* From C. Nickels, Esq.

Seed of *Cassia magnifolio* and of a good species of *Musa.* From L. A. Bernays, Esq.

ANNUAL FLOWER SHOW.

The report of the Judges (Dr. G. King, Messrs. G. L. Kemp, W. Pigott, and Baboo P. C. Ghose) on the Show of Flowers held in the Society's Garden, on the 3rd February, was submitted—

. . . .

The Council reported that the usual annual show of vegetables and fruits could not be held last month in consequence of the lower basement of the Town Hall being occupied, and there being no other covered space of sufficient size, in a centrical position suitable for the purpose.

POTATOES FROM MELBOURNE.

The Secretary mentioned that having obtained a small consignment of potatoes from Melbourne (32 maunds) in tolerably good condition for planting out, he had lost no time in transferring the whole, at prime cost, to Messrs. Lloyd & Co., who had immediately despatched them to their Tea Gardens at Darjeeling, and promised to communicate the result in due course.

MANILLA HEMP.

Submitted the following circular from Surgeon-General Edward Balfour on the subject of the Manilla Hemp plant:—

Mr. Liotard, of the Agricultural Department of the Government of India, has this year (1880) reported on the materials in India, suitable for the manufacture of paper. Several of the fibre-yielding plants are mentioned by him and, amongst others, various species of the genus *Musa*, of the plantain or banana tribe, many of which have been grown in the East Indies from the most remote times. At pages 54 to 58 he describes the introduction, in February 1858, of the Manila hemp plant, direct from the Phillipines, into the Madras districts, by Colonel (now Sir George) Balfour. Nevertheless the Import Trade Returns of the United Kingdom show a large and continually increasing delivery of hemp from the Phillipine Islands now averaging yearly about 20,000 tons. valued about half a million of sterling. I have ascertained from the London Produce Brokers through Dr. Birdwood of the India Office, that this important article is the true Manilla hemp from the *Musa textilis*, that the bulk of it is delivered in London, where it is made up into cordage and ropes for ships, especially for yachts' running rigging, being very light, strong, and clean, and also for clothes lines. But there is no doubt that the Manilla hemp plant, *Musa textilis*, grown as well in British India as other species of the plantain or banana genus, and that British India could, in a couple of years, supply the London market with all that it could take of Manilla hemp fibre. The prospect of benefiting British India by creating an export trade from it of the extent and value above indicated, might well incite to considerable efforts to attain success. In 1861 to 1863 the Madras Revenue Board made continuous efforts to secure the naturalisation of the plants which Colonel Balfour had introduced ; but their efforts seem to have been effectual only in the Wynaad, from which, by 1877, the Conservator of Forests replied that the Phillipine variety had been introduced on several of the coffee estates, where it grows remarkably well, and no doubt is felt there as to the value of its fibre. The attention of the Boards and Commissioners of Revenue, and of the Agri-Horticultural Societies might be re-directed to this plant.

Year.		Cwt.		£
1877	..	332,304	..	488,069
1878	..	421,160	..	551,856
1879	..	337,687	..	434,037

The Secretary stated that *Musa textilis* was grown for several years in the old garden of the Society, but it did not progress satisfactorily, and the cultivation was eventually abandoned.

MUNJEET.

Read a letter from Messrs. J. Perrin of Berhampore seeking information regarding the article Munjeet. "Can any one of the Society"—writes Mr. Perrin—" give me some information regarding a plant called Munjeet (vern. Munjista) ; It is much used by native dyers as a substitute for madder, and like the latter gives fast colours. It is usually imported from Assam or Bhootan, I am told, but so irregularly that at times (it is the case now) it is impossible to procure in Calcutta or elsewhere. Perhaps you or some Members of of the Society might know whether the plant could be cultivated in Lower Bengal. If the attention of the tea planters of Assam, Darjeeling, or of the Hill Stations was called to the usefulness and mercantile value of the plant, they might introduce it in their garden. I hear it is now exported from Calcutta."

The Secretary submitted a full memorandum on the subject which he had sent to Mr. Perrin, who thankfully acknowledges it, and "the most interesting and useful information it contains. We use here Munjeet regularly for silk printing, but as it is imported very irregularly from up-country, we remained months without being able to procure some ; hence my wish to inquire whether it could not be introduced in the plains, but I see it is out of the question."

Agreed that this memorandum be published in the Number of the Journal now in the press.

OPIUM CULTIVATION IN THE HIMALAYA.

Submitted the following remarks from Captain J. F. Pogson on this subject :—

British India, with its varied fertile soils and climate is capable of producing sufficient opium of all kinds to supply Europe, Asia, Africa, Australia, and all America.

The demand for first class opium for medicinal purposes increase daily ; and, though the Himalaya cultivators are able to produce it, no effort is made to throw this most valuable description of opium into the London market. The bunneahs have the entire poppy cultivation and opium trade in their hands, and the practical result is their enrichment and the hopeless impoverishment of the cultivators.

I will give an example on the large scale. In the British Himalayan province of Kishteewar, miles and miles of land are annually placed under poppy culture. The very large quantity of first class opium which results is sent, or smuggled into China, *viâ* Ladak and Thibet ; and thus a leak of perhaps not less than fifty lakhs of rupees is steadily taking place in neglected and unknown portions of opium-producing British territory.

The Thibet and Hindoostan road, begins at Kalka, and the tracing ends at *Shipkee* on the Chinese Frontier. A road, such as it is, connects *Kishteewar* with the valley of the Sutledge in Kanawur, (Upper Busahir) and so join the Thibet road line. Now if a regiment of Pioneers were sent to open out and improve the existing road, and another half regiment of Pioneers were sent to open the road to *Shipkee* so as to fit it for mule traffic, the opium of *Kishteewar*, produced under the superintendence of an opium Agent (B.C.S.) could be sent to *Shipkee* and a regular frontier trade in opium and merchandise established between British India, *viâ* Simla and China. Of course every inducement and facility should be offered to Thibetian and Chinese traders to visit Simla ; and, as it is perfectly legitimate for the Government of India to convert an illicit intra-Himalayan opium trade with Thibet and China into a legitimate traffic, all parties concerned would be benefited, and the Government especially so.

The *Kishteewar* poppy cultivation would be taken out of the bunneeah's hands and all the zemindars released from their thraldom. The production of first class medicinal opium for export to Europe and America would speedily follow ; and as such opium should be sold at a Government Opium Mart to be established at Umritsur, the representatives of London firms would purchase, readily and largely, an opium rich in morphia and other valuable medicinal alkaloids extant in superior opium but deficient, or entirely absent, in the opiums of Bengal and Behar.

I maintain that it is quite possible for the Indian Opium Revenue to be increased to twelve millions sterling from its present figure, leaving Malwa opium duty out of the calculation. But to secure such results, action, and not useless and prolonged correspondence should be the course selected for adoption.

Letters were read—

1. From Major S.S. Jacob ex-Engineer Jeypore, enclosing a letter to his address from Dr. Schweinfurth of Cairo, asking for certain seeds, and offering to reciprocate.

The Secretary mentioned he had been able to meet this requisition partially, through the kind assistance of Dr. King.

2. From the Director, Department of Agriculture, N.-W. P., applying for a certain quantity of American Cotton seed. Application put in hand.

3. From the Manager, Ceylon Company, "Limited," acknowledging receipt, in excellent condition, of a quantity of *Ficus elastica* plants.

4. From Dr. Geo. Henderson, Rawul Pindi, suggests the distribution by the Society of seeds of *Pinus longifolia* throughout India. The tree thrives well—" remarks Dr. Henderson" in most parts of India, down as far as Purneah, and I think it has succeeded about Calcutta. The only difficulty about raising the trees is that they take about two years to attain a height of one foot, and if the top is injured, their growth is greatly retarded. There is no tree in India more worthy of cultivation, whether for shade, ornament, fuel, or timber, and it thrives from Peshawur and Calcutta. I would suggest that you call the attention of Railway officials to it ; they might grow it all along their lines and at Railway Stations." (Application for seeds made to Superintendent Botanical Garden, Saharunpore.)

5. From the Conservator of Forest, Central Provinces, applying for a small quantity of indigo seed. (In course of compliance through the kind assistance of Messrs. W. Moran & Co.).

6. From the Director, Department of Agriculture, North-Western Provinces, applying for information in respect to judging the merits of ploughs and their working, in anticipation of experimental ploughings which are about to be made in certain stations. (Complied with through the kind assistance of Dr. Lynch.).

7. From Capt. J. F. Pogson, returning thanks for his election as an Honorary Member.

8. From L. A. Bernays, Esq., notifying his resignation of the office of V. P. of the Queensland Acclimatisation Society, and expressing his willingness notwithstanding, to continue to render any aid in his power to the Society. Mr. Bernays has been most kind for some years past as his contributions to the garden will shew, and his offers are thankfully accepted.

9. From Capt. Pogson, respecting the introduction of certain food grains and economic plants into the Himalaya. (Transferred for journal now in the press.)

10. From the Secretary, British Indian Association, acknowledging receipt of one hundred copies of extract from the Society's Annual Report, and promising to distribute them.

11. From Messrs. Sutton & Sons, Reading, in reply to complaint of the non-germination of many of the flower seeds supplied last year. The following extract of their letter :—

"We exceedingly regret to hear that you have unsatisfactory reports about some of the flower seeds.

We are quite at a loss to account for it, and should be greatly obliged to you if you could give us every possible information on the subject.

We have kept particulars of every sort of seeds sent, and can trace each one to the grower.

We never took more pains than we did last year in the execution of the order. In fact as our foreign trade is rapidly increasing we are extending our facilities and have a special staff now always engaged in the work. Every lot of seed sent you was proved to germinate well just before it was packed and that it should have gone off growth so soon afterwards is inexplicable to us.

We can only suppose that the disastrous harvest of 1879 has something to do with it; and that though the seeds grew well enough for the first six months after they were gathered, yet that we had not sufficient sun to thoroughly mature them and enable them to retain their growth until they were sown in India full 12 months afterwards.

Any way we can assure you that we esteem it such an honor to supply your Society, that it is with the greatest possible regret we learn that we have not been successful this season as in previous years."

For the above communications and contributions the best thanks of the Society were accorded.

MINERALOGY.

A COMPANY is being formed locally for the discovery of gold in the Bombay Presidency. The precious metal is supposed to exist in the Southern Mahratta country.

THE Lahore paper says that the Palamow Railway and Coal Field scheme is all but sanctioned by the Supreme Government.

SAYS the *Madras Times* :—Arvenghaut, of Brewery fame, it is reported, contains gold. This valley, as our readers know, debouches into the Coonoor ravine, and has always been reckoned admirably adapted for a tea or cinchona estate. Mr. Withers has discovered gold on the Brewery ground, and it is believed that an offer for the premises of Rs. 60,000 was refused.

IN our last issue we stated that the Japanese Government had indented for a large amount of mining machinery from San Francisco to develope the gold mines on the Island of Sado. We now learn that—

To a small extent, these mines have been worked by machinery for the last ten years, altogether at a loss from a financial point of view. The main shaft is sunk to a depth of 600ft., and two of the mines are connected by a gallery 3,000ft. in length. The ore contains from 50 to 2,000 yen worth of gold per ton (one yen equals 4*s*. 3*d*.) During the last year the amount of ore reduced was 6,428 tons, yielding 2,196 oz. of gold, and 91,743 oz. of silver, at an expenditure of 85 per cent.

THE *Siam Advertiser* mentions that reports were current in Bangkok that gold has been discovered in one of the northern provinces of Siam, and that a rich specimen was recently brought to Bangkok. The great mineral wealth of the country has long been known, although, like the diamond deposits of Borneo, the locality where it has been found to exist is systematically concealed, and hence these mineral resources are likely to remain undeveloped for many years to come.

IN his annual report of the Department of Mines, New South Wales, Mr. Thomas Richards of Sydney says, that the falling off in the yield of gold in the colony is due to causes other than exhaustion. The principal causes, probably, are the small number of persons now engaged in gold mining; the want of means or enterprise to carry on extensive exploration; the gradual exhaustion of such of the deposits within the older gold fields as are within the reach of the miner unaided by capital; the want of capital, appliances, and skill to work systematically and economically those deposits which cannot be profitably worked without their aid.

GOLD-MINING is an industry that is attracting great attention in Tasmania. At a small township in the vicinity of a paying gold field, which a short time ago was a wild jungle, land for building allotment has been sold at £920 per acre. A recent quartz crushing at the Royal Tasman Reef in the Mount Cameron country, hitherto known as a mining district which no one suspected contained even the colour of gold, yielded over 20 ounces of gold to the ton; and several other valuable reefs have been discovered in the neighbourhood.

IT is common to consider the quantity of gold in the world to be large. But there is only £7,000,000,000 worth, which is about half pure gold and half silver. The annual production is about £100,000,000 worth, and the production has decreased 44 per cent during the past thirty years. The production of silver, however, has increased 100 per cent, and now equals that of gold. One-third of the gold goes to wear-and-tear, one-third goes into circulation, and one-third into arts and manufactures. All the gold in the world would make a pile only 25 feet wide, 45 feet long, and 25 feet high.

PETROLEUM IN ARAKAN.

THE report on Revenue Administration for British Burmah 1879-80 has just been published, and contains some interesting information regarding the earth-oil trade of Arakan. The Borongo Oil Refining Company, Limited, seem to be the largest workers with suitable machinery. They have as yet only disposed of small parcels of the crude oil in Calcutta, Rangoon and Chittagong, and they experience powerful opposition from the holders of the King of Burmah's oil monopoly, who always have a large stock on hand which they sell dear or cheap according to there being any other oil in the market. As yet it is too early to speculate on the success or otherwise of the Company, but with a proper refinery at work, if they only get a sufficient supply of the crude oil, they should be able to undersell any imported article. Several oil wells are worked by Arakanese in a rude fashion in the Akyab district. In one instance an Arakanese who said he had paid Rs. 700 for a well, acknowledged to having made a profit on its working of Rs. 2,000 in the space of one year. Many of these wells, imperfectly sunk as they are, yield from 5 to 6 maunds of crude oil a day. The oil obtained in the Akyab district wells differs considerably from the Borongo oil which is the colour of brown sherry. The Akyab wells produce a greenish grey oil said to be much richer in lubricating qualities, and for that reason sought after for various manufactures. It is said to be used extensively in some process of jute manufacture, and the attention of some firms in Calcutta and Chittagong has been directed to it, whilst the Commissariat Department have also given extensive orders for it.

FORESTRY.

ON the 21st January last, Sir Richard Temple at the Society of Arts read a paper on Forest Conservancy in India. Sir Richard said that in this country about 60,000 square miles of land were in charge of the Forest Department, and that in a short time the area would extend to 100,000 square miles in Southern India and Burmah. The meeting was also addressed by Dr. Cleghorn, Sir Joseph Fayrer, Sir William Robinson, and others. Dr. Cleghorn, it may be remembered, about twenty-five or thirty years ago had charge of the Forest Department in the Madras Presidency. It was he who impressed upon the consideration of the Government the great necessity for carrying out an effective system of forest conservancy which has now grown into a large and important department. We shall endeavour to give a *resumé* of Sir Richard's paper in our next number.

IT is stated by the Famine Commissioners in their Report, that only about 24,000 square miles out of the 1,472,857 square miles of forests contained in British India, are as yet absolutely protected from injury, and devoted strictly to legitimate forest uses under special legislation. As to the Madras Presidency they say :—"It is much to be regretted that the introduction of a Forest law has been so long deferred in Madras, and we trust that measures for protecting the existing forest tracts from denudation, and for obtaining power to reserve suitable areas for pasture, which may be so important in their relation to future seasons of drought, will speedily be undertaken in Madras with the same energy and judgment which are being displayed elsewhere."

TWO German philosophers have discovered that the trunks of trees undergo daily changes in diameter. From early morning till early afternoon, there is a regular diminution till the minimum is reached, and the maximum diameter is attained at twilight. Then succeeds a diminution till an increase is noted at dawn,—an

increase more marked than at twilight. The variations are found to be inverse to the temperature, the maximum of the one corresponding with the minimum of the other, and so on.

THE CAMPHOR FORESTS OF SUMATRA.

THE *Straits Times* has the following interesting description (translated from the Batavia *Dagblad*) of the trade, especially in camphor, between Baros (W. Sumatra) and Singapore, written by a correspondent at the former places.

" The Chinese here are doing a good business in benzoin, gutta, rattans, and camphor, which are brought down in great quantities by the independent Battaks from their forest clad mountain, and which are, to this day, mostly exported to Singapore without there being any bother about customs export duties; buffalo hides, in which, however, the transactions are few, being the only article subject to an export duty. The Battaks bring the three first named valuable articles in plaited rattan baskets, which they carry slung from the extremities of a bamboo laid on the shoulder. As return freight they bring away from this, much salt and other necessaries. The appearance of the Battaks I saw here was not particularly pleasant, and they excited my antipathy, especially from the circumstances that actually, though to a limited extent, they are cannibals. The camphor of Baros is renowned throughout all Netherlands India, and has given its name (Kapur Baros) to all sorts of this article of trade. It distinguishes itself by its peculiar strength and a relatively trifling amount of volatility. Under similar conditions a given quantity of Baros camphor loses by evaporation only a fourth part of its weight, in the same time that as large a piece of Japan camphor wholly evaporates. Hence the former is an article in great demand, and brings high prices. Not unfrequently Baros camphor is sold at Singapore for 10,000 guilders per picul. Especially amongst the wealthy Chinese there, it is greatly in demand for embalming the bodies of their relations whom they intend to send to China for burial in their native land. It is found in small crystallised pieces and thin layers amongst the fibres of the camphor wood, and is usually offered for sale in that condition after removing the coarser woody articles and other foreign matter. Trees containing a very considerable quantity of this costly product are comparatively rare. Most of the camphor trees contain it in such a thinly distributed condition that it can be only extracted by boiling, as is the case with the Japan description. The Battaks are very skilful in finding out trees abounding in camphor, and dislike the slow boiling process. They, too, desire greatly to earn as much money as they can in the shortest possible time, in order, afterwards, to enjoy a longer rest. In Sumatra, camphor wood is not only used for making the boxes by which many persons who have returned to Europe are recognised there, when travelling, as being from the East Indies, and according to which are determined the prices they have to pay at lodging houses, &c.; but also as timber. That people are not sparing with it, is apparent from the fact that the great bridge over the Batang Taro river, now under construction, is wholly made of this wood. Although not particularly hard, it is of great use for building purposes, because many species of insects, the white ant being the most dreaded, which in these districts manage to destroy all other kinds of wood with wonderful rapidity, leave the camphor wood untouched. The smell of camphor is plainly perceptible in the chips which fall off on preparing the wood, and even in the leaves though not very strong when rubbed small.

It is a pity, however, that the natives living in the midst of this bountiful gift of Nature are using it up so carelessly, that, if they are not in time brought under control, an end will soon come to this productiveness. At present, the dense forests of Battak Land still contain hundreds of thousands of camphor trees, but the Battak cuts away recklessly, without a thought of the future, and without planting fresh camphor trees. In the same way an end will soon come to the present large stock of gutta in the Sumatran forests. What is found most abundantly in these districts to the East of Baros and Singkel, is the valuable benzoin, that fragrant gum which is utilised for incense and other scents. I saw astonishing quantities of it in the Chinese warehouses at Baros. In hundreds of cases this article is shipped to Singapore—that centre of the trade of the Far East. The benzoin is bought, unprepared, from the Battaks, usually at 1·40 guilder per catty. The scent of this gum is very agreeable, and it is a pleasure to stay in the store-houses, where it is sorted and then carefully packed after being plentifully sprinkled with water. Remarkably enough, the Battaks take great care that other benzoin trees shall rise up to replace those cut down. For in fact, they have nothing else to do than to burn the stumps and scatter the seeds in the ground. The planting of gutta and camphor trees appears to require more trouble and care,—more at least than is compatible with human labour and duty in the opinion of the Battaks."

GARDEN.

THE coming mango season in Bengal, it is expected, will be one of great plenty. Up to the present time the mango groves all along the railway line from Rajmahal to Howrah give fair promise of an an abundant crop.

THE vintage of France for 1880 was an unsatisfactory one, and the effects of the vine disease are still being severely felt. The yield last year was 2,000,000 hectolitres below the average of the last ten years. The imports in consequence have risen very rapidly. For the first eleven months of 1880 they reached [illegible] hectolitres. Prior to 1878 they had never amounted to [illegible].

THE Frenchmen who believe in the possibility of converting sunshine into mechanical power, are continuing their experiments in Algeria. They are adapting the solar boiler to the distillation of alcohol from Barbary figs. Of course there will be no expense for fuel; the figs cost next to nothing; the refuse serves as food for cattle; and alcohol will be produced at the rate of two hundred litres a day. Much advantage is anticipated; for at present Algeria imports thirty thousand hectolitres of alcohol.

THERE are 400 orange groves in the neighbourhood of Jaffna, which are irrigated, the machines for the purpose working day and night for seven months in the year. The expense of working and watering an orchard is £40 per annum, and 5,000 people are employed on the 400 gardens in the picking and packing alone of oranges. Could the cost of irrigation be cheapened, the number of gardens would probably be doubled in a short time.

AZALEA MOLLIS.

EVERY year confirms the opinion we gave in these papers some years ago that this would prove an invaluable plant for winter flowering by means of forcing. It is now annually imported from the Continental nurseries for forcing by thousands. It is especially useful for conservatory decoration, being less useful for cutflower purposes, owing to its liability to fall soon after being cut, except the flowers be gummed immediately. The beautiful tints of colour, every one of them soft and pleasing, form fine accompanying contrasts to the higher coloured hyacinths, rhododendrons, scarlet pelargoniums, and Ghent and Indian Azaleas, with which they are usually associated in the conservatory in winter time. The same plants may be forced year after year successfully, if carefully managed and cultivated during the growing season which succeeds the flowering season. They are generally ruined for want of the necessary care and protection during the cold months of winter and spring that follow after the forcing period. When flowering is over, they should be placed in a light and comparatively airy position. If necessary, also, they should be shifted into large sized pots at this time; but they may be grown well in comparatively small pots, as one of seven or eight inches diameter is capable of accommodating a plant carrying forty or fifty heads of flower. They should undergo a gradual hardening process in May, and be placed out of doors in June in a sunny spot, where they will enjoy shelter from strong winds Keep them well supplied with water till their leaves begin to change colour, when it should be gradually withheld to prevent any inducement to premature growth, which in forced plants is very liable to occur if autumn is prolonged and warm. The better to prevent this, they should be placed behind a wall or hedge facing north. Throughout the growing period they should be treated to mild liquid manure three times a week.—*N. B. Agriculturist.*

THE ORIGIN OF THE TOMATO.

MANY Americans think that the luscious tomato had its origin in this country because it is so freely used here, and that it has become quite recently an article of food. The origin of the vegetable, or fruit, as some claim that it is, is not positively ascertained, though there is reason to believe that it was first found in South America, and that it was cultivated centuries ago in Mexico and Peru. Several varieties were known in England towards the close of the sixteenth century, and Gerard, the surgeon and botanist, speaks of it, we think, in his "History of Plants," having himself introduced it into the Kingdom as an exotic. Dodens, the Netherland herbalist, mentions the tomato as early as 1583 as a vegetable to be eaten with pepper, salt, and oil. It belongs to the nightshade family, and was used in cooking by the Malays more than a century and-a-half since. It is extensively raised in Southern Italy, and employed there as an accompaniment to nearly every dish, particularly to macaroni. But neither there nor anywhere else in Europe is it commonly eaten, as it is here, separately and in quantities. In England it is a sparingly produced, requiring a hotbed in spring, and in consequence is high-priced. The Italians formerly called it golden apple, and now call it love apple, as it was once designated in this country. The appearance of the tomato on the table has greatly increased in Europe in the last few years; but in no land is it a regular dish—much as it is used for sauce abroad—as in the United States where it is also pickled, preserved, and confected.—*American Paper.*

CHENOPODIUM A SUBSTITUTE FOR ASPARAGUS.

THIS old English vegetable has gone out of cultivation very much during the past half century, though it is still grown by a few gardeners at home, by whom it is generally known under the name of Mercury, the best variety being that named by botanists "*Agathophytum Bonus Henricus*" or good King Henry Mercury. Its virtues as an esculent vegetable delicacy seem to be best acknowledged by the farmers in Lincolnshire, nearly all of whom have a corner devoted to its culture. It is said to be as good as Asparagus, though not quite so large in growth: but it is much earlier, being ready to cut from a month to six weeks before that vegetable. It is questionable if every one would be prepared to pronounce the flavour as good as that of Asparagus, but still it is very nice. When ready to cut, the shoots are about the size round of the little finger, and should be cut under-ground in much the same manner as Asparagus. The skin is sometimes tough, in which case it

has to be peeled off from the bottom upwards, and it is then washed and tied up in bundles. It is usually boiled in plenty of water with a good handful of salt in it, and when boiled tender it is served up simply, or upon toast, or with melted butter; or with the gravy of meat. The ground should be trenched two feet deep, and have a good lot of manure mixed with it. The plants which are perennial must be raised from seed and planted out in May to July in rows eighteen inches apart and one foot between the plants. The first cutting of shoots may be made in August or September of the second year, but the plants must not be dealt with too severely, but after that the bed will become very thick and will then yield a great quantity of shoots. They will grow much better in the cooler districts of the hills, where the beds can be formed on the drier portions of the rich alluvial swamps. During the growing time the bed should be watered with liquid manure if possible. The leaves make a very good substitute for spinach. Several of the varieties of *Chenopodium* are cultivated for food and some roots are burned for soda, as for instance *C. maritima*, *C. anthelminticum* produces a flower spike from which the worm seed oil so much used in the United States as a vermifuge. *C. quinoa* is indigenous to the Pacific slopes of the Andes, and it is largely cultivated in Peru and Chili for its seeds which are much used as an article of food. The seeds are albuminous, and when boiled make a kind of gruel which being flavoured with Child pepper is considered to be very nice by the inhabitants of those countries, though to Europeans it is very disagreeable. This plant bears great quantities of seed.—*Adelaide Observer.*

OPERATIONS FOR MARCH.

I.

IN HILL STATIONS.

THE FLOWER GARDEN.—Prune Roses. Sow grass seeds for lawns. Fork, rake, and dig beds, borders and shrubberies. Complete pruning of Clematis, Bignonias, Jasmines, and Creepers, and give the garden a neat appearance. Plant Hardy Gladoli. Sow Flos Adonis, Calandrinia, Calliopsis, Campanula, Centauria, Chrysanthemum, Clarkia, Collinsia. Convolvulus-minor, Erysimum, Larkspur, Linum, Amaranthus, Lupins, Œnothera, Poppies, Saponaria, Sweet-peas, Venus' Looking-glass, Veronica, Virginia Stock, Viscaria, Pentemon, Foxglove, China Aster, but half-hardy annuals are perhaps better left till the following month. Pot off all bedding plants and keep them close for a week or more. Increase Dahlias by cuttings, this is the best month for it. Place Carnations in blooming pots.

THE VEGETABLE GARDEN.—Most of the principal crops must be got in now. Manure, trench, and dig soil deep. Devise a plan of how your garden is to be laid out and economise space. It is a little too early for Celery. Jerusalem Artichokes should be planted now, and Globe Artichokes should have their offsets taken off. Sow Carrots, Cabbages, Cauliflowers, Brocoli, Radishes, and Peas. French Beans should be shown at the end of this month.

II.

IN THE PLAINS.

THE FLOWER GARDEN.—Gradually let Dahlias and Oxalis die down by withholding water. If Gloxinias, Richardia, and Lilium have done flowering, withhold water and let them die down, and leave them as they are in the pots. Cut back shrubs that have done flowering, and take up Verbenas in pots to protect from severe weather and rain which will fall in May.

THE VEGETABLE GARDEN.—Onions, if perfectly dry may be taken up now, if not then next month. Carrot and Beet may be taken up now and stored in sand, or it may be deferred to next month.

In the North-West, Cucumbers and Squash may be sown now. Top dress Asparagus beds. Dry the leaves of pot-herbs and store them in stoppered bottles.—*Indian Amateur Gardener.*

TEA.

THE exports of Indian tea to Great Britain during January last, were 4,900,555lbs, against 3,485,754lbs, in January 1880. The London deliveries during January last, were 4,100,000lbs., against 3,300,000lbs, in January 1880, while the stock held had on the 31st of January increased by 2,700,000lbs.

THE total quantity of tea shipped to America from Japan last year was 83,000,000lbs. As a rule the quantity shipped in former years has averaged 65,000,000, so that either too much has been exported or the demand has considerably increased. Again, until this season the export of China tea to America has always exceeded that of Japan, but the reverse has been the case this season.

THE Japanese tea merchants are endeavouring to secure the American market for their tea. We read in the *Overland China Mail* that a number of Kobe merchants have formed a Company for the export of tea to the United States, and to despatch agents there to carry on an extensive business in that country. The question of combinations to defeat the object of all sales by auctions is attracting the serious attention of auctioneers and the public generally in Yokohama.

WE learn, says a Rangoon paper, that the exhibits of tea at the Melbourne exhibition sent from Akyab last year obtained a high place among the various specimens of tea sent from India. It is a pity some of the Karen Hill tea was not also sent; for the few pounds of it we have tasted, has given us a high opinion of its future prospects. Even now when the curing of this tea has been effected by a comparative amateur its flavour is a fine one; but with the opening of the Toungoo Railway when we may expect cultivation to be so extended as to induce planters to employ skilled labour, imported from the tea districts of India, we think that the rich virgin soil of the Karen Hills will yield an article which may vie with any of our Indian teas in aroma or otherwise.

IT is an undeniable fact, that between the time of tea being grown in China or India, and retailed in England, some five or six large intermediate profits are made on the article. The consequence is, the fine qualities are enhanced to such high prices as render them unsaleable, and inferior or second crop teas have thus to be retailed, showing in many cases an aggregate increase on the original cost of the tea to the grower of fully 100 per cent. To rectify this, and to give the benefit of wholesale prices to retail purchasers, a Tea Agency has been started close to Mincing-lane for the purpose of buying only the choicest kinds first hand, and selling them, first hand. It is declared by the promoters of the Agency that they are enabled to supply tea of intrinsic value fully 10*d.* per lb. cheaper than inferior kinds usually retailed at more money.

THE following figures relating to the supply of Indian tea, will, says the *Home and Colonial Mail*, perhaps, prove of interest to our readers, as the forecast shown of a probable stock of only 13¾ million lbs on the 30th June next, may not improbably be realized :—

	1880 Season.		1879 Season.
	1st July to 31st December.		
Imports	28,143,000	...	20,088,000
Deliveries	22,150,000	...	16,849,000
Increase of Imports over Deliveries ...	5,993,000	...	3,839,000
Present Stock		...	20,223,000
Estimated Imports to 30th June 1881		...	16,000,000
			36,223,000
Deliveries at say 3,750,000 per mensem		...	22,500,000
Probable Stock 30th June ...		...	13,723,000

THE consumption of teas, has been as follows, in lbs, per head of the home population :—

	China. lbs.	India. lbs.	Total. lbs.
1860 ...	2·622 ...	·038 ...	2·660
1865 ...	3·163 ...	·097 ...	3·260
1870 ...	3·396 ...	·443 ...	3·839
1875 ...	3·728 ...	·712 ...	4·440
1878 ...	3·533 ...	1·087 ...	4·620

The average increase in consumption of Indian tea amounted to about 1¾ million lbs per annum. It will be observed too, that while the consumption of Indian teas has steadily increased during the last eighteen years, that of China tea has not increased since 1873, when it stood at 3·531. It reached its highest point in 1875, when it was 3·728, since which year it has steadily declined. The turning point in Indian teas having thus been reached, it behoves all concerned to make an effort to keep up, and even improve the quality that it may retain and extend the position it has secured.

Now that it is in contemplation to try to open up trade in Indian tea with America, it may be of interest to our readers to learn that during the year ending 31st December 1880, the number of packages of tea distributed in America was 232,647. The figures showing the deliveries of tea in the United States for the past twelve months are as under :—

Greens.	Japans.	Oolongs.	Congous.	Total.
16,667,000	35,949,000	14,079,000	4,511,000	71,206,000

In 1879 the figures were as under :—

17,826,000	33,380,000	19,321,000	4,157,000	74,184,000

There has thus been a falling off in the consumption of tea in America on the whole, although the trade in Japans shows an increase of 2,569,000lbs. The demand is noticeably for the better grades in all kinds.

IT appears that during the years 1878-80 no less than 5,42,433lbs (over 7,030 maunds) of China tea, valued at Rs. 2,82,000 were imported into Calcutta. The previous year the quantity of China tea imported was 437,588lbs; so that while the Indian tea exports increased, the imports from the "Flowery Land" have shewn an upward tendency. It is difficult to account for this, but probably one of the most important reasons is the high prices charged for Indian tea by the Calcutta retail dealers. We have a retail adver-

tisement before us from one of these establishments, in which it is announced that Pekoe Souchong can be obtained at Re. 1-8 per lb and Souchong at Re. 1-2. Considering that at the public wholesale auctions Pekoe Souchong has never realised as much as Re. 1 per lb this season, it appears to us that the retail tea trade in Calcutta if a limited one, is certainly most remunerative to the seller on every transaction in this article. The China tea imported was worth on an average a little over $1\frac{1}{2}$ lb for the rupee. Calcutta retail dealers ought to be able to sell a very good average Indian Pekoe Souchong at this rate and net a fair profit.

At the present time, when there is such a remarkable outburst of private and personal energy in the endeavour to popularise the use of Indian tea among the English people, it is worth while to notice an accusation made against the Indian leaf which has become common in middle-class circles. It is asserted that a "gummy, gaseous-looking coat of film" settles and floats on the top of an infusion of Indian tea, most visible when the liquor cools. Those whose prejudice is easily alarmed profess apprehension of the wholesomeness of this appearance, although a good many professional tasters declare in favor of the quality of the teas which produce it, and value them at the best rates. When a solution of Indian tea is allowed to become absolutely cold, "a thin layer of dull, whity-brownish matter, more dense than the liquor itself," is formed at the top of the vessel, and changes to a darker colour the longer it is left to stand. It disappears on the re-application of heat. Hence it is supposed to be a vegetable gum existing in the tea. Experts in China tea aver that this fault in Indian tea is due to the method of curing the leaf. In India, it is alleged, teas are only partially "fired." The young leaves, full of moisture, not being heated above a certain temperature, are left with minute particles which contain the offending gum. The China tea, on the other hand, is dried as much as possible without positively injuring the leaf, and every trace of limpness is removed, leaving the leaf crisp and brittle. As the "cloudiness" to which reference is made unquestionably hinders the popular use of Indian tea, the matter is well worth attention on the part of growers and curers.

TESTING TEA LEAVES.

How to Tell Pure Tea.

Take a sample of tea and place in a saucer; pour over it hot water, and in a short time the leaves will unfold and spread themselves out, so that their form can be readily seen. Take a piece of glass and place it on the top of a sheet of white paper; then take the tea leaves you wish to examine: and carefully lay them on the glass, so that a leaf or portion of a leaf shall be fully spread out. You are now ready to make your examination of the leaves. But we will first state that the genuine tea leaf is oblong, or broad lance-shaped, considerably longer than wide, with the edges saw toothed or serrated. The veins are simple, that is, do not branch, and run towards the side of the leaf, where they form a characteristic series of loops, especially in the older leaves. First examine the whole leaf as to size and form. Look carefully along the edges of the leaf for the notches or serrations, and note if they are deep or faint, close together or far apart, and if they extend to the base of the leaf. As to the surface of the leaf, observe whether it is smooth or downy; notice the veins closely, whether they are single or branched, and if the series of loops at the edges can be seen. Let us suppose we have made our examination of a leaf and have the following notes: Leaf large and rather broad, oblong and tapers to the base; the edge of the leaf is strongly serrated, and the notches rather close together, and do not extend to the base; the surface of the leaf is smooth: the veins are large and simple, and form a series of loops along the edges. From these facts we know the leaves are genuine tea leaves, but the leaf was an old one when picked and not very valuable. The older the leaf, the plainer become the above marks. Now, if your tea is largely composed of such leaves, or parts of such leaves, it shows the tea was a late picking, and of inferior grade. The presence of the tea stems is also a sign of inferiority. But if your leaf under examination was a young leaf of the genuine tea, it would appear long and narrow, the edges but slightly serrated, the surface would be downy and the veins would be faint, and the loops not yet formed. As the age of the leaf increases it widens, the notches become deeper, the down begins to disappear, the veins become more distinct, and gradually forming the loops. We can thus tell something of the age of the leaf by these various marks. In making an examination of a sample of tea, a large number of leaves should be examined to give a correct estimation of its value, for the tea may be mixed and contain leaves of various ages, and the proportion of these would determine its worth. If you find a leaf broader than long, it is not a tea leaf; or if heart-shaped at the base, or the edges smooth and veins distinct, or the veins branched, or the edges of the leaf deeply cut, it is fair to suppose they are leaves added for the purpose of adulteration. Much difficulty will be had in making these examinations, on account of the amount of the broken leaves present, the foreign leaves being purposely broken so as to avoid being detected.

QUANTITY AND QUALITY.

The subject of Quantity *vs.* Quality has recently occupied considerable attention in connexion with "tea" literature, and a general idea of the opinion widely prevalent on the subject, may be gathered from the following sentence, taken from a correspondent's letter to our tea contemporary. "There are no two opinions on the matter, you must, by adopting one, sacrifice the other, and that is an established fact." We are not prepared to agree with him that planters must elect which they will have—quantity or quality, as we hold they can have both. Of course, it may be true, to a certain extent, that the heavy plucking which necessarily accompanies a demand for quantity, results in a lower average price or value all round; but at the same time, we do not see why the manufacture of the finer qualities should, in any sense, be affected by the larger quantity of coarse leaf made. Suppose the gardens, otherwise much alike, to be working under different orders from head-quarters, one manager is instructed to attend to quantity, the other to quality. The former has accordingly tendered an estimate for six maunds per acre, while the latter calculates on four maunds. Now, we imagine that the two maunds of excess to be made by the former will consist almost wholly of coarse leaf. By the term "coarse leaf," we mean, of course, comparatively coarse leaf. The remaining four maunds should be as good as the outturn of the other garden. It is true that more money will be spent in manufacturing the extra two maunds, but that is a simple question of profit and loss, and the proprietors must decide whether it will pay to incur the extra expense of manufacturing this low class tea. A garden which goes in for quality only, will require a certain establishment of labour, and if quantity is wanted as well, that establishment must be increased. This granted, we cannot understand why the same attention should not be given to a "quantity and quality" estimate, as to a purely "quality" one. This is where planters frequently err. In considering this question they mistake general average for particular quality, class. Roughly speaking then, a garden working for quality only, might, let us say, produce one maund fine, two maunds medium, and one maund low class teas per acre, while one looking for both quantity and quality would perhaps make one maund fine, two and a half to three maunds medium, and two to two and a half maunds low, class teas per acre, and there exists no good reason why the fine and medium teas of the latter garden should not stand comparison with the corresponding classes of the former. The difference between good and bad tea—irrespective of class—is entirely a question of careful manipulation and factory superintendence, and if a manager finds that his bushes will stand a heavy plucking, there is no reason, so far as consideration of quality is concerned, that he should not pluck heavily. This heavy plucking, of course, pre-supposes good cultivation, and, this latter being given to the garden, we hold it to be impossible to overpluck. By a vigorous plucking we do not imperil the life of the plant, or interfere with its healthy growth, to a greater extent than may be compensated by good cultivation and generous treatment generally. If all the leaves of a bush were fit for tea-making then we might be tempted to overdo the work. It is true that the young and rapidly growing shoots alone are those we want, and that those are doubtless the very ones which the plant can least spare: but, after all, the proportion taken is so little compared to that left, that it must be difficult, if not impossible, to overpluck a bush so as to injure its health or leaf-producing character. An acre, in round numbers, contains 2,500 bushes, and if six maunds per acre be made, 24 maunds of leaf will be required, or about $12\frac{1}{2}$ ounces per bush. One of the lessons we are being taught by the present crisis through which the tea industry is passing is this, that we must work our gardens properly, and must make a much larger quantity of tea for the same outlay. The quantity that an acre can produce has long been a moot point, but, knowing that over a thousand pounds have been made from an acre, we think that planters should aim at a yield of ten maunds as an average. This would certainly entail a considerably enhanced outlay for labour, &c., but, until our gardens yield something like this, we shall not be able to show good dividends. From the official returns published by the Government, we find that the present average is not over 200lbs., or just one-fourth of what we have indicated as an object to aim at. Even if five maunds per acre were attained as an average, the tea industry would be beyond the reach of loss. Under such an improved condition of affairs, a very large proportion of cheap and low class teas would be placed on the market; but that need not give us much concern, as properly worked, there is an unlimited market in India for almost any quantity of cheap tea. To secure this market, we must unbend from our lofty ideas, and offer the masses tea in infinitesimally small quantities. A large business, as we lately pointed out, is at present done in this way in India with China teas, and we must place our cheap tea before the public, made up in one and two ounce packets, when an almost entirely new market would be opened up for us. With this large production, our teas should not cost more than five or six annas per lb. laid down in Calcutta and at this cost price, and with a market in India for cheap teas, our finer classes would secure such a position in Europe that the tea industry would be established on a firmer basis than it has ever been hitherto.

COFFEE.

The coffee crop of the season of 1880-81 has been most disappointing says the Ootacamund paper. Estates estimated to yield 60 or 70 tons gave only 4 and 5 tons, while others have absolutely no crop at all. It is a mystery what became of the fine show of blossom on some Estates early in the year. Perhaps the season of 1881-82 will compensate for the serious deficiency of this year.

The *Rangoon Gazette* says :—

Tea is not the only article which will succeed in India and Burmah; we have coffee thriving well in many a gentleman's garden here, one party having to our knowledge kept himself supplied for about a fortnight with the produce of a few coffee shrubs in his compound. As all varieties seem to thrive even in the heart of Rangoon, they should yield large crops on the Karen and Arakan Hills; in fact in any place where there is high ground. We are glad, therefore, to hear that a gentleman of Akyab has undertaken the cultivation of Mocha coffee, and we hope every encouragement may be afforded to him.

In the latest published official report (September) from the Amboyna residency, it is stated that coffee cultivation is extending there, more than 200,000 coffee plants having been set in the ground in one month in a single district. The Rajahs of Lesser Ceram have also given permission to introduce this cultivation there. In the islands of Ceram Nusa, and Haruku, the coffee trees looked well and were bearing heavily.

Mr. C. Anderson, of Muzzerabad, has written a pamphlet on fungoid disease, of which the *Madras Mail* says :—

The chief purport of it is to show that potash, magnesia, and ammonia in the form of sulphates, check and destroy Hemileia in coffee, the author says, he has used in his experiments, with excellent results, $\frac{1}{4}$ to $\frac{1}{3}$ potash, $\frac{1}{4}$ to $\frac{1}{6}$ magnesia, and $\frac{1}{5}$ to $\frac{1}{3}$ ammonia. The conclusions that he has arrived at by research and experiments, include the following :—That the cessation of growth

which precedes an attack of leaf disease, is caused by a want of ammonia and other valuable food constituents in an available form. That lime exerts a marvellous effect in setting free all the alkalies, and in converting nitrogen into ammonia: that potash, magnesia, and lime are required for the production of coffee, and are therefore removed for the soil: that certain forms of potash and magnesia (especially those combined with sulphur) are inimical to the growth of fungi. He concludes that sulphates of soda, magnesia, and ammonia, should be used immediately before the occurrence of disease: and lime should be employed early in the season, to sweeten the soil and set free its resources. He also recommends that phospho-nitrogenous manures, combined with either forms of postash, be applied to sustain and invigorate the trees.

Coffee in the shell is being exported from Java to Holland in increasing quantities. The first trial shipment of it was made by a planter in the Pekalongan residency five years ago. After finding a ready sale in Holland in the first and second years, the coffee being sold in the shell and then roasted and retailed, it became unsaleable in the third year, owing to the unpleasant taste given by the shell to the coffee. The owners, having large quantities of the article on hand, were compelled to shell the coffee in Amsterdam, and after several trials with different mills, they have organised a shelling establishment there, which has worked satisfactorily during the last three years.

The "coffee" that is being made out of dried dates threatens to become a formidable rival to the bean that grows on the coffee bush. The shares of the Date Coffee Company have gone to nearly 300 per cent premium, with every prospect of advancing higher. The immediate cause of this has been the sale of the French patent for £50,000 and ten founder's shares of £1 each, which will be the property of the Date Coffee Company, and will be entitled to receive half of any dividend which the French Company may make after the latter company have paid their shareholders 50 per cent. Similar arrangements for a like sum are being made in Germany, Austria, Hungary, and the United States, and £20,000 has been offered for the Russian patent. The date coffee can be produced at the cost estimated in the original prospectus, and the demand for it in England is so great that it can be sold at a price which leaves more than the profit upon which the calculations were based.

The following remarks on the current coffee crop in Ceylon are extracted from the Colombo *Times*:—

It has become evident from the figures shewn by ships' manifests homewards, and by the railway traffic returns, that the shipments of coffee for the current season will be the smallest on record for very many years. It is thought probable that the exports of our staple may not be more than was shipped thirty years ago, when the figures stood at about four hundred thousand cwts; and as we know that in the districts around Kandy as well as in Dimbulla, Dickoya, &c., coffee stores are nearly all empty, leaving only the crops from Uva and Uda Pussellawa to come forward, it seems probable that this unfavourable view may be realised. It is remarkable, too, how much the native coffee crop has fallen off in quantity as well as in quality,—far more in proportion even than that of plantation, accounting for much of the existing distress amongst the native population of the interior and the consequent depression of trade in the native districts.

Those who at a distance may read our statements regarding the immediate prospects of the coffee crops, should remember that ample reasons for our present short shipments are to be found in the very unfavourable blossoming season in the early months of last year, and that, apart from this and the passing effects of leaf disease, we are warranted in saying, especially in looking at the present condition of the coffee districts, that there is nothing in these facts to lead to a desponding view of the coffee enterprise at large. Competent authorities gave it as their opinion last year that, had we been favoured with seasonable weather, similar to that which gave us the large crops of previous years, Ceylon would have exported a very handsome crop—sufficient to have restored confidence to capitalists and mortgagees.

PROFESSOR STEVENSON MACADAM ON LEAF DISEASE.

Analytical Laboratory, Surgeon's Hall, Edinburgh, 20th November 1880.

W. M. Fraser, Esq, of Bunchrew,

Dear Sir,—I beg to report to you that I have carefully considered the whole question of the coffee leaf-disease, and have studied the various scientific documents and papers which have been published on the subject, expecially the communication of Messrs. Morris and Ward on the Natural History and Botanical bearings of the disease. I have also made myself acquainted with the general literature of the subject as published from time to time in the *Ceylon Observer*, and have an intimate knowledge of the chemical wants of plants, including the coffee plant, for their healthy and vigorus sustenance and growth. I have likewise analysed various soils from coffee plantations in Ceylon and know the chemical constitution and properties of such. With these data before me, I will endeavour to express a chemical opinion as to the measures which may be followed in alleviating, and, if possible, in stamping out the coffee leaf-disease. At the same time, I wish it to be regarded, that my scientific opinion at present must be taken as the first stage of the inquiry as to remedial measures, and that when more knowledge as to the life history of the *Hemileia vastatrix* has been obtained, the chemical precautions and treatment may require to be modified, extended, or directed into new channels. That further progress in the chemical part of the investigation may be anticipated is no more a reason why the chemical bearings of the question may not be discussed now in the light we at present possess, than that the botanical aspects of the question should be delayed until the full physiological and pathological history of the disease should be ready to be written. In either department, a partial contribution may be of great value in indicating the knowledge of the time and the steps which may be taken in the future of the inquiry.

There can be no doubt that the fungoid organism known as the *Hemileia vastatrix* attacks the coffee plant from without; that finding its way into the leaves, it developes there a filamentous, tubular, and branched mycelium which ramifies through the passages between the leaf cells; that thereafter the branched tubular filaments are protruded through the stomata or epidermal outlets of the leaves, and that finally deep yellow or orange coloured spores or *granules* are developed in clusters in the leaves and produce the yellow granular powder popularly know as "rust." The practical effect of the disease is that the plant is called upon to elaborate nutriment in the sap of the leaf for the growth of the disease, over and above its ordinary work of providing for the sustenance of the coffee plant itself; that the life sap is sucked out of the leaf by the fungus; that the leaf becomes sapless, thin, and emaciated, and prematurely fades, dies, and drops off the tree; and that the coffee plant thus bereft of its natural nourishers and supporters—the leaves—becomes weakened, loses vitality, and fails to bring to maturity or ripen a great part of its seed.

The remedial measures which may be followed for the abatement and probable extirpation of the disease, must, in my opinion, be directed to two main channels:—First, the more thorough sustenance of the coffee plant by the liberal use of fertilising agents, and, second, the destruction of the diseased leaves and spores, as well as the pruning of the trees, by the employment of chemical agents.

The necessity for the first mode of treatment, *viz.*, the more thorough sustenance of the coffee plant itself, may be observed in various ways. The average quality of the soil in Ceylon exhibits rather a deficiency in fertilising ingredients, and comparatively little attention has yet been directed to the systematic use of manurial substances, not only to keep up the loss of fertilising power abstracted each year by the coffee plant, but to supply what the soil has not naturally been provided with, or may have lost during previous years of cropping. It must be remembered that the coffee tree is a greedy feeder and ought to be supplied with stimulating and invigorating food from the soil. When scantily provided with fertilising elements, the coffee plant cannot thrive well, and its vitality must be correspondingly reduced, leading to a lessening of the power to bring the blossom, fruit, and seed to maturity, and to a want of stamina to resist the encroachment of any parasitic fungoid growth such as the *Hemileia vastatrix*. There can be no doubt that, in an improverished condition, both plants and animals are less likely to throw off the influence of disease spores and germs, and, when attacked by such, to tide over and rally from the effects of the disease. I am therefore of opinion, that if greater attention were directed to enrich the soil with manurial substances, and thus put it within the reach of the coffee plants to obtain therefrom a bountiful supply of the food which ministers to its healthy sustenance and growth, the plant would naturally acquire more healthy vigour and will more successfully resist the ravages of the *Hemeleia*.

In the enrichment of the soil ordinary cattle manure will be of service where it can be obtained in quantity, but alongside of that, there should also be employed a more condensed and stimulating fertilizer, containing soluble and insoluble phosphates, ammonia and potash salts. An excellent mixture for this purpose would be made by compounding:—

$$\left.\begin{array}{l}\text{6 cwt of dissolved bones,}\\ \text{4 cwt of Peruvian guano,}\\ \text{6 cwt of kainit,}\\ \text{4 cwt of nitrate of soda.}\end{array}\right\}\text{ making one ton in all.}$$

This mixture will yield nitrogen equal to ammonia 7 per cent, soluble phosphates, 9 per cent, insoluble phosphates, 8 per cent, and potash 8 per cent. The ingredients for the above manure would require to be imported, as, though bones may be had in Ceylon, yet the acid required for their treatment would be difficult of transport, and hence the dissolved bones, which have already been treated with acid, would be more readily carried from place to place. If the whole mixture were made up in this country, the cost would be about £9 per ton, and considering that our manure manufacturers are in possession of first-class machinery for dissolving, incorporating, and disintegrating the manure, there should be no difficulty in obtaining the mixture in the best form for application to the soil.

If it be desired to compound the manurial mixture in Ceylon from materials which can be obtained there, such as nitrate of potash, finely ground bones, and pulverised oil cake, I would recommend the following proportions:—

$$\left.\begin{array}{l}\text{4 cwt of nitrate of potash}\\ \text{7 cwt of fine bone meal}\\ \text{9 cwt of pulverised cake}\end{array}\right\}\text{ making one ton in all.}$$

This manurial mixture will give about 7 per cent of nitrogen-ammonia, 20 per cent of phosphate, and 8 per cent of potash; and though not quite so active or immediate in its effects as a fertiliser as the previous mixture containing dissolved bones, yet it will be more lasting in its manurial power.

Either of the manurial mixtures should be applied to the land bearing the coffee plants at the rate of 10 cwt to the acre, and it would be beneficial to divide the manure into two parts of 5 cwt each per acre, and apply one-half in October immediately after the rains, and the remaining half in April immediately after the blossom showers. The coffee plant would thus have a more regular benefit from the manurial constituents and the excessive rain would not wash the ingredients out of the soil. At both periods of application, the manure should be incorporated with the surface soil, by hoeing, or otherwise, in order that the rootlets of the coffee tree may speedily be enriched thereby.

The second part of the inquiry, *viz.*, the chemical treatment of the diseased leaves and spores and the pruning of the trees, may be best carried out at the plants themselves; for though the removal of many of the leaves and the prunings to a short distance might enable the *mass* to be more actively got rid of by burning or the incorporation

with *much* quick lime, yet such would still leave the soil around the coffee plants impregnated with the spores or "rust" detached from the leaves, necessitating the separate treatment of the soil, and moreover would rob the soil of the benefit of the manurial ingredients obtainable from the leaves and prunings. I would, therefore, advise that the whole be dealt with at the plants themselves. The leaves and pruning can be changed from a diseased, decaying, and dangerous state to a fertilising and profitable one by the liberal use of quicklime, which will destroy the vegetable issue of the leaves, spores, &c., and yield products which will enrich and fertilise the soil. In employing lime, it should be used when freshly slaked, and before exposure to the atmosphere has enabled the carbonic acid of the air to neutralise the causticity of the lime, as, when carbonated, the lime becomes more of the nature of chalk than of hot lime, and has practically no burning or decomposing action upon the vegetable tissue. The incorporation of decaying leaves, &c., with the lime, and thereafter with the soil, will chemically destroy the vitality of the spores and mycelium of the disease, and at the same time supply fertilizing ingredients to the soil for the benefit of the coffee plants.

Whilst diseased leaves and prunings may be regarded as the more dangerous propagators of the disease, I am of opinion that the stems of the coffee trees should not be neglected. It may be a question whether the filamentous mycelium of the disease attaches itself to, or covers, the stems and branches; but considering the possibility of such being the case, and that the spores in the ground may thus affect the plants, I would advise that the stems and main branches be brushed over with either a solution of carbolic acid and water, or a solution of yellow sulphide of calcium. The carbolic acid treatment would be the more effectual, and may be carried out by mixing one part of the crude carbolic acid with nine parts of water in the cold, and thereafter the mixture may be applied with a soft brush to the stem and main branches of the coffee tree. This should be done before blossoming, and will destroy any spores or mycelium of the *Hemileia vastatrix* which may be attached to the stem or branches. At the same time, a little of the vapour of carbolic acid will be given off which will be useful in influencing any spores or germs in other parts of the tree. If the yellow sulphide of calcium is used, it should be prepared by boiling 5lbs of caustic lime and 5lbs of flowers of sulphur in 100lbs or 10 gallons of water, and allowing the whole to settle when the clear yellow sulphide of calcium can be poured off and be used in brushing over the stem and main branches. I do not regard the sulphide of calcium so good a material as the carbolic acid, either in its power of dealing with the mischief where it is applied, or in its tendency by rising in vapour to influence other parts of the plant.

When once the disease has attacked the plant, I am of opinion that the only practical process of combating the spread of the parasite would be by dusting finely divided flowers of sulphur over the leaves; but such a process would be necessarily expensive in material and in application. The burning of sulphur is not to be thought of, as the flames produced, *viz.*, the sulphurous acid gas, are very deadly to plant life, and will destroy the whole of the leaves, whether affected by disease or not.

In conclusion, I may state that I have no doubt that atmospheric influences, such as relative moisture or dryness of one season with another, or of the locality or district with another, will more or less affect the spread of, and the virulence of, the attacks of the *Hemileia vastatrix*; but I feel sure that climatic differences and variations are of secondary importance to the thorough nourishment of the coffee plants with high class fertilizing materials, combined with the chemical destruction of the diseased parts of plants with quick-lime. The enrichment of the soil will impart increased activity to the coffee tree, and will do more for stamping out the disease than any special measures for dealing directly with the parasite.—Yours sincerely

STEVENSON MACADAM, Ph. D, &c.,
Lecturer on Chemistry.

MR. SCHROTTKY'S LECTURE.

THE following is the lecture delivered at a meeting of planters and merchants at the Chamber of Commerce, Colombo, last month, by Mr. Schrottky on his new methods of coping with coffee leaf disease:—

GENTLEMEN,—It is necessary and consistent with the object of this meeting to take you back to the middle of the year 1879, and to review shortly the leading features of the campaign against *Hemeleia vastatrix*, guided, and I think, considering he was essentially a botanist, ably by Mr. D. Morris, the then Assistant Director of the local Botanical Gardens, a campaign which came to an abrupt and untimely end almost as soon as his guidance was withdrawn. As you will remember, it was directed against the destruction of the fungoid filaments which though not apparent to the naked eye, are found on the stem, branches, and leaves of the coffee tree, and which Mr. Morris believed to form the first cycle of the generations of this fungus. The first phase of the disease as known to the planters is the apperance on the coffee leaf of palish discolourations in, to the eye generally, well defined, more or less circular spots and patches indicating where the mycelium of the fungus is feeding in the intercellular tissue of the leaf. Under ordinary circumstances, these disease spots produce, within ten days of their first distinct appearance, orange-coloured papillate, or more properly called *uredo-spores*. The difficulty that was experienced in destroying the fungus, once it had entered into the tissue of the leaf made Mr. Morris's discovery (for such it was then believed to be) of the utmost importance. The tender and delicate filaments which he directly connected with the pin spots could of course, easily be dealt with. It introduced an entirely new phase of the subject of how to battle against the fungus and the bearings he had were fully and generally understood. I directed at the time the chief agricultural paper of India and, I threw whatever weight my opinion could give unreservedly into the scale, in favour of Mr. Morris's proposed treatment by the application of sulphur. And how could one do otherwise? In January 1879, Mr. Morris published his life history of the *Hemileia*, detailing the connection between the filaments and the diseased spots; his observations were made under the superintendence of Dr. Thwaites, well versed in the use of the microscope than whom no one had better opportunities of knowing the different phases of this disease, and who as far as we know, then entirely agreed with Mr. Morris's conclusions. Authorities on mycology in Europe took no steps to point out, what they must have known then, to be a vital error in the life history of this fungus. What wonder then I say that in June 1879, we were prepared to back up Mr. Morris through thick and thin? but alas! there never was a better illustration of the saying that *hominis est errare.* The more or less accidental dipping of the filaments into the stomata of the leaf led to the error; for an error it was. The network of fungoid filaments that can be observed on the different parts of the coffee tree has no genetic connection with the fungus. No doubt Mr. Morris must take his share of the blame that can be attached to a man who makes a false discovery, but by far the greater share is borne by others, chiefly by the mycological authorities at home. Had his account of the Life History been correct, his remedy would have been the best possible. And he no doubt was greatly misled by mere appearances. For over six months extensive experiments were carried on, under his direction, by planters of considerable knowledge and experience who thought they could see a benefit from the treatment. And there doubtless must have been a benefit. It could not have been due to the destruction of the filaments by which Mr. Morris tested the success of the treatment, nor could it have been due to its effect on the spots and spores of the *Hemileia*, for as far as I can gather information, they were only injuriously affected by the sulphur and lime treatment, when it was overdone, and then the leaf was killed as well.

But there can be no doubt that the treatment resulted in the death of millions of the more delicate *Teleuto* and *Aecidium* spores and their structures, which with the *uredo-spores* or orange rust, form the cycle of generations of this fungus as well as of all others belonging to the same family. And to this effect may reasonably be attributed the benefit which was observed on several estates. As after events showed there was an element of danger in the sulphur and lime treatment, which did much to create what was almost a panic and to stop all further experiments. Some months after sulphuring a certain field of coffee, this very field had an attack of leaf disease worse than the surrounding untreated fields. I think this can be accounted for. The sulphurous acid gas generated by the application, passes very quickly into a higher state of oxidation and becomes then the familiar sulphuric acid. The coffee plant would become charged with a certain excess of sulphuric acid, giving probably a slight sour tendency to the sap. Some observations that were made immediately after sulphur treatment add force to this. It was found that the blossom set, and fruit ripened, in a greater ratio on the treated than on the untreated area. Now some experiments have been made to show the influence of the different inorganic elements of plant food upon the various phases of vegetable life, and it was found that in the absence of sulphuric acid, plants can grow normal and upright, but they won't fruit. The analogy will at once strike you. The sulphuric acid, resulting from the treatment, aided in the setting the blossom and the ripening of fruit, but it must have imparted a sour tendency to the sap, however slight, that may have been. And that was evidently sufficient to establish *more congenial* conditions for the germination and development of the fungus, in that particular field, than the fungus found outside of it. For most fungoid growth delight in sourness. Now I don't think there can be any doubt that Mr Morris would have found out all these weak points of the treatment, had he remained, and the failure might have served as a great stimulus to new exertions; and he said distinctly that an appreciable benefit would only result, if large areas were operated upon, and infection from without carefully guarded against. I am going into all these details, not merely because I, in common with others, have supported Mr. Morris at the time, and want to justify myself, but because these details are not out of place, and are closely connected with my experiments, as you will presently see.

Mr. Morris closed his experiments in July 1879, and in his final report to Government dated the 9th of that month, he says: "When the disease has entered the leaves and is *feeding* on their tissues, there is no specific known which can effectually kill it without at the same time destroying the leaves themselves," and continues to the effect that he therefore attacked the delicate filaments which he believed to be the outward and first stage in the life history of *Hemileia vastatrix*, and he gives proof that the task he was set to had been accomplished by the sulphur treatment. You will see presently the vital difference between Mr. Morris's experiment and my own.

When I settled down at Dotel Oya with the determination to see whether really no specific could be found against this disease, I soon recognised that unless something could be found that accomplished what Mr. Morris said he could not do, *viz.*, kill the fungus *after* it had entered the intercellular tissue of the coffee leaves without destroying the leaves themselves; I repeat, unless this could be accomplished I recognized that it would be useless at the present stage of the disease and its universal diffusion, to battle against it in any other form.

What makes this fungus so formidable and so injurious in the form it appears on the coffee leaf, *is the fact* that the orange spores (the *uredo-spores*) are capable of reproducing themselves without the necessity of passing through the cycle of generations, which is carried on by the *Teleuto-spore* (produced by the same mycelium which previously bears the *Uredo-spores*.) That is to say, each rust-patch is capable of reproducing itself indefinitely by the constant germination and reproduction of the *Uredo-spores*, just as if the eggs of the *Lepidoptera* produced two kinds of caterpillars, one kind of which could constantly and in the short period of a few days, reproduce itself without having to go through the tedious cycle of chrysalis, butterfly, and egg, again, which cycle is carried on by the other kind. You can well imagine, what a pest such a caterpillar would become, if not stamped out in time. But this peculiarity is exactly what makes *Hemileia vastatrix* so formidable. But for the *uredo-spore*, the coffee planter could laugh at the *Teleuto-spore*, the *Aecidia*, *Spermagoria* and other structures forming the ordinary cycle of this kind of fungus.

It was therefore the destruction of that form of the fungus which bears the Uredo-spore to which I devoted my attention, or in other words, the destruction of the so-called pin-spot, If I could, I argued, destroy these pin-spots, without destroying the leaf, or prevent them from fruiting, there would be thought a 'chance' of battling with it successfully. Just as you can argue that if you can prevent an annual weed from seeding a hundred fold, you destroy, by so much, the chance of it troubling you again.

Now we come to the point of this meeting. How far have my experiments resulted successfully in destroying the disease spots and preventing them from fruiting?

Let us turn to the experiments at Dotel Oya carried on under the superintendence of Mr. James Blackett. I may state here that I went to Dotel Oya, so to speak, empty-handed. I did not know whether it would be possible to find a specific, and my hope was so little, that with the exception, of Mr. Blackett, only Messrs. W. C. Leechman and J. Ferguson knew that I was going up for the purpose of experiments, nor would I consent to have it made public in any way, so improbable did I deem it, that I should succeed where so many other and better men had failed. I had no predi-

lection for any particular chemical, or particular mode of applying it, but I was prepared and took with me the means so as to leave nothing that had the 'slightest' chance of proving a cheap specific, untried.

All sorts of 'topical' application were tried, to see how far the disease could externally be dealt with, and two chemicals sulphate of soda and carbolic acid, applied to the leaves in diluted solutions as a spray shewed a fair degree of success, 50 to 60 per cent of the pin-spots and spores however escaped apparently scot-free, and this would have been quite sufficient to carry on the disease.

Experiments were likewise made, calculated to create artificially, differences of condition of the sap of the coffee tree by the diffusion through their system of different chemicals suited for the purpose. Repeated trials had conclusively proved that this could not be done through the medium of the rootlets, the peculiar food-selective properties of which completely defeated the attempt to physic the trees through the soil, and I adopt the efore a novel plan of inducing absorption of different substances in the sap of the plant through the cambium of the stem, by a method which I have called "Inoculation" being satisfied that a certain absorption did take place in all but very thickly barked trees.

I was led to this, believing that a peculiar condition of the coffee tree is necessary, in addition to certain climatic circumstances, to fully develope *Hemileia vastatrix* in its last cycle. Where this condition is absent, the disease seems not to be able to get any permanent hold of the tree which generally succeeds after a little struggle in shaking it off. This opinion is strengthened by the well-known fact that not only districts, but fields, and individual trees remain comparatively unaffected amidst the most virulent ravages of the pest.

Eight different chemicals were tried and their absorption into the cambium of the stem assured by the means referred to. We adopted a basis of comparison by selecting and marking a few leaves of each trees, which showed distinctly the presence of the fungus in the pin-spot-stage, as well as defined diseased patches, but on which no 'rust' or orange spores had as yet been formed or were externally visible. We had eight different batches of trees, each batch inoculated with a certain chemical, and as I said a few leaves of each tree were marked, that showed the disease in well defined and healthy pin-spots, and there was also a ninth batch of trees that were not treated in any way, and the diseased leaves of which formed of course the principal basis of comparison. The marked leaves were carefully watched every day as to the advancement the disease made, and weather being favourable the orange spores gradually made their appearance on the diseased leaves of most of the batches of coffee experimented upon. The results were closed on the tenth day after treatment and examined closely by Mr. Blackett, Mr. Drummond, and myself, and we found that out of the eight experiments made, two had given peculiar and startling results. For while the disease on the marked leaves of the untreated trees had fruited to the extent of 83 per cent, and while in the case of six experiments of trees inoculated with different chemicals, they had fruited in a percentage varying from 53 to 88 per cent—the marked diseased leaves of trees, on the other hand that were inoculated by carbonate of potash and carbolic acid, shewed no such development of the fungus. Not one of the marked pin-spots had fruited if we disregard one leaf that showed on one pin-spot a few discolored and shrunken spores, and not only had these disease spores not fruited, but the spores themselves were turning brownish and seemed to be dying off. These results were startling, but they could not be mistaken.

To tell you the truth, gentlemen the results were such that neither Mr. Blacket nor I had the moral courage to publish them. The coffee planting community had almost made up its mind that nothing could be done against this pest, and we felt that, if we published these results, standing by themselves, we would only be laughed at for our pains. We therefore, decided to defer publication until support could be obtained by operations on a large scale.

Messrs. G. & W. Leechman (your thanks, gentlemen, are due to them) were public spirited enough to place at my disposal a few acres each on their estates near Kadugannawa. There the treatment was tried on a larger scale, and the results amply bore out our experiments at Dotel Oya. In Mr. Thom's report of the result of the treatment taken on the 10th day following the application you will find that, while on the treated area the disease spots of the marked leaves had fruited only to the extent of 11 per cent, and that in a sparing manner, a few isolated pale coloured spots only being visible on each of the disease spots—the disease spots on the marked leaves of the adjoining non-treated area on the countrary had not only in every case thrown out rich orange clusters of spores, but additional pin-spores and already developed disease patches were observed that were not on those leaves when we marked them. This shewed that on the non-treated area the disease had not only developed from the pin-spot stage and fruited, but had increased and spread at the ratio of nearly 300 per cent. The majority of the pin-spots on the treated area had commenced to turn brown and could be said to be dying off.

Still, this did not satisfy me. I knew scepticism to be so strong, that nothing but overwhelming evidence in favour of a specific would assure anything like attention from the coffee-planter. We repeated, therefore, the experiments at Moragalla, at Fairyland, at Roseneath, at Pallekelly, and at Poradenia estate; in every case with the same or similar favourable results wich have been detailed in report by the superintendents of those estates. These have all been published, and I need not weary you with a recapitulation.

Now gentlemen, I claim nothing for myself. You may lay weight upon what I have said or done, or you may not, as you please, but, gentlemen, I claim respect for the reports of the Superintendents of these estates. They are the affidavits of men, good and true, who have taken trouble to forther a good cause and who put down, not what they thought, 'but, what they saw.' The evidence I have laid before you and the public in these reports consists of facts, not opinions.

It may not be unnecessary to specially draw your attention to the experiments at Roseneath and Fairyland. Messrs. Dewar and Pyper are planters of experience whom, I think, it would be difficult to induce to put their names to any statement of what they saw, if they did not see it. Mr. Ward was present the day the experiment was instituted, and was shown the basis of comparisons we would judge results by. He was asked if he had any other way to propose by which results could be judged, which I would gladly have adopted in perference to mine. But he was understood to say that he thought the test was a pretty fair one. The results were examined at Fairyland by Dr. Thwaites, Messrs. Dewar, Pyper, and Anderson. Every marked leaf was handed to Dr. Thwaites and Mr Pyper, I believe, put down only what Dr. Thwaites said. Let me read you the result as reported by Messrs. Dewar and Pyper, of the experimental Fairyland estate:—

"In no single instance" had any of the pin-spots on the treated area thrown out any spores. The pin-spots themselves had turned brown and were pronounced to have been injuriously eated upon,

"The pin-spots on the marked leaves on the untreated area, on the country, had 'in nearly every case' thrown out spores, a few only had not done so."

What need I say more? Planters that are not satisfied with such evidence, will never be satisfied. Attempts have been made to discredit the results by sundry suggestions, and lastly statements have been made that have more or less reached me. It has been said that absorption through the cambium was against the laws of vegetable physiology. I said it was not and have thrown down my gauntlet. It has not been taken up yet. Another said whether in concord or discord with established laws, he did not believe that chemicals could get into the cambium of a living tree. I shall be most happy to convince that gentleman by what he can see with his own eyes.

I have heard of two gentlemen who inspected the *modus operandi* of the inoculation and the results. So well were they satisfied the chemical I employ gets into the cambium, that two days afterwards it was currently reported that three acres of inoculated coffee were breathing their last. And then we have seen opinions published something like this "I had a little faith in Mr. Schrottky's process, but I thought he did it very differently. His *modus operandi* does not fall in with my idea, I have lost therefore all faith. How some of the witnesses could have seen the results they reported, goodness only knows."

I think we may disregard all those opinions. They cannot shake or alter the results which have been seen and attested.

I think, gentlemen, we may say now, on the basis of these results, that we have found a specific which will still the fungus in the pin-spot stage and prevent it from fruiting, a specific that will kill the fungus without destroying the leaves themselves. But that is not enough. The most important work has still to be done, namely to show that the riddance of this pest to a greater, or less extent, will benefit the pocket of the planter.

This has still to be shown. Both "inoculation" and "vaporisation" have given satisfactory results. The latter has much to recommend it; it can be repeated as often as necessary and at a moderate cost. Three applications which I have every reason to believe will carry on an estate through the period of an attack of the disease, will, in the aggregate, in labor and chemicals, not cost more than Rs. 10 or 12. It is quite possible that the 'inoculation' may benefit the plant to such an extent that the greater cost of it would not stand in its way, but some time must elapse before I can decide upon this point.

The practical issues involved are illustrated by a simple *simile* or example.

What is commonly called 'White Weed' is I believe a pernicious plant difficult to eradicate, once it has got hold of a coffee estate.

Imagine now an estate that is simply covered with it to the injury of the bearing qualities of the coffee, and that up to this time you had known no method or means of pulling it out. An economical method is shown to you now, and means are given to enable you to pull the weed out, and you are recommended to do so before it had time to fruit. You try this method and means say over a few acres. Yes, sure enough; you find it can be done. You stifle the weed you find in that area and prevent it from seeding. Will you be surprised now if you look at the same area again in a month's time or so and find the weed again there, almost as bad as ever? Believe me, gentlemen, the coffee leaf-disease is nothing but a weed which you have allowed to grow unchecked over your estates. It pays you to keep your estates clean of the ordinary weeds, and it will likewise pay you to keep your estate clean of this weed. You have now the means to do so.

But you must be prepared for most disheartening work. As fast as the fungus will be killed, so fast almost will it re-appear, but assuredly there will and must come a time when the planter will be able to sit down draw a deep breath of relief and say—"the battle is mine."

COFFEE PLANTING IN SARAWAK.

THE following paragraphs are taken from a recent issue of the *Sarawak Gazette*:—

It is with great interest that the coffee planting commenced only within the last two years in Johore, must be watched by all countries in the vicinity of Singapore. Sarawak is in the same latitude as Johore, and the rainfall cannot be very different. Perhaps in the neighbourhood of Kuching it is somewhat more abundant, but in the other parts of the territory it is probable less. The height of mountains are about the same, though in this country there are few which reached 5,000 feet, a height which the lands in Johore equal. Temperature and rainfall being the same, it is natural to suppose that if coffee is a success in Johore, it will also be a success in Sarawak, and also in North Borneo and other parts. The only trial of a coffee plantation of any size made in Sarawak was on the side of a mountain at about 800 feet elevation (the peak of the mountain being 3,000 feet) in light friable soil of sandstone formation. There were 140,000 plants put in from the best Ceylon seed, sown in nurseries on the mountain, some in shade and some in the open, and some in partial shade. The young plants were especially fine and strong, and many threw out blossom, and some fruited at 18 months' growth. This of course gave good promise, but when they had arrived at 3 years old and a plentiful crop was expected, it was found that although the trees seemed sound enough and were continually throwing out blossom, that there was little or no result to speak of, the trees after a short time became weakened. Some were pruned by an experienced Coffee Planter in Ceylon, but after expectation for some years and a large outlay, the garden was abandoned as a complete failure. There may of course have been mistakes committed in the choice of a site for the culture or in the method of treatment, though the garden had the benefit of superintendence from experienced planters. The downfall of rain and want of more defined seasons seemed the great drawbacks.

Coffee planting in Java is done principally by natives and forms part of the Government revenue, but so far as we have heard Europeans have not embarked on this culture as they have in sugar and other plantations. In the other islands in the Archipelago where it is grown, it is mostly native coffee. The success of this will much depend on the decision as to whether under altered circumstances it is advisable to adopt the Ceylon system of pruning. Again we repeat the plantations in Johore will form a valuable precedent for the guidance of future capitalists who wish to embark in coffee plantations in these latitudes.

CINCHONA.

THE Java process of "shaving" the bark has been tried on a number of *succirubra* trees on the Darjeeling Tea and Cinchona Estate. So far, the trees do not appear to have suffered in the least from being stripped off their bark.

WE learn that Mr. Gammie of the Government Gardens at Sikhim has so successfully devoloped his mode of manufacturing "sulphate of quinine" from the ordinary red and crown barks, that the Government of India contemplate the erection of a laboratory in which a large supply of his preparation can be turned out.

A CROP of 150,000lbs of dry bark has already been despatched to the Secretary of State from the Government Cinchona Plantations on the Neilgherries. A further shipment of about 50,000lbs is expected to be made shortly. The current season's crops was estimated at 180,000lbs, and will very likely be exceeded by 20,000lbs. At six rupees per pound, which is the average price realized, the season's crops will clear a sum of Rs. 1,200,000.

THE importance of the supply of Peruvian Bark now obtainable from India is shown in the following figures :—

SUPPLY OF PERUVIAN BARK TO THE LONDON MARKET.

		1879 80. lbs.
Colombia	...	6,002,330
India and Ceylon	...	1,172,060
South America (except Colombia) ...	...	959,030
Jamaica, about	...	21,740
Besides Java, for the Amsterdam market	...	70 088

Few important industries have been built up with such rapidity as this. The results of the sales of bark from the Government Cinchona Plantations on the Nilgiri Hills have been so successful that by " 1880 the whole capital account had been paid off with interest, and the plantations began to yield a clear annual profit."

THE necessary plant for manufacturing quinine is, says the *Ceylon Observer*, of the most inexpensive character—

All that is required being wooden tubs, calico filters, acid and caustic soda. The extent of the outturn of febrifuge since the work was begun in 1875—has been 1,940 lbs in 1876,—3,750 lbs in 1877—5,612lbs in 1878, and 7,007 lbs in the following year. The cost of production is given as three rupees per pound, and the prime cost of the bark and interest on capital is five pence per pound, consequently the cost of raw material sufficient to produce one pound of the febrifuge is twelve shillings and five pence, and adding manufacturing charges, we have eighteen shillings and five pence as the total cost per pound, or not much more than a shilling an ounce. Assuming these calculations to be correct, the Indian Government could make good profit by selling their febrifuge at a rupee an ounce. In the event of a profit being allowed private growers who may in time to come find it to their interest to sell on the spot at a shilling a pound, the febrifuge could be produced so as to a yield a fair profit if sold at two shilling and six pence an ounce, a figure which would undoubtedly command a large demand for it, in Ceylon alone. The yearly consumption of quinine in the Government hospitals and dispensaries must be considerable, and no doubt if a febrifuge equally efficacious could be had on the spot for two shillings and sixpence, the consumption would be much greater.

JAMAICA *vs.* INDIA.

THAT rising industry of Southern India, the cultivation of cinchona, is threatened, it appears, by a formidable rival. A few years ago it entered the mind of the Jamaica Government that some good might come of experimenting with the plant at various elevations. Seedlings were accordingly obtained from South America, and the Director of public garden and plantations took the work in hand with that zeal and energy which go so far to insure success. And unquestionable success has Mr. Morris achieved, although the industry still is, of course, merely in the embryonic stage. According to the showing of an official report in the *Government Gazette*, Jamaica exported last year close on 80,000lbs weight of bark, which realised nearly £5,500 in England, when put up to auction. But what was even more satisfactory was the fact that the Jamaica produce commanded higher prices than any of its older rivals at the last sale in the year. The greater portion of the South American parcels were bought in, because the prices on offer would not have allowed any profit. The highest price of those sold was 4s. *2d*. per lb for good Carthagena bark, a description which has heretofore received great favour. Passing on to the Ceylon samples, we find it recorded that "Fine Quill" bark from that colony commanded 7s. 4d. per lb, and " Root Bark" *6s. 4d*., against *7s.* 11*d*. and *6s.* 10*d*. respectively, for the same qualities from Jamaica. These quotations were for what is called " Crown or Grey Bark," but not less advantage rested with Jamaica in "Red Bark," and "Twig" sorts. It thus appears that the West Indies have already more than equalled the East in the quality of their cinchona, both going far ahead of South America, except in comparison with certain special brands of exceptional excellence. But it must not be imagined that the whole of Jamaica could be turned to this purpose. Cinchona will not grow there at all at a less elevation than 2,500 feet about sea-level, and from that up to 4,000 feet, only ' Red Bark" plants will thrive. After the latter height is passed, this variety at once begins to languish, but, odd to say, " Crown Bark" then commences to flourish, and continues to do so up to the highest altitude of the Blue Mountain range. The question is, therefore, how much land of the required sort will be found available? Southern India will not be gratified to learn that, in the opinion of Mr. Morris, " vast tracts of land lying hitherto uncultivated on the northern slopes of the Blue Mountain range will ultimately prove suitable for cinchona." Nor is this merely theory, the conditions of the area here mentioned, seem to be such as would render failure well nigh impossible. A rich, friable soil, a sloping situation so as to insure natural drainage below ground, and a miost, equable temperature are the chief requirements of the cinchona planter, and all of these exist in perfection on the beautiful Blue Mountain range. Good drainge is all-important, it seems; the moment the roots of the plant strike down into a sub-soil, which has a habit of collecting moisture, it surely sickens and withers away. This peculiarity is found in the whole cinchona tribe, and any planter who does not make his account with it, will be pretty sure to have it brought to his knowledge in an unpleasant fashion. But when the site selected for a plantation is on a natural slope, the sub-soil is almost invariable well drained, and this is why cinchona is generally cultivated on ground of that description. Have we none of it in the Himalayas? Enough to grow cinchona, if good drainage were the only requirement for success, to supply the whole world. But it would be only here and there, we fear, that the "rich friable soil," and the "moist, equable temperature" would also be found. Our mountain ranges, however, are so vast, both in superficies and in altitude, that one would be disposed to credit them with the possession, in one part or another of all qualities necessary for the production of good cinchona. It might be as well to prosecute inqury on this head. Few who are personally acquainted with the Himalayas will be found to affirm that we have as yet even tapped their potentialities of wealth. They form a sealed book, which British enterprise will assuredly open sooner or later, and perhaps one of the first pages will be the that to which beautiful but " played out" Jamaica, directs our attention. With every sort of climate, soil, and situation, with plenty of labour, either on the spot or close at hand, with ample facilities for making decent roads, the vast mountain ranges of North-Western India will some day prove a veritable Tom Tiddler's land, greatly to the enrichment of our home country. Perhaps the time has not yet arrived for promoting a " Himalaya Developement Company," on the London Stock Exchange, although far more speculative enterprises are now greatly in favour with the confiding British public. But if the Government out here were to do what Lord Lytton did for the Wynaad, by setting on foot official inquiry into the concealed resources of the Himalayas, and then publishing the results in the *Gazette*, we feel assured the way would be at once made smooth for the introduction of a flood of British capital and enterprise into our magnificent mountains—*Civil and Military Gazette.*

GROWTH OF THE CINCHONA INDUSTRY IN INDIA.

THIS new trade is of great promise, both as regards export and the benefits to the people which the use of the bark produced in India is already causing. The exports of the bark for the past four years are as follows :—

		Quantity. lb.		Value. £.
1875-76	..	26,992	...	2,570
1876-77	...	72,452	...	6,413
1877-78	...	286,944	...	39,635
1878-79	...	227,179	...	28,196
1879-80	...	459,286	...	66,071

The cinchona tree was introduced a good many years ago from Peru, and its cultivation in the Nilgiris and near Darjeeling was persevered in until it has now taken firm root and become thoroughly established. In the Government cinchona plantations near Darjeeling in 1879, there were 2,174 acres under cultivation, containing a total number of nearly five million plants, cuttings, and seedlings, of which upwards of four millions were permanent plants, a great proportion of them large trees. In the Nilgiri plantations there were nearly 1,100,000 plants, and in Burmah close on 100,000 more. The bark produced on the Darjeeling plantation is converted on the into into an alkaloid, possessing much of the efficacy of sulphate of quinine, which is sold at the rate of Re. 20 the pound : the price of imported quinine averaging Rs. 90, or four and-a-half times the price of the alkaloid. The plantations have produced about 1½ million pounds of bark since their commencement ; and last year 9,424 pounds of alkaloid were manufactured for issue to Government hospitals and dispensaries, and for sale to the public, by whom it is eagerly bought. The factory is now able to produce sulphate of quinine, and proposals for its manufacture are at present under consideration. This cheap and efficient substitute for the costly imported quinine has already proved of the greatest benefit, especially in the epidemic of fever, which in the autumn of 1879, swept over the greater part of the North-Western Provinces and Punjab, prostrating for months a very large percentage of the population, and causing lamentable mortality. The variety of cinchona chiefly grown at Darjeeling is C. *succirubra*; but efforts are now being concentrated on the propagation of C. *calisaya*, a more valuable kind producing a larger proportion of alkaloid.

In the Nilgiri plantations the manufacture of the bark has been discontinued for the present, and it is exported for sale in England. The example of Government was followed by private individuals, both in Darjeeling and in the Nilgiris. In Darjeeling there were 1,800 acres under private cultivation at the end of 1879, with about 1½ million plants. All the bark produced on the private plantations is sent to England for sale.—*J. E. O'Conor.*

SERICULTURE.

SILK IN BENGAL.

UNDER the title of "A few words on the present state and future prospects of sericulture in Bengal," Mr. J. A. H. Louis has published an interesting work which is calculated to revive the flagging interest in the silk-trade of this country. The steady decline of the silk manufacture for several years past has been the cause of serious loss to those classes of the rural population who had previously found a source of remunerative employment in that industry. Considering the growing demand for silk quite out of proportion to the available supply, we think that no effort should be spared to set on foot again an industry, which acquired for Bengal a celebrity, forming a no inconsiderable attraction to foreign commerce in the years, before it became the "apple of discord" to the commercial nations of Europe. In a statement of the quantity and value of silk exported from Bengal during the years 1870-1878, Mr. Louis gives the following statistics of raw silk:—

	lbs.	Value £	Value per lb. Shillings.
1870	2,591,701	1,561,512	12·04
1871	2,280,159	1,351,846	11·85
1872	1,987,867	1,130,709	11·37
1873	2,373,939	1,305,487	10·99
1874	2,392,230	1,225,599	10·25
1875	1,730,769	796,676	9·21
1876	1,417,313	452,370	6·38
1877	1,568,490	855,748	10 65
1878	1,658,005	750,439	9·06

It will be seen that the exports have fallen off during these nine years by about 35 per cent, while their total value has diminished to less than a half—their comparative value in the two years 1870 and 1878 being in the proportion of 12·04 and 9·06, or a difference of nearly 25 per cent. It has been generally supposed that, in consequence of the unremunorativeness of the industry, the silk turned out by the Indian cultivator is of an inferior quality. Such may, to some extent, be the case; but Mr. Louis is of a different opinion and holds that the chief cause is to be traced to the decline in the quality of the worms. It is believed that they are now liable to a disease which injuriously affects the value of their produce. The worms die out in immense numbers, and such as survive only spin an inferior silk, and reproduce a sickly breed. This disease is attributed to the enervating nature of the climate which is almost irremediable. Mr. Louis strongly recommends the continual introduction of silk worms' eggs from such countries as are free from diseases, and quotes the experience of France and Italy in proof that the most scientifically contrived remedies will be but partially successful. In France experiments, with a view to the prevention and cure of the diseases of the silkworm have been tried with but a certain amount of success; but Italy adopted the simple remedy of importing eggs from Japan annually. The produce of silk in Italy, which in 1850 amounted to 3,460,000 kilos., had fallen in 1864 to 1½ million kilos. By the introduction of a new and healthy variety of eggs, the manufacture has been restored, and during the last eight years the average produce has been close on 3½ million kilos. The same remedy is recommended for Bengal, and in view of the peculiar helplessness of the Indian silk maker, the establishment of Government nurseries is strongly advocated, as well as the introduction of stores on hill stations for the preservation of the eggs until the proper season for hatching arrives. If these simple recommendations are attended to, it is more than probable that a flourishing and profitable industry will soon be firmly re-established not only in Bengal, but in other parts of India, where the climatic conditions and the tastes of the people have made sericulture a local industry. The rearing of silk-worms and the manufacturing of silk are peculiarly adapted to the habits of the natives of India and in the absence of private enterprise, the Government might well help in reviving an industry which under favorable conditions might contribute to the material welfare of the masses. In the Dehra Doon an English firm has already made arrangements for developing the indigenous industry, and it is probable that they will reap the fruit of their enterprise.

THE NATIVE SILKS OF ASSAM.

THE native silks of Assam, known as "Eria" and "Muga," are the produce respectively of "Attacus Ricini" and "Antheraea Assama," and "Antheraea Mesankooria."

The *Eria* worm is so called from the local name of the castor-oil plant (*Ricinus communis*), on which it is almost exclusively fed. It is reared entirely indoors. The duration of its life varies with the season; with the summer, it is shorter, and the product is both better and more abundant. At this season, 20 to 24 days elapse from the date of its birth to the time when it begins its cocoon, 15 days later the moth is produced, in three days the eggs are laid, and in five more they are hatched, making the total duration of a breed 43 days. In winter, his life extends to nearly two months. Seven breeds are reckoned upon annually. For breeding, the natives select cocoons from among those which begin to be formed in the largest number on the same day. Those containing males are recognised by more pointed ends. On the second or third day after the cocoons have began to be formed, they are put into a closed basket, and hung up in the house, out of reach of vermin and insects. Twenty-four hours after the moths have been produced, the females are tied to long reeds or canes, 20 to 25 to each, and these are suspended in the house. The eggs laid during the first three days alone are kept; they are tied up in a piece of cloth, and hung from the roof till a few begin to hatch; these eggs are white, and resemble turnip-seed in size. When a few of the worms are hatched, the cloths are put on small bamboo platters, and here they are fed with tender leaves. After the second moulting, the worms are removed to feed on bunches of leaves, suspended a little above the ground, and a mat is spread beneath to catch those which fall. When they have ceased feeding, they are placed in baskets filled with dry leaves, amongst which they form their cocoons. In four days, the latter are complete. A selection having been made for the next breed, the remainder are exposed to the sun for two to three days, to destroy the vitality of the chrysalis. The cocoons are next generally put into water containing potash (wood-ashes), over a slow fire; when removed, the water is gently squeezed out. At other times, they are massed together for some days with "amrita" (? *Carica papaya*), or "madhu" fruit. The object is the same in either case, *viz.*, to facilitate the drawing of the silk. The cocoons thus treated are taken one by one, and the silk is placed within the thumb of the left hand, whilst the right is employed in drawing out the silk. Any inequalities that may exist are reduced by rubbing them down between the thumb and finger; the same process serves for joining on new cocoons. The thread is allowed to accumulate in quantities of about half-a-pound; these are afterwards exposed to the sun, or placed near a fire, till dry, when they are wound up into skeins. The silk is then ready for the weaver. It is the coarser of the two kinds, and none of it ever finds its way into Bengal.

The *Muga* moth is found wild in the jungle, but all the silk produced by it is from domesticated worms. They are reared on trees in the open air. There are generally five breeds in a year, *viz.*, January to February, May to June, July to August, September to October, and November. The first and last yield the best crops as regards both quantity and quality. Constant watching of the trees is necessary. By day, crows and other birds pounce upon the worms and devour them. By night, bats, owls, and rats are very destructive. Numbers of the caterpillars are destroyed in the more advanced stages by the sting of wasps, and by the ichneumon insect, which deposits its eggs in the bodies of the worms. The latter thrive best in dry weather, but a very hot sunny day at the moulting time proves fatal to many. Indeed, at this period, rain is considered very favourable and even thunderstorms are not injurious, as they are to the mulberry worm. Continual heavy rains do mischief by sweeping the worms off the trees, but showers, however violent, cause no great damage, the worms generally taking shelter under the leaves with perfect safety. During moulting, the worms remain on the branches, but when about beginning to spin, they come down the trunk. Bunches of fresh plaintain leaves are tied round the trunks at some height from the ground, in order to arrest their progress. The worms are then collected in baskets which are put under bunches of dry leaves suspended from the roof of the house. They crawl up into these, and there form their cocoons. The total duration of a breed varies from 60 to 70 days; the period is thus divided:—4 moultings, 20 days; from fourth moulting to beginning of cocoon, 10 days; in the cocoon, 20 days; as a moth, 6 days; hatching of the eggs, 10 days; total 66 days. Chrysalis not being easily killed by exposure to the sun, a number of cocoons are placed upon bamboo stages, and covered with leaves, whilst a quantity of dry grass is ignited below them, and in a short time destroys them. The cocoons are then boiled for about an hour in water containing potash (the ashes of mustard and other plants). When taken out, they are laid between folds of cloth. The floss is removed by hand, and the cocoons are thrown into hot water. The instrument used for winding off the silk is the roughest imaginable. A thick bamboo, about 3 ft. long, is split in two, and the pieces are driven equally into the ground about 2 ft. apart, over the interior projection of one of the knots is laid a stick, to which is fixed, a little on one side, a round piece of plank, about 1 ft. in diameter. The rotary motion is given by jerking this axle, on which the thread rolls itself. In front of the vessel holding the cocoons, a stick is placed horizontally for the thread to travel upon. Two persons are employed—one attends to the cocoons; the other jerks the axle with the right hand, and with the same hand directs the thread up the left forearm, so that it is twisted in coming down again towards the hand, while the left hand conducts the thread over the axle. The Assamese consider it a good annual return if an acre of trees support 50,000 cocoons, yielding upwards of 24lbs of silk. It must be very profitable, as 1,000 cocoons are reckoned to afford 6 to 8½ oz of silk thread, selling at 10*s*. to 12*s*. a pound. The labour and expense of maintaining a plantation of the trees is very trifling.

Two kinds of silk are distinguished by the natives as the production of the *Muga* worm—*Muja* and *Mujankuri*,—their difference being attributed to the trees on which the worms are fed; but naturalists have determined a specific difference in the worms themselves, calling the former "Antheraea Assama," and the latter "Antheraea Mezankooria." The *muga* worms feed chiefly on the "Sum" tree "(? Artocarpus chaplasha; Tetranthera lancielata); mujankuri, from those fed on the "Adakur" tree "Tetranthera quadrifolia". The latter is whiter and better than the former. Some of the silk thread produced in Sibsagar sells for as much as 35*s* a pound. Lakhimpur in 1871, exported 11¼ tons of *Muga* silk thread, valued at £6,099.

The reader may refer to the *Journal of the Society of Arts*, May 9th 1879, for further information on Indian wild silks.—J. G. WARNFORD LOCK.

TOBACCO.

WE wonder that no one in Arakan has been enterprising enough to try tobacco cultivation there. From all accounts, Arakan tobacco only needs proper curing to be equal to Manilla. Moreover, the returns from such an investment are likely to be much more quickly obtained than from coffee estates, which some people seem to be turning their attention to in Arakan.

We publish the following papers at this Office :—

THE INDIAN AGRICULTURIST.
(MONTHLY.)
Rates of Subscription, including postage.
STRICTLY IN ADVANCE.

For India	Yearly	... ...	Rs. 12 0

Manager.

THE
WEEKLY CEYLON OBSERVER.

THE best newspaper publication in the world for tropical planting intelligence and all matters affecting the statistics of production and the practical cultivation of coffee, cinchona, tea, cocoanuts, cinnamon, cacao, and other similar products. The proprietors and editors (Messrs. Ferguson) have had prolonged experience in Ceylon, as journalists, and in connection with planting. The paper is largely circulated in Ceylon, India, British Colonies, and the United Kingdom, also in Java and Brazil.

Subscription, including postage 18 rupees (£1 16s.) per annum in advance, and Advertisements at 9*d.* per line of 10 words.

Also published (annually) by Messrs. Ferguson, at their "Observer" Office, the "Ceylon Directory and Hand-book of Information," on subjects affecting tropical cultivation as well as all Ceylon matters—1,000 to 1,200 pages demy octavo, price, 8 rupees (16s.) per copy, including postage; Advertisements, Rs. 20 (£2) per page, or Rs. 12½ (£1 5s.) half page. Orders (with Bank Drafts) for all the above received at the "Observer" Office, Colombo, Ceylon; or through Messrs. Geo. Street & Co., 30, Cornhill, London, and Messrs. J. Haddon & Co., 3, Bouverie-street, Fleet-street, London.

NOTICE TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

ABOUT PAPER FIBRES.

SIR,—As Mr. Liotard's Memorandum, "Materials in India suitable for the manufacture of Paper" is the latest Text-book on this subject, therefore no doubt likely to be much referred to, it may be well to direct attention to get another class of fibres or fibrous products mentioned in several of the district reports in that publication.

At pp 5, 11, 14, and 15, the palms are specified as being useful for paper material ; their leaves, the leaf-stalks or mid-ribs, and even the coarse harsh fibre covering the fruit or nut.

Now the palms are a very large family comprising nearly 600 species, the date, the cocoa-nut, the areca-nut are named in the reports, but many other varieties abound in India, collection therefore no doubt could be made at little cost, but I have not yet seen the leaf of any palm that could be utilised for such purpose ; always be it understood fitted for English or European requirements, and the fibre therefrom producible at a cost that will allow of its competing favorably with existing material, the fact being that the leaves and leaf-stalks of nearly all the palms are hard, horny, and silicious, the ultimate fibre therefore can only be produced from them by costly treatment of high pressure boiling with strong caustic alkali together with considerable mechanical manipulation :—The yield of available fibre would be very low, and that fibre harsh, difficult to bleach and unsuitable for our English papers.

To quote a familiar example, the dwarf palm, which abounds on the Mediterranean littoral of Spain and Africa, the *Chamærops humilis*, the freight being low has been imported again and again, but found fitted only for inferior grades of paper.

The screw pine, *Pandanus utilis* or *Borassus flabelliformis* has tempted many experimentalists, probably seeing the abundant crop of leaves it produces, but these again are valueless, except perhaps for the commonest papers, the bulk of the sugar imported from the Mauritius comes in bags made from their leaves.

One reporter recommends probably the most unsuitable material of all, *viz.*, the leaves of the Prickly pear, the *Opuntia dillenii* or *O vulgaris* ; an ordinary deal plank would be more amenable for paper material, and the fibre threfrom superior and produced more cheaply.

I am tempted here to quote the remark of the celebrated D. Abernethy to his dyspeptic patient who was fond of cucumber. "Peel it carefully, slice it thin, dress it with plenty of oil, vinegar, pepper, and salt, and then—throw it out of window" so with regard to this class of fibres and their value for the purpose in view, *viz.*, paper material even after a costly system of treatment, they won't digest, that is won't sell, and I would caution intending pioneers to transmit only a few cwts for experiment before incurring much expenditure.

To sum up : What are paper-makers *régime*, is a soft, silky, cottony, or flaxy fibre capable of being finely divided, or split up, and felting well from the divisibility of its fibres when reduced to pulp by the ordinary processes of paper-making.

In point of fact, the paper-maker if he could procure them in sufficient abundance, and at reasonable cost, would infinitely prefer rags to any other material, and it is only their daily increasing cost and scarcity which has induced the use and demand for other material.

By rags I mean the cast-off, worn, or partially worn out clothing, or other fabrics made from vegetable (not animal) fibres such as cotton, flax, hemp, jute, &c., &c., and failing these, a raw or partially prepared fibre assimilating as near as may be to rags in character is the desideratum. In another letter I will endeavour to explain technically, that is practically, why rags are preferred to ordinary raw fibres unless such fibres are offered in a condition presenting similar or nearly similar characteristics.

THOS. ROUTLEDGE.

Claxheugh, Sunderland, 3rd March 1881.

THE CROTON OIL PLANT.

TO THE EDITOR.

SIR,—I see from a letter to the *Ceylon Observer* published in your issue of the 1st February, that it is actually proposed to introduce the cultivation of the croton oil plant in Ceylon.

I seize a spare moment to express a hope that no such step may be taken. I know the croton oil plant well. Two varieties of it, one of which, but I am not sure which, is the croton tiglium, grow in abundance in the Madras Presidency, where it is a noxious weed, very troublesome from its habit of sowing itself widely and from the difficulty of eradicating it. It is to some extent used as a hedge, because it grows so very freely from cuttings, but it is a very short-sighted policy to use it as such, for it never makes a good hedge, is not stiff enough to keep out trespass[illegible] nally spreads laterally till it fills the whole of the enclosure it was intended to fence; fortunately its roots do not extend deep into the ground, and it is easy to pull it up by the roots after rainfall. In the neighbourhood of Madras it is so abundant that it poisons much of the standing and running water. It is a well-known fact that water impregnated by this plant causes cattle disease, and it would probably cause diarrhœa in men. I don't think it would ever become a good shade tree even in the luxuriant climate of Ceylon. It is only an ugly, sprawling, overgrown shrub, seldom more than 7 feet high. As to the use of the product as an article of commerce, I can only hope that doctors are not going to use this deadly poison largely as a purgative. You see what Mr. Whyte says on that point. I should think no doctor would ever require to use such a dangerous and violent purgative many times in his practice.

C. D.

PLOUGHS AT THE LUCKNOW EXHIBITION.

(To the Editor of the Express.)

DEAR SIR,—On reading the article contained in your issue of the 4th February last, asking for a fair trial for my ploughs at the late exhibition, I felt myself bound to submit them to the test and sent 6 ploughs of all sizes to the committee. The first trial came off on the evening of the 9th instant, and although, I had previously suggested the watering of the ground to one of the members of the committee, the precaution was not adopted, and the result was that after two or three hours' labour the trial broke down; to the disgust of the spectators who came to see it, and caused the sarcasms, and bitter remarks of the native agriculturists who had never heard of such a proceeding—wherever I went I heard loud expressions of native opinion such as, "*Yeh hull ismeeluck nae naheen chullega*"—"*keea sookee dhurtee jotat hai?*"

This morning a second attempt was made, and the ground being previously watered everything appeared promising, but on finding that bullocks of various sizes and strength were being used for each plough, I suggested that, as the draught was an important item, the sizes and condition of the cattle might be noted in each trial. This was at once over-ruled by the two European members of the sub-committee belonging to the Agricultural Department, the two native gentlemen being simply of the *jo hookum* class, and appeared perfectly ignorant of agriculture. I then went and appealed to one of the members of the committee who very indifferently suggested that the sub-committee be left to work on their own lines. As my plough had been repeatedly tried with success against those of the chief competitors both at Calcutta and Bolundshahur, (where I am happy to say I obtained the first prize) I thought it was folly to submit my invention to the opinion of a jury who seemed to be oblivious of the *first* requisites of a plough intended for India, and was only too thankful to obtain permission to withdraw from the competition. There is no lack of ploughs in Europe and America, and it is the nature of the draught in this country which necessitates an alteration to suit the bullocks and the native habits, and I therefore cannot comprehend how this important consideration was lost sight of; and although a dynamometer was available on the spot, it was never used? The following points should in my humble opinion comprise all the conditions required of a plough to suit his country, and on these I am prepared to test my invention before a committee of *practical* agriculturists not personally interested in the matter.

1stly.—The object in view being to improve the native plough as it exists, the first point for consideration must be how far the modified implement resembles the plough in all its parts.

2ndly.—That it possesses the slightest difference in appearance to the native type, and is not an eye-sore to the ryot.

3rdly.—That it is within the power of the smallest bullocks; as it is necessary to adapt the implement to the power available in this country.

4thly.—That the ploughman can hold the stilt with one hand and reach the bullock's tail with the other. This is a most important advantage in the ryot's estimation. All double handled ploughs, and those having the stilt placed at a wide angle, must be held to labor under this disadvantage.

5thly.—That the plough is light and from its form of construction can be easily carried on the ryots, shoulders.

6thly.—That the plough is durable, and in case of accident the injured part is easily repairable by any village carpenter or blacksmith. All ploughs with any cast iron parts must be held to disqualify it on this point.

7thly.—It must do more and better work than the country plough with the same power.

8thly.—It must be cheap and within the means of the ryots, the common country plough costs from Rs. 2 to 3.

9thly.—It must be so constructed as to make a furrow of any depth or width, according to the capacity of the bullocks, and turn the sod completely over, without this qualification the plough cannot be considered an improvement on the native plough.

LUCKNOW: 11*th March* 1881.

Yours faithfully,
W. MARTIN.

COCA.

(To the Editor of the Ceylon Times.)

SIR,—While everyone who has any "go" at all is watching with interest the "many" experiments with low country products now being tried in the plains or the lower districts of Ceylon, it is a good thing to look round us and see if we cannot fall upon a new product that will suit our hills, especially as many of them look badly in want of some produce or other to cover their nakedness. Now I do not see why we in the wetter high districts (Maskeliya for instance) should not try Coca. It makes one's mouth water to read that in Peru, Coca returns 40 per cent., that it yields 800 lbs. to the acre and is worth about 40 cent. (say 10d.) a lb. on the spot, &c., &c. It is described as a shrub from four to six feet high, growing luxuriantly at 5,000 feet on the warm and humid slopes of the Andes. The leaves are used by the Peruvian and Indian as a masticatory just as beetle is used here. No less than 8,000,000 people, it is said (like so many bipedal caterpillars) daily devour the leaf. The Coca leaf is firmly believed in as the only Medicine the Peruvian Indian knows, and he pays his 5 dollars for an arroba of 25lbs. cheerfully. The sowing should be commenced in May or June when the rain are on, and the seed should be sown in a nursery carefully sheltered by a thatched roof, the seed will germinate in a fortnight and should be carefully picked out and gradually hardened by removal of the shade above the beds, and planted the following May or June into the field. The plants are said to be more susceptible of work and in the Peru Mountains they are terraced on the steeper slopes while on the plains they are planted very much on the "Montclar system" that is each plant is enclosed by a mud wall. At eighteen months the plants will yield their first harvest, with plenty of rain a flush should be expected every forty days. The green leaves, called mata, are dried in the sun and packed in bags of 50 lbs. each. To give some idea of the large trade in Coca, this traffic yielded as long ago as 1795 £528,300. Seed can be purchased in Buenos Ayres.

PIONEER.

WELL IRRIGATION IN GUZERAT.

(To the Editor of the Times of India.)

SIR,—The rainfall (28 in. 70 cts.) during the past season was perhaps, all that could be desired by the uncomplaining meekspirted cultivators of the Duskroce pergunnah in this collectorate. The harvest was, comparatively speaking a good one, and grain of every description and forage are very cheap. The agriculturist has, therefore, according to the vague notions of unreasonable thinkers and random writers, nothing whatever to complain about. Recent diligent inquiries made by me during my peregrinations convince me, and compel me to say, that preparations are not being made to any noticeable or remarkable extent, at wells in the boundaries of villages in the neighbourhood of Ahmedabad to sow and raise a second crop by irrigation. From the inquiries made by order of Government some time ago, it was painfully apparent that out of 873,804 acres of land under tillage, only 14,047 were twice cropped. Another lamentable fact that appears to me to demand the serious and timely consideration of Government is this. Many of the bullocks of different sizes that have hitherto been used from June to November to plough, sow, and harrow land, and to thresh corn &c, with grain and forage

that can be ill-spread, now being taken as fast as possible by the poverty-striken ryots to the city into a falling market, and disposed of at ruinously low prices, to enable them to meet the first instalment of the revenue demand (due on the 20th instant), and the claims of inexorable usurers. In your issue of the 11th idem, you obliged me with space for my letter on "Well Irrigation in Gujerat." The question that now stares every deep-thinking observer in the face is this: Why are the *very few wells* that are in existence under our enlightened rule permitted to remain unused, when paying crops may be raised, cattle retained and fed, and general improvement effected in the present wretched condition of the agricultural classes? The reply is unquestionably simple enough, and is contained in part of a leading articles in the *Times of India* written *as long ago as the 19th of February* 1869: "The great objection to the well-system is its cost (not so much in the original cost as in the working it with the present ineffective mode of raising the water). The bullocks employed seldom last more than two or three years, and are worn out. The expense of well-irrigation is estimated at from forty to sixty rupees per acre per annum," It should be borne in mind that leather and raw hides are now fully forty per cent. dearer than they were some ten or eleven years ago, and as the water-bag or *koas* and ropes are invariably made thereof, they can at present only be purchased at nearly double the original cost. This unexpected and most extraordinary rise in the price of leather is undoubtedly attributable to unprecedented foreign demands, increase in local consumption, and to a decrease numerically in cattle from mortality or other causes. Recent satisfactory statistical information, collected and published by order of Government, has led to the discovery that in oxen alone there has, within a few years, been a decrease here from 156 254 to 149,192, and no praiseworthy efforts are I regret to say, being made either by Government as landlord, or the ryots as tenants, to improve matters in this respect. The circumscribed means of the latter necessarily preclude the possibility of any action of beneficial tendency being taken by them, and they are in consequence unhappy creatures of circumstances. It occurs to me that a grave question of considerable importance forces itself on the public mind, and must sooner or latter be confronted—*viz.*, what protective measures should Government as a morally responsible agent, take without loss of time to initate a system that will virtually reduce to a minimum the cost of raising water—a priceless gift of Nature—from deep wells, in order that the ryot may, with temporal advantage to himself, and the exigencies of the State, use it ordinarily, and in times of great emergency in sufficiently large quantities for irrigational purposes? The reply is by no means enigmatical, and will certainly be found in the following valuable lines of unheeded advice contained in the leading articles above referred to: "Few greater benefits could be conferred on the country than the introduction of an improved machine for lifting water. Such a machine must be cheap, simple, capable of being repaired by a village artisan, and of raising with a pair of bullocks, working on the level, twice as much water as a pair working on an inclined plane can raise with the bucket. Several machines for lifting water have, we believe, been recently invented, and we think Government should ascertain if any of them answer those conditions, and should then take measures for their general introduction."

A FRIEND OF GOVERNMENT AND THE RYOT.

Camp Ahmedabad, Jany. 22.

MR. OLIVER JONES ON COFFEE LEAF-DISEASE.

SIR,—On the 24th December 1879, I intimated by wire to the Editor, *Madras Mail*; the Secretary, Planters' Association, Ceylon, and the Secretary, Planters' Association, Calicut, that the true cause of coffee leaf-disease was discovered by me after careful investigation on the lower range of the Pulneys in the Periakulum taluq, Madura district. On the 19th of May 1880, my letter refusing the fungus theory as advocated by Mr. D. Morris, late of Ceylon, was published in the columns of the *Madras Mail*. Since then I have devoted the greater part of my leisure to further investigations of this very important and growing disease; particularly as it is of deep interest to the Ceylon Government, and to the planters of the colony and Southern India, and being confident that my views concerning this disease when perused will be received with pleasure, as thereby the crop-producing capabilities of the trees will be greatly enhanced, I have, after giving the subject my best consideration, resolved to publish in detail the true cause and best treatment that may be adopted not only to check and mitigate, but to cause an entire extirpation of a disease which has been very correctly denominated the planters' pest.

As introductory, permit me to state that the coffee tree belongs to the genus *coffeea*, of the order *Rubiaccœa*, and is exotic; as may be seen from the formation of its leaves, which if submitted to an examination are found to be made up chiefly of two portions, *a*, Fibrous, and *b*, Cellulair. The fibrous is made up of the petiole, the midule, and the veins proceeding from it. The cellular tissue is made up of a number of bags or cells varying in shape, while both fibrous and cellular portions are beautifully invested in a delicate membrane called the cuticle, which is abundantly furnished with stomata or breathing pores. In coffee leaf-disease it will be seen on examination that it is the soft cellular tissue that is destroyed, so that the normal functions of respiration, digestion, and exhalation are interfered with, and that the nutritive products and special secretions fail to supply the materials for growth and development, and the natural result is that numbers die away, while others soon look sickly and unhealthy.

What, then, produces this morbid change; does it lie in the sap of the plant being filled with infusoria from peculiarities of soil and moisture or fungoid organisms having their birth and growth from decaying vegetable substances, or is it due to causes other than those enumerated? But as the true cause of coffee leaf-disease does not lie in the blood of the plant being saturated with the infusoria or fungoid organisms, the *cause rationale* must be elsewhere. Walk into your plantation while the air is cool and crisp and make with your own hands a collection of diseased leaves, from the so-called pin-spots, to those where the whole leaf presents the appearance of an irregular sheet of fine rust; do not agitate the branches, and do not roughly break off the leaves, but most carefully remove the leaves by making gentle pressure at the foot stock, and after you have done this, adjust your microscope and place one of the diseased leaves under it, and you will, I am confident, very quickly detect the true cause of coffee leaf-disease. Having once seen for yourself the primary cause of this mysterious and growing disease, you would then be able to explain the meaning of the much spoken of dark brown spots, the rust, and threads of would-be mycelium. But I have failed to instruct you as to what you are to look for. It is evident I am desirous of permitting you to grope hopelessly in the dark. But if you are a naturalist and have some knowledge of entomology, then darkness shall be dispelled and light flood your path of investigation and research. I look into my note book, and there learn that the true cause of this disease bears the following description. I note it is long and cylindrical, but yet very small, it is made of several segments of which the antennæ represents the head of the insect, and the next three armed as they are with legs, the chest, and the remainder the abdomen and anal segments. The head has a pair of strong yet microscopic mandibles, a moderate sized upper lip, and in the centre of the lower lip is placed the spinneret or silk spinning organ. The body is clothed with spines, which surround each ring of a segment, and that while browsing on the coffee leaf and as seen under the miscroscope, its interior is filled with a red fluid. So that the true cause of coffee leaf-disease is both ocular and tangible. It has a name and belongs to the family *Noctnœlatœ*. It is after all the little moth, measuring scarcely half an inch across the wings and belongs to the order *Lepidoptera*. It lives, grows, propagates, and enjoys its short life among the beautiful jasmine smelling flowers of the coffee trees. This then dispels the fungus theory. It explains: *a* that the orange sporanges are nothing more than the excreta or digested cellular tissue mixed with coloring matter; *b*. that the threads of would-be mycelium are simply bands of fine silk as spun by the silk spinning organ of the larvæ; and *c*. That the dark brown spots are the reticulated portions of the leaf destitute of its cellular tissue, which had been devoured by the larvæ.

The next item of importance that needs a few cursory remarks is as regards the difficulty that has been experienced by others in failing to discover the true cause of leaf-disease. It is doubtless due to the fact that the larvæ being clothed with rows of spine, the rust, or more correctly speaking the excreta of the larvæ, adhere to them and thus completely hide them from view, and *2ndly*, they have a great tendency as soon as touched of detaching themselves from the leaves on which they may have been feeding with amazing rapidity; for example (*a*) I ordered a coolie working on the estate to make me a collection of diseased leaves. He soon returned with a handful. I then carefully examined them and found but two larvæ in a total number of some 200 leaves. (*b*) I filled my tiffin box with a very large collection made by myself (but took the precaution as a necessary step to line the inside with a clean piece of calico) and after the lapse of 12 hours examined the leaves and with difficulty detected a few; the majority, if not the whole had left the diseased leaves and fastened themselves to the calico lining of the box. This, then, accounts briefly, why others have failed to discover the true yet very simple cause of coffee leaf-disease.

And now as regards the treatment. It holds threefold facts—

1. Curative in character.
2. Arrestative, tending to prevent the spread of the disease, and—
3. Preventative or prophylactic, tending to prevent the origination of the disease.

1. Curative. As soon as all diseased leaves have fallen off, they should be collected into heaps and burned. It is very necessary that this act be made imperative; in fact I would advise the Government to enact a law concerning the observance of rules that shall be binding on all coffee planters. Because at this period the larvæ have all passed into their pupæ state and are protected from wind and weather, being as they are encased in a flocculent covering made by the silk they spin, so that nothing would destroy them but fire.

II. Arrestative. This may be done by employing children to collect in the eggs, which are made up of successive layers encased or surmounted with the hair stripped from the female moth, and as a rule lie concealed on the undersurface of the leaves—particularly as the number of larvæ escap-

ing from a single nest are quite capable of infesting a dozen or more trees.

III. Preventative. Prophylactic, since coffee leaf disease is highly contagious, so that the disease is capable of propagating itself by a process of contiguity. It is necessary that diseased as well as healthy leaves and plants be thoroughly dusted with the medicine as given below. In every case coolies should be instructed and trained to cast the dust from their hands into the plants, from below upwards, so that the remedial agent may come in contact with the stomata or breathing pores which lie on the under surface of the leaves. It will be well that the dusting be done in the eve or in the morning before sunrise, as the rays of the sun have a tendency to dissipate the medicinal action of the medicine. It may be also used with much benefit soon after a shower of rain or a slight drizzle. It is recommended that no less than three applications be used in every case with an interval of two days between each application. If the weather is dry, 6lbs. of the medicine may be dissolved in 12 gallons of water, and the solution injected on the plants from below upwards as instructed in the dusting of the dry powder. The medicine should also be largely used in the nurseries, as the disease is often fostered and propagated from them to the main plantation. I would advise, a, the dusting of the medicine on the plants soon after the flowering season, so that the moths may be prevented from depositing their eggs: b, it may be also used as soon as the leaves show the well marked pin-spots, as the powder is also very destructive to the larvæ.

Cocculus Indicus, deprived of its outer coat, 2lbs.

Camphor pulverised by means of a little spirit 1lb, aloes reduced to fine powder 3lbs, and pulverised chalk 6lbs. The *Cocculus Indicus* to be rubbed in a mortar with the chalk and then the aloes and lastly the camphor should be added. The medicine should be always used fresh; if not it has a tendency to deteriorate.—Yours faithfully,

OLIVER W. JONES,
Asst. Supdt., Medical School, Dindigul.

The Indian Agriculturist.

CALCUTTA, APRIL 1, 1881.

MR. BENSON'S TOUR.

We are much indebted to the courtesy of the various Secretariats for copies of the reports on agricultural and other cognate operations throughout India. At the same time we would point out one defect in connection with nearly all such documents; they are, as a rule, not issued for a very long period subsequent to the year to which they refer. As an instance in point, there is the "Report of a tour in the Cuddapah and North Arcot districts made in August 1879." This very interesting record only reached us a few days ago. Mr. Benson has written a very readable report of his tour, and he manages to compress much valuable information into the space of a few pages. The Cuddapah district is highly favored from an agricultural point of view, and it would seem by the report, that besides the natural advantages enjoyed by the rayats, a considerable amount of good work has been done by way of improving matters still more.

Manure is available in large quantities, and tanks and wells are plentifully scattered over the face of the country. High rents prevail, and we are told that Rs. 35 per acre have been paid. This is abnormally high, and from a consideration of the whole subject Mr. Benson draws the conclusion, that these high rents are the cause of the good farming which prevails. May it not be the other way, and may not the high farming for which the district has long been famous be the cause of the high rents. It is most probable that both hypothesis are true, and that the one reacts on the other. If the zemindars of India generally would only expend a little money in helping and encouraging their tenants, agriculture in the land would soon improve to such an extent that they would be repaid a hundred-fold for all their advances, and the condition of the rayat would advance in like proportion. It is impossible that rents can advance much higher than they are at present, owing to the impecuniosity of the rayats and to their indebtedness to the bunia. A very little help from the zemindars would relieve them from these burdens, and increased comfort and improved husbandry could not fail to follow, while for the zemindars enhanced value of land with higher rents would be a natural corollary.

The subject of weeds does not seem to be understood by the cultivators, as Mr. Benson reports the land as "extremely foul" in the irrigated lands, and of the lands unirrigated he says :—"The land under the crop (indigo) at the time of my visit was full of grass and generally dirty." Doubtless the comparatively high state of cultivation followed leads to a heavy growth of weed, but the rayat should not forget that his crop ought to get the sustenance filched from the soil by these weeds. They are, however, alive to the benefit to the soil of green manure, for we learn that they utilise the second growth of the indigo by ploughing it in.

One great advantage enjoyed by the cultivators is the abundance of wood fuel, which "prevents the use of *brathis*, so that the soil receives a good deal of what is removed from it by the crops raised." This is a strong argument for the planting of fuel reserves in the neighbourhood of every village.

Some very valuable hints are embodied in the report in connection with the value of canal irrigation of the "black cotton soil" of the district. This soil being deficient in the qualities necessary for thorough draining, does not benefit by irrigation as does a looser soil, the result being that the surface soil is liable to be "ruined by the presence of an excess of soluble salts." Irrigation from wells would seem to offer more advantages to such land, as with the necessity imposed upon the rayat of raising every gallon of water he required he would be less liable to flood his lands unnecessarily, and it is from this excess that the damage to clay soils arises. It is therefore a mistake, as Mr. Benson points out, to endeavour "to force water on the rayats." While referring to the generally high state of cultivation which prevailed in the district, he deprecates the mode of ploughing. He says :—

"It can thus be easily understood that the tillage usually performed is very little. A ploughing, which does not stir one-sixth of the surface soil to a depth of more than two or three inches, followed by a couple of scrapings of the surface is all the preparation the ryot of this neighbourhood usually makes for sowing his crops. In seasons of abundant rain this suffices, and the natural fertility of the land gives him crops which his labor has done but little to encourage. In seasons when the rain fails, the crops fail and he finds himself face to face with starvation; whereas in seasons of all but total absence of rain he should be able to raise fair crops on the soil he cultivates did he treat it well."

He goes on to tell us that this fact is well known to the cultivator, who now and again tries to plough deeper, but the want of the necessary cattle power presents an insuperable obstacle.

"Although the usual system of tillage is poor, the rayats are aware of the value of deep cultivation, as is shown by the use of a large plough yoked to several pairs of cattle; but the chief value of the work done by this implement is set on the effect it has in the destruction of hariali grass (*Cynodon dactylon*). The effects of the use of this implement are said to be observable for ten years, but the area annually operated on is very small; and the use of this description of implement is not at all universal. The crop usually taken immediately after the deep tillage is Bengal gram (*Cicer aristinum*). Did this practice prevail over the greater part of the black soil area, and were it regularly performed, there would be little danger of the locality suffering from a failure of crops, which, when it occurs, is most severely felt here, owing to the absence of roads for the transport of food-grain into the district."

The recent exhibition at Lucknow may tend to remove this difficulty as several improved ploughs were shown there, and when we receive the report, we may find that something has been done in this direction. To this shallow ploughing is attributed the failure to make cotton a profitable crop, the outturn in 1878 having averaged only 41lbs. of cleaned cotton per acre.

The objection urged by some to the introduction of wells for irrigation, that those latter draw their water from tanks by intercepting the percolations, is disposed of by Mr. Benson. He tell us that he has examined many wells in the neighbourhood of tanks, and he does not find larger supplies of water in them than is to be found in wells distant from tanks. He

also says, and with reason, that if these wells drew their supplies from tanks above their level they would always be overflowing while there was any water in the tanks, but he does not find this to be the case. He therefore concludes that "they can scarcely be said to draw more water from the tanks above them than that which naturally soaks slowly away by subsoil drainage."

We propose turning our attention to the subject of wells for irrigation at an early date. The quantity of manure used is about 10 loads per acre. This is equal to 3⅜ tons.

The quality of the cattle claims our attention next, and we are told that these are comparatively good. Mr. Benson has a few fitting remarks on the subject of improving the breed, and as applicable to all India we quote the following :—

"The injurious effects of the use of any bull as a sire are well known, and why, in order to prevent this in some measure, compulsory castration of all but well-developed animals might not be resorted to, it is difficult to see. The proceeding would not be a hardship to the people, whilst, as a general benefit to the country, it would be a very great advantage."

In considering the condition of the cultivation Mr. Benson comes to the conclusion that he is almost a hopeless subject, and winds up his remarks thus :—

"Causes and effects follow so slowly in agriculture, that the difficulty of following out the teaching of experiments is very great. If we add to these agencies the extreme poverty, he manifold superstitions and other influences affecting the rayat, it is difficult to reasonably expect that in the longest life of effort for agricultural improvement much can be effected in the modification of his present practices, unless pressure is brought to bear on the cultivators by their landlord—the State."

We do not quite agree with his conclusion, we do not believe "pressure" on the rayat will do any good. What he wants is help and encouragement. By all means, let us have a little gentle pressure, but let it be applied to the landlords. After suggesting a few improvements which he would introduce in the relation which exist between the Government and the rayat, or it may be the zemindar and the rayat, he concludes as follows :—

"The problem then reduces itself to the attraction of a greater amount of capital to the land, and to the inducement of natives of the higher classes to embark directly in a pursuit which has until now been looked upon as the proper employment for serfs. To induce attention to the honorable position which an agriculturist occupies, to foster an interest in his pursuits, to offer persons, who have had their attention turned to husbandry, an opportunity of acquiring the best possible knowledge of the science and practice of that art, and attempts to induce such attention, together with endeavours to scatter agricultural information broadcast throughout the country, are all objects which will bring Government a return, but from which it is hopeless to expect immediate results ; and, considering the position the active occupation of a farmer occupies at present in the estimation of the native community, can only be hoped to bring forth results if most carefully fostered and watched over by the State."

This mode of improving affairs seems a little too drastic, as it in fact amounts to improving the rayat off the face of the land altogether, and substituting in his place "natives of the higher classes." This might do were we dealing with an entirely new country, and were trying to regulate the class of immigrants we ought to encourage, but here we have the evil, *viz.*, the poor ignorant cultivator, and our duty is not to abolish him, but to try to improve his position. In effecting this there does not seem to us to be anything in the way, which is beyond the ordinary functional operation of good government. It is a mistake to look upon the cultivator as a man who may be got rid of by the introduction of a better class of native. He is not to be got rid of by any one within our reach. We cannot possibly do without him, and he is the most important factor in our census returns. The country might somehow pull along without the better class of native, but it cannot exist without the rayat. Hence the necessity of making an intelligent effort to improve him, as in doing so we lay the foundation of a better condition of national prosperity and offer more material guarantees for good government.

FERMENTATION.

THE keystone in the manufacturing of tea is fermentation. There are other stages in the course of manufacturing when the utmost care is necessary, in fact it may truly be said that such extreme care is necessary at every stage. But of fermentation it is peculiarly true. During the course of the afternoon the careful manager decides where he will pluck to-morrow, and as the leaf arrives at the factory, he sees it weighed and preparations made for withering. Having given his instructions on that score, he need give himself little further concern about it, as the ordinary intelligence of a factory sirdar is usually quite up to taking care of the leaf in this initial process, and so in fact he may act with regard to almost all the other processes through which the tea is passed from leaf to chest. We do not of course mean to imply that he can safely leave to natives all the responsibility of taking due care of the work in every process. What we mean is this. If he has a good native staff he can issue his orders, and if he can depend on the staff, his mind may be comparatively easy as to the general result, he, of course, casting his eye around to see that his instructions are being literally and intelligently carried out. It is not so, however, with the fermentation stage. This must be attended to personally, and if he be a conscientious manager, there is no man in the factory to whom he feels he can depute the responsibility of deciding the exact moment when to check fermentation by breaking up the balls. We are perfectly aware of the fact that a large number of managers are themselves unable so to decide with judgment, and such usually leave this to the head tea-maker. We also fear that there are some who perhaps knowing well how to attend to this, yet neglect either through indifference or laziness. To such, and we are convinced they constitute a small minority, we have of course nothing to say that would at all interest him. The conscientious manager, however, who takes an intelligent interest in his work will agree with us as to the extreme importance of this subject.

The object of fermentation is to soften the harsher qualities of the flavour, and if fermentation is prolonged unduly, the flavour is almost entirely annihilated, compelling the factory staff to fire the tea to the verge of burning in order to develop some flavour, which after all, is not that wanted. Where panning is practised, this fault may, to a certain extent, be modified, but where *panning* is tabooed, resource has to be had to the *drying* process to endeavour to recover some of the lost flavour. As we have said this is hopeless, *a* flavour can to a limited extent be imparted, but not *the* flavour. If on the other hand the fermentation is checked at too early a stage, the reverse is the result, the flavour is too strong, and like all imperfectly manufactured articles of the kind, gives evidence of the insufficient fermentation in a rough pungent liquor which may be liked by those whose palates have become satiated with continual tea tasting, or by that class who have no appreciation of delicacy in food or drink, but which does not tend towards making Indian teas more popular in England, and this it is we should all aim at. We have formerly spoken of the real object of making the rasping tea thus described, *viz* :—for the purpose of strengthening weak China teas, and will not enlarge on it here. The question that now remains for us to notice, having pointed out the difference between under and over fermented tea, is what then is the proper amount of fermentation to give the tea. When the leaf is made up into balls and laid aside for fermentation the colour of the leaf is green, with a more or less decayed look about it, and immediately these balls are formed, fermentation commences. How long then from this moment are the balls to stand undisturbed ? It is quite impossible to fix a time, because the degree of fermentation going on depends on so many things. The condition of the leaf, the manner in which it was withered, or rolled, and the condition of the atmosphere all affect it very materially and make it quite impossible to fix a time. There are, however, two ways of knowing, *viz.*, by smell and sight. The manager takes up a ball and having broken it in two, runs his nose into the fracture, and his sense of smell tells him when the proper degree of fermentation has been attained. It is of course impossible to describe this peculiar flavour in print, and a correct appreciation of it is only to be acquired after considerable experience and practice. The other mode is simple, but not quite so exact. When fermentation commences the green tint of the leaf gradually changes into a dull dark brown, and this does not

occur on every leaf. When, for instance, this brown tint has pretty well spread over the ball, it will be found mixed with the original green, and the moment the outside of the ball shows about half brown is about the proper time to stop the process, of course inside it will all be brown. Then the balls should be broken up and prepared for the next process. If this be done earlier, the outturn of a trial cup will be green, and if it be delayed, the outturn will be black. What is of course wanted is the almond brown of the broken, and to attain this standard the utmost care must be taken, that the fermentation is continued up to the proper point only. We are perfectly aware that many planters do not attach so much importance to this subject as we do, but we are convinced that on nothing, so much as on true fermentation, does the quality of the manufactured article consist.

THE LUCKNOW EXHIBITION.

WE have not yet received full details regarding this exhibition, and do not expect to do so in time to notice the show fully in this number ; we propose, however, to offer a few remarks in the meantime.

The local paper notices the very subordinate position which agricultural subjects have occupied during the progress of the meeting. Speaking on this subject the *Express* says :—

"In fact, produce and implements appear to have taken up quite a secondary position throughout the recent Exhibition, and the phrase is a misnomer and misleading. The exposition has been one of industrial art primarily, the cattle section coming next, followed by that of implements and machinery, and the staple products of the province lagging far behind. Believing, however, as we do, that these latter are of quite first importance in an agricultural connexion, we can only attribute the seeming neglect of them as due to the inexperience and haste which has characterized the promotion of the meeting and its adjuncts *ab initio*. This is a first attempt in a most important direction, however, and we may expect that the fruits of present experience will not be lost when the next Agricultural Meeting comes round."

This is of a piece with a good deal that has taken place in recent years in connection with agriculture. Another illustration of this was the *laissez faire* system under which the now defunct Agricultural Bureau was carried on. Agriculture in its true sense seemed the very last thing thought of, and hence the department was gradually dropped. This exhibition was originally intended to be an agricultural one principally, and now we learn from the local print that the subjects of implements and machinery, and the staple products of the province "lagged far behind". We are willing, however, to accept the excuse volunteered, that "inexperience and haste characterized the promotion of the meeting, and its adjuncts *ab initio*," and we cordially echo the hope that "we may expect that the fruits of present experience will not be lost when the next Agricultural Meeting comes round." Several samples of wheat, *dhan*, maize, and cotton are highly spoken of ; of the latter one raised by Kunwar Harnaun Singh was highly valued, and a strong hope is expressed that the cultivation of such a quality of cotton will be more generally encouraged by the Agricultural Department of the province.

A feeling of discontent is expressed at Mr. Martin's sample of American tobacco having only been awarded a second prize. It was grown from American seed and is described as incomparable for length of leaf and cure, and should certainly have had a first prize for a distinct quality. In fact, being the first grown in Oudh on an extensive scale it might well have been honored with a medal. In our opinion, another sample from native seed, but well cured, should have had the 2nd prize instead of the Biswa parcel, which seemed to us to be very black, hard, and fermented.

We are, of course, not competent to form an opinion on this point. Several other articles are mentioned as having been particularly good, but we prefer not to go into the subject until we have the complete report before us.

We cordially endorse the views expressed by our Lucknow contemporary on the importance of making every effort to improve our agricultural modes.

"Nothing will improve this country so much, or do more for the advancement of genuine agriculture, than the co-operation of the unemployed capital and intelligence of England. By means of these aids, the ignorant, exhausted, and apathetic people of India may be led to the higher position the wonderful resources of the country open out to them ; but which are practically unattainable unassisted by the capital, energy, and 'push' of civilised European nations. The Americans would, no doubt, very soon remodel and reorganize India,—in an agricultural connection especially,—as they have the knack of adapting themselves to the 'ways and means,' and the requirements of the land they enter on the possession of, and are not afraid of honest hard labour of every kind, whilst their freedom from extremely conservative habits of life leaves them open to adopt new views. India, left to itself, can make no advance in either agriculture or anything else. We consider that the Department of Agriculture and Commerce has most important functions to discharge. And, upon the breadth and comprehensiveness with which these duties are entered upon and discharged depends the future of the country, whether for weal or woe, in its most vital interests."

We think the committee have adhered too strictly to the letter of their instructions in excluding cattle other than for ploughing purposes. On this subject Mr. Fuller writes to the Secretary of the Agricultural Meeting :—

"A very large number of the bullocks exhibited were not plough cattle, but had been broken for use in carts and raths. No provision had been made for cattle of this description in the prize class, since they cannot properly be classed as 'agricultural.' The committee, however, having regard to the number and excellence of the exhibits, determined to create an extra class for them, and unawarded some prizes out of the large surplus which remained rewarded in the other classes."

Doubtless this is technically true, but carts and raths play a not unimportant part in the economy of agriculture, and we should have preferred to have found the animals suitable for such work coming in for a share in the prizes, and in the programme of the meeting.

There seems to have been rather a *fiasco* in connection with agricultural implements, especially ploughs. Several competitors, we are told, were prepared to enter the lists, but a very reasonable suggestion made by one of these gentlemen having been pooh-poohed two competitors are said to have withdrawn. Assuming the correctness of the report we do not see how they could have done otherwise. We have transferred Mr. Martin's letter to the *Express* to our correspondence columns.

We shall possibly return to this important subject when in possession of fuller information.

EDITORIAL NOTES.

IN redemption of our promise, we have pleasure in drawing attention on the lecture on "Forest Conservancy in India" delivered by Sir R. Temple. We do not consider Sir Richard an authority on the subject, in the same sense that an expert would be ; at the same time there is a considerable amount of sound sense in what he says.

THE report on the cotton production of the North-Western Provinces and Oudh during the year ending 31st March 1880, has only now come to hand.

It has long been a puzzle to us how cotton was still retained as an article of production. The outturn in India is so small, and the relative value of the produce to other crops so miserable that we have never been able to understand what object the cultivator has in continuing to grow it year after year. In these provinces no fewer than 1,270,121 acres were under this crop, the quantity of cleaned cotton produced being 8,29,601 maunds. The statistics for the past three years are as follows :—

	Acres.	Maunds.	lbs. per acre.
1877-78	735,635	255,193	28·4
1878-79	1,358,405	1,035,743	62·5
1879-80	1,270,121	829,601	53·5

During the last two years, the average price per maund was Rs. 15-13 5, and the average produce per acre 58 lbs., consequently an acre gave a gross outturn of Rs. 11-3-3.

The average outturn of differently cultivated land was as follows :—

	lbs. per acre.
Richly manured land	74·6
Ordinary „ „	53·3
Poorly „ „	44·3

Now we know that the average production in America is 300lbs. per acre, and notwithstanding the many acknowledged drawbacks in India, surely 53½ lbs. is too low.

THE Irrigation Report of the North-Western Provinces and Oudh for the *kharif* crop of 1880-81, points to a larger amount of work done than in the previous year, although it was not up to that of 1877-78. The following shows the area irrigated :—

1877-78	731,583	acres.
1878-79	660,026	„
1879-80	555,641	„
1880-81	700,139	„

So much depends on the state of the rainfall, that the quantity of and irrigated can never be safely predicated. This area was only 4·89 per cent. of the cultivated area. The cost to the occupier was as follows :—

1877 78	Rs.	2-56	per acre
1878-79	„	2-81	„
1879-80	„	3-14	„
1880-81	„	2-70	„

This charge only covers one crop ; so that we may assume five rupees as the annual cost of irrigating an acre. Surely it could be done cheaper by means of wells.

THE Superintendent has issued his report of the Botanical Gardens and Park on the Nilgiris for the year 1879-80. A great deal of useful work seems to have been done at comparatively little cost, the outlay on the part of Government having only been Rs. 6,260. Great success has followed the cultivation of the *Ceara* Rubber trees; the growth was marvellous, one tree having grown 14 feet in twelve months. Several medicinal plants have from time to time been tried, but with indifferent success ; the epecacuanha, peppermint, and rhubarb, being decided failures. It is thought that the climate is too severe for them, hence they are being removed to lower elevations for further experiment. *Taraxacum* and *digitalis* have succeeded beyond expectation. We had expected no less, as these plants grow well in the comparatively cold climate of Scotland. In order to show what is being done, we summarise the sales of the year :—

	No.	Value.		
Fruit Trees ...	464	144	2	0
Timber Trees ...	2127	214	4	5
Ornamental Trees	8151	1,080	2	0
Packets of Seeds ...	4395	862	12	10
Bouquets of Cut-flowers	252	140	8	0
Sundry Receipts ...	...	335	7	7
	Total value Rs.	2,777	4	10

A RECENT experiment in the Karwar Municipality with sorghum and Planter's Friend is not without interest.

The experiments were tried on small plots equal to the fortieth part of an acre, and the result was as follows, reduced to lb. per acre :—

	Green Fodder.	Cane.	Jaggery.	Seed.
From Mangalore acclimatised Sorghum	6,000	5,010	120	1,[illegible]0
From Saidapet Sorghum	6,000	5,32[illegible]	160	1,600
From Mangalore acclimatised Planter's Friend	11,200	10,480	390	1,3[illegible]0
From Saidapet Planter's Friend.	12,000	11,280	450	1,700

This is a very satisfactory outturn, and seems to point to the Planter's Friend as a very valuable plant.

THE Mysore Administration Report for 1879 80 contains much that supplies food for thought, and the first thing that strikes us is the fact that there are "3,511,828 acres of arable waste land unoccupied at the end of 1879-80." We are continually hearing that the land is suffering from over-population. We are afraid that want of capital is the prevailing want. The population of Mysore is 172 to the square mile, there is therefore ample room for many more people here. Much of the report is, as a matter of course, taken up with fiscal and judicial details, but our present concern is with the departments of "Production and Distribution." The very first paragraph under the head of "Agriculture" reveals to us a blot which seems to us to clog every effort we make in improving our methods of agriculture. It is this :—

"Since the closing of the Experimental Farm at Bangalore, 25 acres of the ground have been made over to the Superintendent of the Lal-Bagh for experimental cultivation. The outlay on this during the year was Rs. 458, the income Rs. 405. The Superintendent is to try and make the ground self-supporting as well as useful for experiment, and he almost attained that in his first year."

Here we are immediately brought face to face with the difficulty, "The Superintendent *is to try* and make the ground *self-supporting*." This of course chokes every effort at experiment, because no Superintendent will run the risk of losing the good opinion of his superiors in office, by experimenting, unless he knows he will succeed, at which stage experiment ceases. The very word "experimental" used to describe the farm, points to trials and risks. But acting on the instructions received, the Superintendent must have no "risks ;" he must experiment so that he may be certain to succeed.

Several new trees and plants were introduced at the Lal-Bagh, Bangalore, with more or less success, and the vanilla experiments were continued. We are told that they "are only now beginning to recover from the three years' drought which nearly killed them, and have borne a good crop." Such a valuable plant as the vanilla ought to be placed beyond the reach of injury from drought. We are pleased to learn that they are producing a crop, as we feared the elevation at Bangalore might have proved too cold for them. This plant will never, we fear, become a popular one with the natives, at least for a considerable time, as there is a difficulty in fertilizing the flowers, which operation, a very delicate one, has to be done by hand, owing to the absence in this country of the insect, which in the economy of Nature, ordinarily performs this office. The year's return of crops is thus favorably spoken of :—

"A very fair harvest was the general feature of the year ; the staple articles of food, rice and ragi, were not reaped in bumper crops as in the previous year of plenty, but the yield was good, and in some tracts horse-gram and ballar yielded beyond expectations. Diminished fall of rain in Kolar and Hassan taluks told to some extent on wet cultivation under tanks which failed to secure their usual storage of water."

The following are the figures regarding cultivation :—

	Square miles.	Percentage.
Cultivated	7,351	30
Culturable waste	5,487	22
Unculturable waste	11,906	48
Total	24,744	100

The statistical tables tell us that the people are not well supplied with agricultural implements, there being only 571,968 ploughs in the province. It follows that there is only one plough for every seven acres under cultivation. In the matter of carts they are even worse off, there being only one to every 55 acres. These are the little things that tell of prosperity or the reverse. The average rent of land varies from Rs. 1-11-4 per acre for oil seeds, to Rs. 7-1-5 for sugar-cane, and the value of labour from 2 to 10 annas per day for unskilled, and from 4 annas to one rupee for skilled. Upon the whole the report speaks of progress and general prosperity.

A MEMORIAL has been addressed to the Secretary of State for the Colonies by the Planters' Association in Ceylon in respect to the proposed introduction of the medical ordinance. The planters state that no special law is required to provide for the medical wants of the coolies, but that the extension of the Civil Medical Department will be sufficient to meet the wants of the laborers. They add that since the introduction of the coffee enterprise in Ceylon, that is from 1843 to 1880, no less than 2,700,000 coolies passed into Ceylon, and that the coolies are better provided for than in their own country. During the famine of 1877-78 about forty thousand

natives from Southern India found means of subsistence in Ceylon, and the benefits derived by the coolies were publicly acknowledged by the Collectors of the Southern districts. The memorialists maintain that the prosperity of Ceylon is to be chiefly attributed to the planting enterprise—that in 1859 the general revenue of Ceylon was £747,000 against £1,400,000 in 1880. The Civil Medical Department has increased from 39 surgeons and assistants to 74; the twelve hospitals in the colony have been increased to 27, and the annual expenditure on account of medical comforts increased from £18,000 to £61,000 in twenty years. The memorialists state that if the medical wants of the laborers are to be increased, they should be at the expense of the public revenues but not by the introduction of a special ordinance. They will provide for the medical wants of their coolies, but they see no reason why special taxation should be resorted to.

THE *Behar Herald* deprecates the extension of poppy cultivation that has been taking place in the Behar Agency during the past year. Our contemporary writes thus :—

We wonder why more lands are not brought under poppy cultivation in the Benares Agency, and the poppy cultivation in the Behar Agency thrown out altogether. The total quantity of land under cultivation in the Behar Agency during the past year was 4,15,280 beegahs, and the produce 41,268 maunds, *i. e.*, about 4 seers per beegah : In the Benares Agency, the total quantity of land cultivated with poppy was 3,95,820 beegahs, and the yield 56,937 maunds, *i. e.*, at the rate of 5 ½ seers per beegah. If this course be followed, more than one lakh of beegahs can be drawn out from poppy cultivation altogether, and utilized for the production of food-stuffs, without its telling in any way against the revenue now derived from opium. It is clear that lands in districts comprised in the Benares Agency yield more than the lands in the Behar Agency, and instead of bringing more lands under poppy cultivation in Behar, strenuous efforts should be made to increase the area of poppy cultivation in the North-West. As it is, even during the last year, it appears about 10,000 beegahs more have been brought under poppy cultivation in Behar. This is altogether a wrong course to pursue, and it is to be hoped that no more mischievous zeal should be spent in this direction.

SPEAKING of the results of a serious experiment at a recent ploughing match, Mr. Robertsion says:—

It will be observed that the country plough did not penetrate the ground to a greater depth than about 3 inches, while the improved ploughs, the draught of which was very little greater, worked the soil on the average to a depth of about 4½ inches. The section of the furrow made by a country plough is a triangle with the apex downwards, while that made by the improved plough is a rectangle. Assuming that the furrow of a country plough was 4 inches wide at the top and 2 inches at the bottom, in ploughing a mile the plough would move only about 12 cubic yards of earth, and this, be it remembered, is only stirred and loosened after the manner of a cultivator, and not raised and inverted. In an ordinary day's work, the country plough would probably travel 16 miles, loosening and stirring only about 196 cubic yards. The improved plough, working to the depth of 4½ inches, would turn a furrow 8 inches wide, the section of which would measure 36 square inches against 9 square inches, the area of the furrow section of the country plough ; while in a mile the improved plough would turn over 49 cubic yards of earth, or in a day'swork of 12 miles, 587 cubic yards ; thus performing as much work as three country ploughs. In these caclulations I have made an allowance for time wasted at the headlands. Ryots, therefore, whose holdings are above 50 acres in extent could readily obtain the means required for purchasing an improved plough or ploughs by selling one or more of the pairs of cattle, the services of which the adoption of the improved plough would enable the ryot to dispense with. The extra cost attending the employment of the improved plough, would be met by the lesser expenditure on labor and cattle-keep, from fewer laborers and cattle being required than when the holding is cultivated entirely by country ploughs."

A NATIVE gentleman who "has a large landed stake in the province (Oudh) and is altogether an intelligent representative of his class," writes to the Lucknow *Express* in reference to the recent Taluqdar's Agricultural Meeting in the Province. He thus depicts what he calls the "current ideas" of the educated native community as regards these meetings :—

Those natives who take a real interest in agriculture—that is an active part in its improvement, progress, and welfare—are, confessedly and unfortunately, but few ; but those who do so, and are able to read English newspapers take the greatest interest in the accounts given therein of these meetings, and from which many, mentionable, have initiated, what has been brought home to their minds as a better system, if properly managed, for Indian agriculture. They also can appreciate the unity of purpose, and essentialities for which these meetings take place in England the way in which they are conducted, and the season in which they are held so as to cause as little inconvenience as possible to those most interested, and also afford a pleasant trip for holiday pleasure seekers. They know too that these Institutions have raised the status of farmers and of general agriculture in, as also the wealth of, the United Kingdom, and that, had they not been instituted, the husbandry and husbandmen, and the wealth of England and Scotland, would, in all probability, have been at this day in a somewhat similar state of poverty and exhaustion as their own wretched ryot and soil presents at the present moment. These few reflecting men also give much thought to the possibility (or improbability ?) of their ever witnessing such a unity of purpose, even among the great Landlords and Raeses of India—for in this matter the ryot has not, nor can hope to have in this generation—any place—It is to these great men, in conjunction with the Government of her Imperial and most Gracious Majesty the Queen and Empress of India that such a desire can be fulfilled, but the way towards doing it, may not be according to the will or the liking of either. It is believed, however, that *the only* means which ever can, or will effect it is an equitable and permanent land-tax, long leases to tenants granted by, or under the protection of the Government, and no rack renting. When these things come to pass, poverty and wretchedness will fly before the march of improvement, and improvement would eventually bring about unity of purpose, and raise the status of the Indian farmer too. *Then*, an active interest will be felt *in all things* connected with agriculture, and agricultural meetings will be upheld, and be supported by the heart and desire of this country. But now !—what interest *can*—even the proprietory ryot, feel in or for these meetings ? They now consider them to be "a tamasha" for the *Sahib logue* to enjoy themselves at, and for showing frippery tools or may be expensive machinery unsuited utterly for India—to Rajahs and other great men. If these and the Government combine at the present meeting and form resolutions which will hereafter establish equitable justice for the cultivators of the soil, assist them with genuine guidance in agricultural matters, and *feel an interest* in their being carried out, propound and demonstrate to them a better mode for cultivation than their own, an easier method to effect it and to relieve the heart-breaking toil—themselves and starving cattle undergo—to perform it. Then, we natives would gladly and joyously hail all advances made which would, when proven, add to the relief of our necessities, and prospective future welfare.

IN feeding our domestic animals, care should be taken that they receive enough of good wholesome food and no more. When this point is reached, the food of a healthy animal will be digested and assimilated with the blood, tissues and other parts of the system. If more than a sufficiency is given, the result will be a loss in two ways. First, the food is lost, because the animal will not have digested it. Second, the stomach being overloaded, the digestive organs will become more or less disarranged and disordered, and the animal will not be able to assimilate the food in the healthiest manner. As near to, but inside the limits of capacity for digestion, is the point to aim to arrive at in feeding for profit, and, other things equal, the animal will have a good appetite, good digestion and give the best returns for food consumed. This is a subject deserving more attention than it ordinarily receives.

IT may not be generally known, yet such is the fact, that fatting stock may be thriving and yet not gain in gross weight. For instance, cattle taken from grass, or other succulent food, and put upon feed of the best of grain and hay, or other dry forage, may, and frequently do, grow fat and lose in weight. The cause of this is, that grass is a less condensed food than grain, contains more water than the drier food, distends the stomach and intestines to a greater degree, and hence they contain more of weight, when full, than they do when concentrated food is given. An illustration of this was given a few days ago, in the Pittsburg (Pa.) *Stockman*, in reporting a case in which two car loads of cattle had been fed all the corn they could eat, during three months, and "had not gained a pound in gross weight in that time." The cattle, however, were evidently better fatted and an increase of $1 per hundred in the three months gave the feeder $13 per head advance on cost. This matter is well understood by shrewd speculators who arrange to

have their cattle taken from grass and fed by other parties at an agreed price per pound for the *increase* of weight. We have known of instances in which the feeders have lost largely, in one instance a tenant farmer lossing his entire crop, while the unscrupulous owner of the cattle made an enormous profit. The *Stockman's* report accounts for the cause of these losses.

SCINDIA'S Paper Mill has at last been completed under the supervision of Mr. Cowasjee Wookerjee, who selected and brought out from Europe the machinery with all the latest improvements. The mill turned out really excellent paper several hundred yards in length, on the occasion of its first trial, which took place on the 9th instant. Yesterday (Thursday) Scindia, who had not previously been near the mill, held a special durbar in order to inspect the sample rolls of paper, which is here manufactured from karbi and rags and is pronounced to be of a superior texture. His Highness was much pleased to ascertain that the first European industry established in his territory had so far proved a complete success. The mill is to be visited by Scindia in State probably next week. Great praise is due to Mr. Wookerjee for the untiring zeal and energy he has shown in connection with this scheme, from which considerable results may be expected. The mill, indeed, promises to be a great success, especially as skilled European engineers and workmen have been employed to carry on the work.

WHATEVER opinions men may hold as to the injurious effects of opium-smoking, and whatever may be thought of the past history of the Indian opium trade, it is now evident enough to practical men that the time has gone by for any useful agitation against the carrying on of that trade in the future. It is certain now that the Chinese would not want opium in abundance, even though not another ounce were allowed to leave the shores of India. The drug is now largely produced in China, and the industry seems to be steadily increasing. Persia is rapidly extending the cultivation and trade; and as both the Persian and the Chinese drug are much cheaper than the Indian, the danger of the future seems really to be that the Indian drug may be driven out of the field. The practical question for India is not whether we may rightly continue to send opium to China, but how we can adjust our revenue and expenditure so that we may not be made bankrupt by a falling off in the opium revenue, which, if not certain, is very far from being improbable.

THE *Pioneer* has the following as a possible cure for the vine disease. The *Evenément* of Paris declares that the vines are about to be avenged. It appears that a communication has been made to the Academy of Science, to the effect that there has been discovered in California, the all-productive, an insect which is the mortal enemy of the *Phylloxera*, and devours it with avidity. Savants have only to decide whether it is possible to acclimatize this crowning mercy in insect form; and it is said that the great reward of one hundred thousand francs awaits the successful zoologist who adds this new member to the fauna of France. This sum, or ten times its amount, would be a small price to pay for destroying the pest that for the past two years has been ravaging the vine-growing parts of France. In 1879 the outturn of the vintage was only 550 millions of gallons or about half the average produce of the ten preceding years, 1,075 millions of gallons. There has fortunately been an improvement in 1880, the outturn being 650 millions of gallons.

The money loss on the two years was about forty-five millions sterling.

THE Government Resolution appended to the report of the Irrigation Revenue Report of the N. W. P. for the year 1879-80 is short and to the point; so we may quote it without putting too serve a strain on the patience of the reader. It is as follows:—

The results summarised in the Chief Engineer's review are decidedly satisfactory. The year under consideration was one of unusually abundant and timely rainfall when, it might be supposed, canal irrigation would have been quite unnecessary; but not only did the canals pay 4½ per cent. on the total capital of 624¼ lakhs of rupees, invested in the irrigation works of the North-Western Provinces, but the steadily increasing area of sugar-cane, rice, indigo, and cotton point unmistakeably to the steadily increasing prosperity of the cultivating community dependent on the canals. As year by year the extension of light railways in these provinces afford a continually widening market for the valuable produce of the canal irrigated tracts, his Honour is convinced that the capital and wealth accumulated in them will assure the stability of the land revenue, and place it in a position independent of the fluctuations of the seasons. The revision of the agreement under which the financial responsibilty for and general control of the canals in these provinces was in 1877 made over to the local Government has lately engaged the Lieutenant-Governor's serious attention, and his Honour is desirous of a re-arrangement of the terms then approved, admitting the responsibility of the province for interest at 4½ per cent. on all capital invested in canals in the province, whether classed as productive or agricultural works, and the claims of the Government of India to all land revenue and owner's rate due to the operation of State Irrigation Works, but asking in return that the very doubtful item of two lakhs (estimated net profits of these works in 1877), and the claim to half of any advantage gained by the province, shall be abandoned by the Government of India. His Honour's desire being to expend all available provincial funds on Provincial Light Railways, he would prefer that all canal capital should be supplied by the Imperial Government. The Lieutenant-Governor fully endorses the Chief Engineer's remarks regarding the good work done by the canal establishment, and is confident that its officers will maintain in the future the high reputation which they have earned in the past.

AN American contemporary thus advises the farmers as to seed:—"Now is a good time for farmers to be looking about them for selecting seed-corn—we mean those who have not taken time by the foretop and selected their seed corn in the fall, which all should have done. In some sections the crop of 1880 is reported 'light and chaffy.' All such corn is more or less deficient in vitality, and hence may not be fit for planting. Great care should be taken to secure seed that will be sure to grow when placed in the ground. We have known individual farmers to lose hundreds of dollars in a single season, by planting corn put in shocks or cribbed when imperfectly matured, which consequently became damaged to an extent that destroyed the vitality of the germs. Take good care, therefore, to have good sound seed, and have it selected early. Should there be any doubt about its growing, a good plan will be to have the seed all shelled and thoroughly mixed, then take a handful or so of the mass, plant it early as practicable and note the percentage that sprouts well. This will afford data by which to determine the number of grains to be placed in a hill, or dropped singly in the row, which we believe the better plan. By the way, when corn is planted in hills, farmers should drop exactly the same number of grains in each hill. By so doing, they may save a deal of labor often expended in thinning, or re-planting, or neglecting to replant, which is often done."

Much of this is applicable to India.

IT is astonishing that the cultivators of India should never have considered it a part of good farming to cultivate root and other crops purely for cattle feeding purposes. We give the results of a series of experiment at home, from which it will be seen that a crop of 30 tons (818 maunds) of turnips has been raised from an acre.

AT a recent meeting of a farmers' club in the United States, a member said:—Without food of good quality the best animals from purest strains deteriorate and become unshapely. Many years ago one of the first Durham bulls was introduced into this country. The food and care he received were so different from that to which he had been accustomed that his stock fell into disrepute. There must be increased care, and a better quality and abundance of food, to keep up the standard character of improved stock. Another:—'Believe in good feeding if you would have good stock. First, they must have grass. Young stock should be fed on bran and oats, which makes muscle. To fatten cattle corn is best, but for growing cattle oats are better. A member said, 'You can feed to fatten, for milk or for muscle. A milch cow should not be fed as you would a fattening steer. It is an admitted fact that corn will fatten, but it does not make milk. Bran is better for that purpose. The practice among dairy people of feeding slop encourages disease.' Another: 'For butter, yellow corn meal is better than anything else. It makes butter of better colour than white meal. In the vicinity of New York thousands of barrels of swill are fed to cows every day. It makes,

an immense quantity of milk, but does not add to the health of the animal or the quality of the butter.'

THE following notes anent the preserving of posts and wood which we extract from the *Mechanic*, will prove of great value and interest to all planters. The method commonly in vogue is to simply char or tar the post, but unless we both char and tar the posts, the method is of no avail. For we read, "Should the poles only be charred, without the subsequent treatment with tar, the charcoal formation on the surface would only act as an absorber of the moisture, and, if anything, only hasten the decay. By applying a coating of tar without previously charring, the tar would only form a casing about the wood, nor would it penetrate to the depth which the absorbing properties of the charcoal surface would insure. Wood that is exposed to the action of water, or let nto the ground, should first be charred, and then before it has entirely cooled, be treated with tar till the wood is thoroughly impregnated. The acetic acid and oils contained in the tar are evaporated by the heat and only the resin left behind, which penetrates the pores of the wood, and forms an air-tight and waterproof envelope. It is important to impregnate the poles a little above the line of exposure, for here it is that the action of decay affects the wood first, and where the break always occurs when removed from the earth or strained in testing."

THE "Big Gooseberry" is not one of the productions of Fiji, and newspapers are therefore defrauded of many a legitimate item. The island of Mago, has however, endeavoured to provide a substitute with very creditable success. On the occasion of the Wentworth's late visit, Mr. Ryder introduced to the notice of his visitors a bunch of ladies' finger bananas, on which were counted over eight hundred specimens of the fruit. He also produced a prodigious pineapple, measuring fifteen inches in length, twenty-two inches in girth, and weighing fifteen pounds. Queenslanders are requested to beat that if they can.—*Fiji Times.*

THE rainfall out in Shasta, California, says an American Exchange is in proportion this year to the size of the "big trees" and other big things produced in that State, but its seven feet of rain is less than the average annual rainfall in Bergen, Sweden, only one-half that of Vera Cruz, and only one-third that of the lower slopes of the Himalayas on the eastern side. At Cherra Poonjee, India, more rain falls in each of three months in the year, but that record is hard to beat. Although it does not rain at all during November and December, and less than five inches in three other months, the fall during the year amounts to 608 inches, or over fifty feet.

CAPTAIN PAULI, her Majesty's Consul for Manilla, considering that the geography of the Philippine Islands, and especially their division into provinces, are but little known, has devoted the concluding part of his last report on the trade and commerce of these islands to a succinct sketch of the provinces, &c., illustrating his notes by an outline map. We content ourselves here with merely noting a few of the resources of some of these islands. The interior of the island of Mindoro, we are told, is not explored, but is supposed to contain much mineral wealth, coal, indeed, is known to exist. Its productions are very limited, the only export being cedar, which is used for the manufacture of cigar boxes. Leyte, another island, is volcanic, and its soil is suitable for the production of hemp, of which one-third of the whole production of the Philippines is grown there. In Samnar hemp is grown, and is almost the only production of this island. In the earlier part of his report Consul Pauli gives some statistics respecting Manilla hem p, in regard to which he makes the following remarks :—

"The excellent qualities of this admirable fibre have excited much attention in other countries, and attempts have been made, and are still being made, to cultivate the plant elsewhere, but, it seems, as yet without success. A volcanic soil and peculiar condition of climate are necessary to its development, and only some districts of the Philippines are perfectly adapted to its growth. Its propagation from young shoots, and the difficulty of transporting them with success, together with the slowness of the process, has also been an obstacle. The Indian Government have applied for some seed; but that is very difficult to procure, as the plants are seldom permitted to bear, and seem to deteriorate in the process. The best authorities assert that it is most difficult to grow from seed. Nor would the extended cultivation of the plant be long remunerative, for the Philippine Islands even now nearly meet the demand, and a largely increased production would only tend to lower the price, which frequently leaves but little margin to the growers.

THE *Journal of Applied Science* states that, in consequence of the dearth of grapes for wine-making in France, owing to the *phylloxera*, a large trade has sprung up in the import of dried raisins. In 1879 there were imported into France over 51,000,000 kilogrammes, and in the first six months of 1880, 48,000,000 kilos., so that in eighteen months 99,094,704 kilos of raisins were received from foreign countries. One kilogramme of raisins is sufficient in general for making three litres of wine, so that the total production from this source may be estimated at 2,972,841 hectolitres. The sale of wine made from these raisins at the average of twenty francs the hectolitre, represents the sum of 2,972,841 francs.

THE trees which yield the largest supply of the best quality of caoutchouc, consist of various species of *hevea*, which flourish in the northern districts of South America, especially in the Province of Para, some portions of the valley of the Amazon being crowded to an extraordinary extent with *heveas*. The abundance of the India-rubber trees in Para may be judged of by the fact that this province alone exported seven thousand three hundred and forty tons of caoutchouc in the year 1877, more than half of this being sent to Liverpool.

THE manufacture of cotton oil from the cotton seed, according to the *Times*, is becoming of importance in the United States, there being at the present time upwards of 41 oil mills, of which nine are in Mississippi, nine in Louisiana, eight in Tennessee, six in Texas, four in Arkansas, two in Missourie, two in Alabama, and one in Georgia. The annual quantity of seed converted into oil now amounts to about 410,000 tons, the yield being at the rate of some 35 gallons of oil to the ton of cotton material. Moreover, each ton leaves 750lbs. of oil cake of admirable fattening qualities. A great deal of the cotton oil is imported to Italy and other countries, where the olive oil is a staple; and, in point of fact, cotton oil is there superseding the olive oil, not only for utilitarian purposes, but also as an article of food. It is said, too, that the use of cotton oil in this way is gaining ground in some parts of the States. The following are the statistics of consumption :—

		Export. Gallons.		Home consumption. Gallons.
1876-7	... ...	1,316,000	...	2,000,000
1877-8	... ...	1,457,000	...	1,800,000
1878-9	... ...	5,750,000	...	2,425,000

The cracking of new laid eggs is mentioned among the incidents of the late intense frost.

THE news that paper has been manufactured from grass in England has led a correspondent of the Batavia *Handelsblad* of the 28th January to draw attention to the possibility of making paper from the *lallang* grass, which grows abundantly in Java. On this subject he says :—

"It need not be doubted that very good paper can be made of *lallang*, but it is a problem whether good *writing paper* can be manufactured from it. But it is more than probable and even certain that it can. The fibres of *lallang* at least favour this inference, for they are very fine and silky. The paper made of it will hence be fine and smooth, the qualities preferred in writing paper, especially the latter. Hitherto *lallang* is only used as house roofing, litter for horses, cows, and other domestic animals, and occasionally as fodder for buffaloes and cows in default of grass; and sometimes for manuring land either by itself or mixed with animal manure. In other respects, *lallang* is a product which cultivators would rather not see at all. Whoever shall make paper from it (its possibility is beyond doubt) will make useful, and productive an unimportant grass now covering lagre tracts in Java."

MISCELLANEOUS ITEMS.

NEW England has over two hundred and thirty farmers' clubs, with 72,000 active members, and library books to the number of 21,000; and in the United States, there are two thousand agricultural societies with 58,000 volumes in their libraries, and access to 800 different agricultural publications.

A NEW YORK paper informs us that the leaf of the betel works on the nervous system by calming it, which is proved by the fact that

Orientals, when suffering from headache or nervous pains in the face apply a leaf of betel smeared with cocoanut oil to the affected part, the pain subsiding thereupon. The same journal also says that it may promote digestion, although this has not been proved. What we have heard natives of the Philippines say is that the betel is nutritive, and hat by chewing it they can do without food for several hours longer between their meals."

AT Amsterdam a culture company with a capital of 6,000,000 of guilders and with agencies at Batavia, Samarang, and Surabaya, has been started with the object of bringing money into circulation in Java exclusively for planting purposes, and to provide planters with working capital at low interest. The company's business will be conducted on the principle of lending money rather to solvent persons, than on property.

WE read in the *Japan Weekly Mail* Mr. Mameshima, one of the Committee for Industry at Kamishima Mura in the province of Idzu (Japan), who has for years past given strict attention to agriculture, has lately invented a new method of making paper out of the willow tree; the quality is said to be excellent.

"THE *Locomotief* newspaper, assures us that Netherlands India is the richer by a novel export article. A great firm at Samarang, according to that journal has bought up a large quantity of *lidi* (the mid-rib of the cocoanut leaf, which is used here for making garden and stable brooms), for shipment to America. The object of so doing is said to be to make an experiment on a grand scale in using that material for plaiting baskets, for which it is excellently adapted. Our only fear is that the baskets will cost too dear.

EXPERIMENTS on a sugar estate in the Patti district (Java) have shown the possibility of forthwith using for fuel the crushed cane as wet as when it comes out of the mill. The fire-place apparatus used for the purpose is a new invention supplied by the engineering firm of Van Heumen & Co., at Delft, in Holland.

THE local paper writing of the Lucknow agricultural exhibition a few days before it came off, remarked.—The approaching Agricultural Show has conduced to a widespread dissemination of Exhibition literature. The indefatigable Secretary is publishing papers upon all manner of subjects more or less identified with the agricultural question, and were it possible for the actual Show—as such—to prove a failure, we should still have such a collection of interesting data unearthed that the results would yet be very valuable. Some of the memoranda on oilcake are very interesting. Some very valuable information has been printed on "seed grain sowing" and on "manures;" whilst an important paper on "cattle improvement" is in the press and will be discussed at the Meeting.

IN 1880, the dogs killed 5,369 sheep in Kansas.

A MICHIGAN farmer, in 1880, grew fifty acres of onions.

THE value of poultry and eggs produced in Kansas, in 1880, is given at $531,550.

OLD and experienced farmers in Pike county, Mo., report the wheat crop as safe thus far;

IOWA has some 350 butter and cheese factories, the products of which, for 1880 are estimated at $20,000,000.

IN the north-east of Pike county, Mo., the peach buds are reported as not all killed, plenty remaining to make a good crop.

MADISON county, Ill., grew more wheat than any other county in the State, in 1880, having harvested 3,530,000 bushels.

THE cost of sugar in ordinary house-keeping in the Eastern States, is greater than for flour, greater than for any other article of food, except meats.

AGRICULTURE IN 1880.—We understand that Mr. Henry F. Moore, a well-known agricultural writer, has in the press a small pamphlet, containing a short history of agricultural events in 1880, and also a series of commentary articles on the leading events of the year bearing on agriculture.

PLEURO-PNEUMONIA IN IOWA.—There is hardly any room to doubt that contagious pleuro-pneumonia has at last gained a foothold in one Western State at least, if not in more. Information comes from Bedford, Taylor County, Iowa, that a number of cases of this disease have occurred there.—*Prairie Farmer.*

IT is said that the total amount of butter made in the United States, New York, produces 140,000,000lbs. yearly, and 100,000,000lbs. of cheese.

A LONDON paper points out that foot-and-mouth disease may be spread by men as well as dogs. Yet at Islington and Deptford no note seems to be taken of this fact. The ignoring of the above fact is not peculiar to London.

SELECTIONS.

MR. WEDDERBURN'S AGRICULTURAL BANKS' SCHEME.

MR. WEDDERBURN gives a succinct statement in a recent issue of the *Gazette* as to the prospects of agricultural banks. Capital could be easily obtained at 4 *per cent.* under Government guarantee for the use of which the Dekkan ryot would gladly pay 12 *per cent.* With a central office at Bombay and respectable branch agencies in the mofussil, the bank could work satisfactorily and, of course, independently of existing arrangements. But there are two conditions necessary to the success of the scheme: 1st, the ryot must be freed of his old paper debts; and 2nd, the bank have power to recover the advance from the ryot crop. Mr. Wedderburn's object in proposing the rather heavy rate of 12 *per cent.* is "to create a reserve fund which will be available to assist the bank's clients in tiding over years of scarcity to keep them in their villages, and not to allow them to become *paraganda.*" This is well: only don't kill the ryot by too much kindness say we.—*Indian Spectator.*

AGRICULTURAL CUSTOMS OF THE UMBALLA DISTRICT.

WHEN the sowing season approaches, all the zemindars of the village meet at mid-day, or a *pahar* before day-light, at the *chaupal*, where they are met by the village Brahman, who has brought with him his astrological books.

All Indian agriculturists consider the land to be asleep at certain seasons of the year, and to be awake at other seasons, and the sowing only takes place when it is declared by the village astrologer that the land is awake.

The zemindars also believe that it is unlucky to plough in the month of *Jeth*, and say that this month is *Jati* (holy). Sowing, as a rule, commences in the month of *Asarh* only, but no sowing ever takes place on the 5th, 7th, 9th, 10th, 21st, and 24th of *Asarh*, because on these dates it is said that the land is sleeping, and therefore seed sown then will either prove a failure or will not yield much produce.

The Brahman announces the auspicious day for sowing. When they go to sow, if they should meet a widow with a bald head, they return to their homes as the omen is bad. Likewise if they hear outside the village on the left hand side the call of a partridge, or the howling of a jackal, they postpone the sowing for that day; but if, they hear the call of a partridge, or the howling of a jackal, on the right hand side, or in front of them, it is regarded as a good sign.

The call of a *koil*, or the Indian cuckoo, is always considered very lucky.

When the zemindars go to their fields to sow, they tie pieces of red thread called *mauli* or *pâranla* to their right wrists, to the horns of their plough bullocks, to the ploughs, and to the yokes, and touching the ploughshares and the bullocks with pieces of *gur*, and putting some of the *gur* in their own mouths, commence to plough their fields.

The Brahman receives on that day, by way of charity, a seer or two of grain for every plough. The zemindars partake of *dalia*, or sweet-rice, and give some of it to their ploughmen.

The harrow is also worshipped. The zemindars go into the field with seven leaves of the *akh* (*asclepias gigantea*) which they place on the harrow, and on the leaves some parched rice and sugar (*gulyah*), and burn incense. This is known as the *sohaga ka puja*.

They first sow as an omen of good promise, seven kinds of grain called *satndja* in one spot, in a corner of the field; and this sowing is technically styled the *halota*. They always carry the seed for the general sowing in a *jholi* or bag, and while sowing they keep repeating a prayer that by the blessing of travellers, of birds, and of beasts, the produce of their fields may be abundant.

They give in charity from the same store to such beggars as come and ask for charity, as also they give some of it to their herdsmen who take care of their cattle, when they sow wheat for the *rabi* harvest. After the sowing they boil the surplus seed. The boiled wheat is called *bakhian*, which is distributed to all those present, who eat of it plentifully, praying to the goddess Sif (Lakshmi) to bless their labors.

On the night of the *sâir*, or the night of the *sankrânt* of the month of *Asoj*, a clear sky is believed to be a good sign for all *kharif* crops; and in the hilly tracts of this district the zemindars have public worship on such a night with singing and general rejoicing.

No particular ceremonies are observed while the crops are growing. When the crops are ripe and ready for the sickle, first a load of every kind of grain is cut and brought home; and after it has been offered to the household gods, the grain which is called *puchkani* is distributed to the Brahman and to beggars in charity. After the performance of this ceremony the general reaping takes place, which is usually on a Tuesday or a Wednesday. The reapers are called *áwa*, and receive half a load of grain each per diem as wages. After reaping, the women of the village servants are allowed to glean in the fields. These gleaners are called *sithari*.

The sheaves are then brought to the threshing floor, and bullocks are yoked (*gah jorke*) to tread them.

When wheat and grain are being trodden by bullocks, all the dung dropped by the animals is allowed to accumulate on the threshing floor, as long as the threshing continues. They believe it is unlucky to remove it, nor do the men guarding the grain sleep in the threshing floor on *charpois*.

After the sheaves have been sufficiently trodden by the bullocks, they winnow the grain with the *chhaj* or winnowing basket and the *tangli* or winnowing fork, and never in the day time, but only in the first or last watch of the night: they collect the grain in one large heap with a *chhaj* called *chang*. The person who uses this *chhaj*, must strike the heap thrice each time before he draws a fresh breath so long as he is occupied with the work. They then draw a line, called *kar* round the threshing floor, and pouring a mixture of oil and butter, they place a jar of water within this circle to guard the grain from evil spirits.

They take a *chhaj* and top the heap of grain with the edge of the *chhaj*. They then take some fresh cowdung, and placing on the top of the heap some fresh green grass, they deposit the cowdung on the grass, sticking into it also a ploughshare or reaping hook. They now burn some incense on cowdung fire, and, kneel and sopray before the heap, and after distributing some *gur* among those present, they put aside from the heap some grain

which they make into three of seven little heaps, called *sauri*. Brahman's, and mullahs, and sweepers get this grain, as it is considered to be the share of the gods and of *sesnag*.

Next they bring an earthen vessel called a *nep* to which is attached a piece of red thread. They measure the grain with this vessel.

They do not speak in a loud voice during the progress of these ceremonies, and will not permit any noise; profound silence particularly being maintained while the grain is measured with the *nep*. Any excess less than the last measureful is distributed in charity to the village servants. They now begin to converse with one another, and the grain is carried home, weighed and stored. When the grain is storied in bins, the bins are leeped with cowdung; and the owners stand before their bins with their hands folded, and pray for a blessing.

As regards storing in pits, it should be stated that only the produce of the *rabi* is so stored. The produce of the *kharif* is seldom or never stored in pits. Indeed, as a rule, zemindárs do not store their grain in pits, except when they happen to be large landed proprietors, and have more grain than they can readily dispose of; banais however constantly do so.

When a pit is about to be dug, some oil is poured on the site, and *gur* is distributed. The pit has first a layer of *bhusá* deposited at the bottom, and the sides are lined with mats and *dhak* (*butea frondosa*) leaves. Some *bhusa* is inserted between the lining and the sides to keep out the damp. When the pit is filled, the mouth is closed first with mats and then with mud.

Cotton seeds are smeared with cowdung before sowing. Before commencing to pick cotton, women generally being engaged to do the work, two of the women put a little parched rice (*khilán* or white uncooked rice and white *til* seeds in their mouths, and one running on one side of the field, and the other running on the opposite side, without crushing the grain in their mouths, spit out the grains and scatter them all over the fields. This scattering is called *bari phurakana* or *kapas ka phurakna*. This is done with the object of getting white cotton, and with the hope that the yield will be abundant, and the seeds preserved from the ravages of insects.

All the cotton picked by the women on the first day is not carried home, but is taken to the bazaar and sold, and *gur* is bought from the proceeds, which the women eat and distribute among themselves.

Sugarcane is sown on a Wednesday or a Saturday, or Sunday. On that particular day the women of the family of the zemindar do not spin cotton, so that the canes may not be stringy; and on that day they tie to the arms of the ploughmen and to the plough, red thread and distribute *gur* among their friends, and indeed smear the plough with *gur*. The men after eating the *gur* bless the field, and pray that it may produce good canes. On that day rice is cooked at home and the rice water is poured from the roof of the house down the water spout, with the hope that the canes will be full of juice, and that the juice will pour like abundant rain into the sugar mill. Sometimes they add sugar to some of the rice water and drink it. The rice is eaten by the zemindars mixed with curds before they go to sow.

After the canes are ready for the mill, arrangements are made to crush the canes. The proprietor brings some rice and *til* seeds and sugar mixed together called *tilbakhera*, to the field; and takes a load of 8 or 10 canes and ties them up with red thread, the load having the name of *merha*. And he fumigates this *merha* with incense and offers up the *tilbaknera* and *merah* to a divinity called *Mukal*,* or the patron god of the sugar mill, invoking him by name.

The work of cutting the canes now begins. First, after a load of cane has been cut, the *tilbakhera* is distributed among those present, and their fervent prayers are that from each *kachcha beegah* of canes (about an eighth of an acre) not less than a *bari* (or 24 hours' continuous crushing) of cane juice may be produced.

Then, one or two more cartloads of canes are cut and on the right side of the mill, an excavation in the earth of a cubit long and a cubit deep, is made which is leeped inside and outside with cowdung. This excavation is sacred to *Mukal*: in fact the excavation itself is commonly called *Mukal*.

A hole is now dug for the mill. In this hole a cane is broken up and thrown in, and five canes are similarly broken up and thrown into the excavation sacred to *Mukal*. The mill is then sunk in the hole made for it. The mill is set to work, and the canes are to be crushed. After one or two loads of canes have been crushed, some of the juice is first poured into the place of *Mukal* and the rest is offered up in the names of the ancestors of the proprietor, and to his household gods, and afterwards distributed to brahmins. Mohamedan zemindars distribute the juice to faquirs. This rite is known as *raspohon*.

When the *gur*, *shakur*, or treacle is first prepared, the man who prepares it takes half a *kutcha* seer (three chattack) and drops it into the excavation sacred to Mukal, and the proprietor takes one or two *bheli*, or lumps of about three seers each, and places it before this sacred place and prays to *Mukal* for abundance of produce. The fireman takes about six chattacks for himself, and the rest is divided among the other persons employed in the work.

After this the mill is worked without further interruption for religious observances.

They also sink near the mill an earthen or wooden vessel which is capable of containing four maunds of cane juice. This is called *baha*. Whenever the *baha* is quite full, five *kutcha* seers of juice is given to the bullocks which turn the mill.

J. G. DELMERICK,

in Roman Urdo Journal.

ARTIFICIAL INDIGO.

We learn from Munich that "Artificial Indigo equal to Indian, has been discovered there by a scientific man." This is not by any means the first time that an announcement of this kind has been made, and has caused some alarm in Mincing-lane and elsewhere. But the artificial product of the laboratory has as yet failed to meet the requirements of manufacturers. Yet it is always "on the cards" that some chemist will invent a perfect substitute for the Indian dye, and thereby be instrumental in ruining a very important industry in this country. The following table shews the quantities and value of indigo exported from India in ten years:—

Year.	Quantity. cwt.	Value. £	Year.	Quantity. cwt.	Value. £
1869	99,205	2,893,823	1874	115,980	3,555,300
1870	98,085	3,178,045	1875	81,466	2,678,392
1871	108,184	3,192,508	1876	110,392	3,875,065
1872	115,414	3,705,475	1877	100,384	2,862,766
1873	115,212	3,426,824	1878	120,605	3,494,334

We are indebted to Chamber's Encyclopædia for the following remarks:—

"This dye is, without doubt, the oldest in use; the Greeks and Romans obtained a knowledge of its uses from India, where its employment has been very general for a great length of time. Much obscurity involves indigo and its early use in consequence of the variation in its name; for instance, the Tamils of India call the plant *Averie*, and the dye itself *Neelum*; in Sanscrit, the plant is *Vishashodanie*, and the dye *Nili* and *Nilini*, whence the *Anil* of the Portuguese. The Malays call the dye, *Tarom*, and the Arabs, *Neel*. Commercially speaking, indigo may be said to be the produce of India and Central America, as these are the only localities which supply the recognised form of the article. In India, the chief seat of the indigo manufacture, Bengal is the most important district. The total quantity received in Great Britain in 1861 was nearly 80,000 cwt—a vast quantity when it is borne in mind with what difficulty it is cultivated and manufactured. When pure indigo has a rich, dark-blue colour almost purple, it is in small cubes or parts of cubes, and its fracture shows a tendency to break up into square pieces and indicates cracks in its substance, often filled up with a film of whitish efflorescence, probably the lime used in precipitating it. It has neither taste nor smell, and its specific gravity is about 1·50; if rubbed with any hard substance, it gives a streak with a bright coppery lustre. The varieties recognised in commerce are—1st, Bengal, which from the care taken in its preparation, and the large scale on which it is made in that district, is the best; and its various gradations of quality, ten in number, varying from 9*s*. to 5*s*. per pound, are always kept distinct. In other sorts, they are usually much mixed. 2nd. Madras and Kurpah; 3rd. Oude; 4th, Manilla; 5th, Java; and 6th, South American. The last is packed in serons or cases of dried ox-skin, and its qualities are distinguished as follows: 1st, Flores; 2nd, Sobres, and 3rd, Cortes; all the others are in wooden chests, containing about 250 lbs. each. Few materials are of greater importance to the dyer than indigo, and none require the exercise of more care and skill in using. Being insoluble in water, it requires the action of other solvents to render it capable of penetrating the fibres of the materials to be dyed. Many compounds of great chemical interest have been derived from indigo blue. It was from indigo that aniline (now so largely employed in the production of the pigments known as *mauve* and *magenta*) was first obtained."—*Madras Mail.*

THE AGRICULTURAL VALUE OF HOUSE SEWAGE.

The Government having asked for information as to "whether any practical results have attended the efforts of the Collector of Tinnevelly to impress upon the people the agricultural value of house sewage," Mr. Pennington has reported to the Board of Revenue that he was under the impression that a report would only be necessary when some material progress had been made. "On receipt of the Government Order, I communicated it to the several Divisional Officers and the Vice-Presidents of the Municipalities and invited their particular attention to the subject in view to the people being induced to utilize house sewage, &c., in the manner already pointed out. The Commissioners of the Palamcottah Municipality say that the 'question has had no practical results' in their Municipality 'for the simple reason that hardly anything worth the name of sewage exists. The town being built on a natural slope, the drainage is carried off at every shower of rain towards the existing natural receptacles, viz., the channel, the river, and the fields, then and there, and thus no opportunity is afforded for any large accummulation anywhere.' This system of storing and selling night-soil, &c., is however, being improved and perfected gradually, and the people are generally careful of the contents of their privies and utilize everything as manure. The Vice-President of Tinnevelly Municipality reports 'the residents of this town have all along been careful in collecting the house rubbish and the night-soil of their private privies for the purpose of agricultural manure, so much so that they would not allow the Municipal toties to clean their privies and remove the filth from their back yards. Even those who have no lands of their own heap them up for the purpose of sale. All that the Commissioners were able to do last year has been to give wide publicity to the advantage of the dry earth system; and with a view to initiate the people into that system, they have also opened a dry earth depôt near the Municipal Office and employed four toties to distribute dry earth amongst the several house owners for being used in their privies.' What is still wanting is to avoid the waste of fertilising matter all round the towns and in the roads, and the consequent nuisance that prevails so extensively, and also to improve the management of private privies."

GENERAL INTERFERENCE WITH PRIVATE ENTERPRISE.

The system under which Government undertakes the nursing of new industries seems to require remodelling. In the matter of tea, everything has been done in accordance with the principles of common sense. It is true a mistake was made in the introduction of a trashy variety of plant from China, but considering the amount of information at the disposal of the Government in the early days of the industry, we feel convinced that impartial historians will give it much credit for what it did. In connexion with cinchona, on the other hand, we think a mistake is being made. The profitable cultivation of that valuable plant has now been placed beyond the reach of doubt, and the industry may be said to have long passed beyond the experimental stage. Such being the case, the Government should before this have receded from the business, and disposed of its plantations, thus leaving the industry to the care of private enterprise. There can be no doubt that capital would readily be found to take up and carry on the work.

Another industry has lately been initiated by the Government,—that of growing tobacco, and preparing the same for the consumption of Europeans. In connextion with this, neither of the two former plans has been followed. The Government has, in some extraordinary fashion, leased the farm to an enterprising firm. If the experiment was a success, the Government should at once have retired from the business. On the other hand, if success had

* Literally, creator of sweets. He is the god of sugar and of fish, and was the son of Brij Arjun, and the grandson of Paras Ram, the sixth Avatár of Vishnu.

not followed its efforts, it was equally bound to give the business up, leaving the commercial public to form their own opinion as to the causes of the failure. That success followed the experiment no one who has studied the subject can doubt. There are few crops grown in India which give such a good return as tobacco, perhaps none, cinchona alone excepted. Under these circumstances, there should have been no difficulty in disposing of the property. The negotiations at present pending in regard to the latest experiment of this kind, in connexion with silk, seem to point to the imminent adoption of a similar course. We learn that "it has been decided by Sir George Couper that the management of the sericulture operations in these provinces (N.-W. P.) shall for the future be entirely made over to Messrs. Lister & Co., an eminent silk firm of Bradford, in England, on certain terms which have not yet transpired." These last eight words would seem to point out to a lease, or a conditional sale, neither of which is in accord with the principles Government ought to follow in such matters.

Having relinquished the experiment, Government should dispose of the whole concern to the best advantage, and put the public in possession of the information it possesses, and the experience it has gained.

In respect of tobacco, no benefit of a commercial nature has yet accrued to the general public from the few years' trials made by the Government of the North-Western Provinces and Oudh. The whole concern has been made over to a private firm, whose interest naturally lies in the direction of secresy. Had the farm been sold to the firm, this would have been perfectly in order, but its only being leased to them points to the fact that the farm is stil Government property, while this particular farm is the only one in a position to derive any benefit from the expenditure of public money incurred in the experimental stage. It is true that Mr. Buck in 1878 published a pamphlet giving details of what had been done, but at that date sufficient time had not been given to the subject, and the conclusions arrived at were naturally crude and incorrect. For instance, we are told "that the outturn of good leaf from a properly cultivated acre of land ought not to be less than 800lbs" This is misleading and might do much injury, by preventing investors or cultivators from taking up the industry. The average outturn of tobacco in the Punjab in the two years 1877-78 and 1878-79 was 787lbs. per acre If, then, this was the average under ordinary native cultivation we have no hesitation in saying that "the outturn of good leaf from a properly cultivated acre of land" should be very much more than 800lbs. We are convinced that on good land, such as tobacco ought to have, over a ton ought to be the average. Good tobacco, well grown and carefully cured, may safely be expected to realise two annas per lb, at least. This has no reference to the ordinary native cured tobacco, but to that cured under scientific supervision, and adapted to European use, in open market. At a ton per acre, this represents an income of Rs. 280; while the expenditure is comparatively trifling. We mention two annas per lb, but if any one tries to purchase thoroughly well cured tobacco, fit to make good cheroots for European consumption, he will find it cost much more than this.

Tobacco is now receiving considerable attention at the hands of those in a position to judge its merits properly, and we look on it as one of the most promising industries calling for our attention at the present day. —*Englishman.*

INLAND TRADE OF BRITISH BURMA.

FROM the Official Report on Inland Trade, British Burmah, for the year 1879-80, it appears that the only monopolies now retained by the King of Burmah on the trade of the Irrawaddy river, are those of petroleum and pickled tea (*let-pet*). The *oil-wells* of Upper Burmah are exculsively in the hands of a native of India, one Moolla Ibrahim, who sent down 108,511 maunds, value £61,448, during the year, against 78,019 maunds, value £35,632, in 1878-79. When the British Resident was withdrawn from Mandalay in October 1879, the monopolist fearing complications, sent all his stock across the frontier into our territory where, it is said, a good deal of it still remains unsold. The oil is sold through agents in our towns, but meets with strong competition in the American kerosine oil imported at Rangoon. The monopoly of the trade in *pickled tea* was in the hands of the Royal Steersman, who pays the King a large monthly sum for the privilege of being the sole vendor, and all the makers of *let-pet* are obliged to sell their stocks to him. He has agents in the various towns, and fixes his own price. This is said to be so high that the humbler classes of the Burmese have been obliged to forego the use of *let-pet* altogether, and hence arose a very great reduction in the imports, which fell from 29,009 maunds, value £54,008, to 11,880 maunds, value £24,746. Why do not the Indian tea-planters, who are hard up for a market, make some pickled-tea and cut out the Royal Steersman? A small quantity is already imported *vià* Toungoo. There is a large and increasing demand in British territories for the *ponies* which are brought across the Thyetmyo frontier for sale, but the trade is cramped by the rule of the Burmese Government, which forbids the export or either stallions or mares. The stock imported consists solely of geldings, which fetch prices averaging from £10 to £15 in Rangoon. A considerable and steady trade is done in *lacquered ware, drinking cups,* &c., and also in *metal* manufactures, such as idols, bells, gongs, pagoda-crowns, &c. The trade in *jadestone* is in the hands of the Chinese, who export large quantities to their own country: prices vary continually. The *tobacco* produced in Upper Burmah is not in favour, consumers preferring that which is grown in our territory.

The principal articles of export to Upper Burma are cotton twist, yarn, and piece goods, European tinned provisions salt, &c. A large business in cheap English crockery is done with Upper Burmah, the trade being in the hands of Burmese and Chinese, who have agents in all the river stations. Lacquered trays and platters are rapidly being replaced by these goods, which are making their way into every household. According to the returns the trade doubled itself in the year under report. The trade in metal manufactures has increased, owing, it is said, to the Mandalay lotteries having diverted the attention of the people from the native industry." For the same reason there has been a large increase in the trade in English silk piece-goods, and the excellent harvest of the year has given several exports an additional impulse. The local manufacture of salt is rapidly declining, and European salt, of which a great deal now reaches Rangoon annually, is everywhere taking its place.

POPULATION OF ENGLAND AND WALES.

A PAPER "On the Increase of Population in England and Wales," was read by Mr. R. Price Williams on the 15th ult., before the Statistical Society, in which he pointed out that the total increase of the population of England and Wales during the whole of the last century, was only 3,417,536, the average decennial rate of increase being 5 per cent.—whereas during the present century, up to 1871, there was an increase of nearly 14 millions, the average decennial rate of increase being over 14 per cent. The rate of increase in the decade 1811-21, was the maximum attained in this century, viz., 18 per cent., as from that period down to the census of 1861, the rate of increase of the population had continuously diminished. He observed that a great increase of the population took place at the time when steam power began to be used for manufacturing purposes, and while the towns increased, the rural districts were found to diminish Mr. Williams estimates that the population of England and Wales, by the census of 1881, will be 25,785,900. In the case of the population of London, the decrements were very slight indeed, showing that it had not reached that declining stage in the rate of its increase long since arrived at in the case of Liverpool, Manchester, and many other large towns. The population of London had increased from 958,863 in 1801, to 3,251,913 in 1871.

THE WOOLLEN INDUSTRY.

THERE are few things more remarkable than the growth of the woollen industry of the world during the present century; and this growth which has been most marked since 1830, is mainly due to the extension of our own colonies and the development of the United States. The wool clip of the world has increased by five times since 1830, when it was equal to about 320,000,0000 lbs. while in 1878—the latest year we have complete figures for—it amounted to nearly 1,600,000,000 lbs., which when scoured, gives 850,000,000lbs. of clean wool. Previous to 1830, nearly all the world's supply of wool was furnished by Europe; 280,000,000lbs., out of the entire world's supply of 320,000,000 lbs., being European :—

		1830.		1878.
European produce	...	280,000,000 lbs.	...	740,000,000 lbs.
River Plate ...	...	22 000,000 lbs.	...	240,000,000 lbs.
United States ...	...	10,000,000 lbs.	...	208 000,000 lbs.
Australia ...	...	6,000,000 lbs.	...	350,000,000 lbs.
South Africa ...	...	2,000,000 lbs.	...	48,000,000 lbs.
		320,000,000 lbs.	...	1,586,000,000 lbs.

The tendency is to increase and improve the production of wool by improving breeds, by careful management, by improvements and cleansing the wool of the sheep before clipping, as well as by improved machinery for washing and scouring fleeces after having been clipped and sorted. It would be interesting to show the total number of persons engaged in the woollen industry of the world, as far as operatives are concerned. We have a fair idea of the numbers, although the manufacturers of wool and cotton fabrics represent an almost equal amount in value, the number of operatives in woolen mills is only two-thirds of that engaged in cotton mills :—

		Operatives.		Spindles.		Consumption.
Great Britain	...	280,000	...	5,100,000	...	380,000,000 lbs.
France ...	...	170,000	...	2,500,000	...	380,000,000 lbs.
Germany ...	...	120,000	...	1,800,000	...	165,000,000 lbs.
United States	...	120,000	...	1,400,000	...	250,000,000 lbs.
Russia, Austria, &c.	...	223,000	...	1,800,000	...	400,000,000 lbs.
		913,000		12,600,000		155,000,000 lbs.

Although France and Great Britain consume the same quantity of wool, in France it is to a greater extent the unscoured wool of the River Plate, which only turns out 30 per cent. of wool, whereas in England, it is native or washed Australian which is mainly used; hence the woollen manufactories in Great Britain are considerably greater than in France, although the pounds weight consumed would appear to be the same.—*Wool.*

FIELD EXPERIMENTS ON SWEDES.

MR. JOHN HILL, President of the Marshbrook Agricultural Improvement Society, has favoured us with an account of a series of experiments carried out at Felhampton Court, Shropshire :—

The soil may be described as a moderately good turnip and barley soil, lying on the Caradoc or Bala beds, with a deposit of clay and drift gravel in patches, and partly mixed. The experimental plots were all situated side by side on a portion of the field which was of very equal staple throughout. They were one acre in extent—were sown on the 1st of May, on the flat, the manure being sown by the drill in a line under the seed, and the drills were 24in. apart. There was no rain during the sowing, but on the 10th of May there was a slight rain, and on the 26th of May there was a heavy soak The swedes were all hoed during the first fortnight in June. The following is a statement of the manures sown and the weights produced :—

Plot.	Manure sown per acre.	Cost per acre.	Produce per acre.	Remarks.
		S.	T. C.	
1	5 cwt. superphosphate ...	20	26 17½	
2	5 cwt. redonda phosphate, 2½ cwt. superphosphate	30	25 0	Rather damaged by fly.
3	2½ cwt. superphosphate, 119 lbs. bone meal ...	20	25 1½	
4	5 cwt. superphosphate. 108lbs. sulphate of ammonia ..	40	23 17½	Rather damaged by fly.
5	2½ cwt. superphosphate, 2½ cwt. redonda phosphate ...	20	26 0	
6	No manure ...	...	7 6½	
7	5 cwt. redonda phosphate	20	30 0	Much choked by charlock.

The striking contrast observable between the results from each variety of manure used, in comparison with the produce of the land where no manure was used, is well worthy of special notice. The smallest increase in the weight of swedes produced by the artificial manure used was in the case of the superphosphate and sulphate of ammonia; here an increase of 15 tons 11 cwt was obtained at a cost of 40*s*. The largest increase was obtained from the use of the redonda phosphate, simply ground to a very fine powder; here an increase of 22 tons 13½ cwt was obtained at a cost of 20*s*. It appeared to be very important that we should extend the inquiry so as to form an opinion as to the feeding character and composition of the swedes produced. So far as regards this series of experiments, No. 7 lot which was manured with 5 cwt of redonda phosphate per acre—at a cost of 20*s*. per acre gave the largest weight per acre (30 tons); the roots were the heaviest in water, they were also by analysis shown to be the best in feeding quality. The smallest crop of swedes was that grown with superphosphate and sulphate of ammonia, *at double the cost* per acre for manure; these roots were lightest in weight, and the lowest in their feeding power. Although it is not safe to be entirely guided by a single series of experiments, there does appear to be good evidence before us in reference to the inquiries which were being dealt with. As to the first inquiry, whether the phosphate should be used in an entirely soluble condition, as in superphosphate, the reply given is more adverse to its use than I had expected. On the second inquiry, I may say we have obtained most encouraging and satisfactory results from the use of the redonda phosphate, simply ground, and without any chemical treatment. Then as to the third inquiry, respecting the advantages of a supply of ammonia, there has been not only no advantage gained by a double outlay for the purchase of this manure, but the quality has been rendered very inferior by the ammonia, and the weight of the crop has also been decreased by its presence.—*N. B. Agriculture.*

LIME AS A MANURE.

THE very abundant and highly important substance popularly called lime, but dignified by chemists with the name of *protoxide of calcium*, has long been used by agricultural nations as a manure. It has been in use for nearly 2,000 years, for, according to Pliny, the Gauls successfully raised heavy crops of corn with it; while the Romans found an application of lime very beneficial to their vines and olives. It was, however, about the middle of last century before liming was introduced into this country.

The reason why lime acts so powerfully on vegetation is that combined with decayed animal and vegetable matter, it forms into a compound soluble, which, melting by the action of rain, supplies the plants with the chief elements of vegetable life—oxygen, hydrogen, and carbon; while it at the same time attracts carbonic acid from the atmosphere and forces the plant to absorb those gases more rapidly than usual.

Lime is found to be more efficacious upon—1. Land that has been habitually lightly manured than upon land that has been habitually heavily manured. 2. Land that in its composition contains no alkali than upon land which does contain alkali. 3. Land containing lime in its composition which has been habitually ploughed deeply than upon land in a similar state habitually ploughed lightly. 4. Newly broken up old grass land than upon land which has been previously continually cropped.

Lime ought not to be applied at all to lands which, according to their nature, already contain any of it in their composition; neither ought it to be applied to soil, no matter how rich that soil may be in other manures, as long as the remains of any previous application continue to exist therein. It is well known that lime from its nature, always seeks down into the ground; and it is also well known that some soils retain its influence longer than others. According to one authority, twenty years is supposed to be the limit of its beneficial action over a great part of the south of Scotland; while another, a farmer in one of the Border counties, after laying down and liming a field of grass, found its influence extended to nearly thirty years.

Soils which spontaneously produce the cow-wheat, the colt's-foot, thistles, or poppies, and which have little spontaneous growth of grasses, also land which after a drought crumbles away with the first rain, may safely be cultivated without the use of lime; while, on the other hand, that which has a cold, wet, sandy surface, with a stiff clayey subsoil, and which grows luxuriantly the chestnut tree, the larch, or the Scotch pine, is almost destitute of calcareous substances and would receive much benefit by a liberal application of alkali. Dr. Sheier, an agricultural chemist and a great authority on such matters, says :—'In Scotland we often hear of soils which have been scorched with lime. Such land grows green crops and grass well enough, but not grain crops. The cases of this kind which have come under my observation are chiefly thin soils, naturally deficient in lime. It appears in such cases to be the result of overcropping immediately preceding the application.' All the manure in the land having previously been exhausted, the lime having nothing to work upon, of course could have no other effect than to burn the crop; the mistake lies in the fact that it is regarded as a nutriment, and that crops will grow on it and nothing else. After farming away until all the animal and vegetable substances in the soil are exhausted, the farmer doses his land with lime, and upon finding that a dry season burns up patches here and there over the whole field, cries out that lime doesn't pay. We couldn't live without salt, yet, put a man upon salt and nothing else, and see what will become of him; the same with land, give it lime and nothing else, and it will soon become in a worse state than it was in at first.

Lime greatly accelerates both the dissipation of manure and the chemical decomposition of the soil; and in the very degree in which it increases fertility by this species of action, the land on which it operates must, in order to maintain the fertility, be supplied with proportionally large doses of manure, and perhaps with occasional doses of such mineral constituents as combine chemically and nutriently with the lime. Grass lands which have been allowed to run to seed, and which have become overrun with rushes and coarse vegetation, may be greatly improved by a dose of quick lime; for, according to Dr. Hunter, 'Quick lime is an instrument of death to the coarse herbage of meadows.' The same authority says that it is also known to change the taste of certain kinds of grasses altogether. 'If a handful of lime be thrown on a tuft of rank sour grass, which has in former years been invariably refused by cattle, they will afterwards eat it close down.' Fine pasture lands have likewise been found to be materially benefited by a top-dressing of the mineral in a mild form.

The scourings of ditches, the sediments of mill-dams, &c., together with road scrapings and rack, in fact any kind of rubbish or decomposed vegetable matter, may advantageously be formed into a lime compost. But although the celebrated chemist, M. Pouvis, eloquently sings the praises of such composts :—'Lime in compost is never injurious to the soil; it carries with it the surplus of alimentary manure which the surplus of product demands for its sustenance; light soils, sandy or gravelly, are never tired by a repetition of this compound,'—a judicious farmer may find them everything such as M. Pouvis describes; but, on the other hand, one who does not know their nature may impoverish his land by their use. In fact, composts are so deficient in ammonia and phosphorus that they ought always to be used along with either bone dust, guano, or else ordinary farmyard manure; they ought never to be used alone.

Farmers ought to look well to the quality of the lime which they purchase. 'I have seen,' says Dr. Hunter, 'farmers not unfrequently driving home a thousand cartloads of what they thought was lime; all the time they were unknowingly bestowing their money on a disguised substance, half of which was sand or clay.' Pure lime is commonly white, and is thoroughly soluble in nitric acid; it is also the best which is the whitest, the softest, and the lightest.

Now, when the old days of farming are passing away, in which, according to a seventeenth century writer, 'rains and dews, cold and dry winters, with stores of snow, I reckon to be the best kinds of manures, impregnated as they are with celestial nitres,' I cannot conclude better than in the words of Liebig :—'A time will come when plants growing in a field, will be supplied with their appropriate manures prepared in chemical factories, and when plants will receive only such substances as actually serve them as food.'—*David Swan, in N. B. Agriculture.*

QUANTITY OF GUANO AVAILABLE.

IT is roughly estimated that the nitrate beds of Peru contain about 60 millions of tons. Those of Bolivia, thus far known, are, although large, inferior in extent to the neighbouring ones in Peru. In Northern Chili some 8,000 tons per annum are exported from deposits already reported. It is not improbable that extensive nitrate deposits may yet be found in Argentine Patagonia, able to compete with those of Peru. In 1878 the estimated tonnage of the southern deposits of guano was as follows :—

				Tons.
Huanillas	...	...	...	1,000,000
Point Lobos	...	...	...	200,000
Pabellon De Pica	...	...	...	350,000
Chipauabay	...	...	...	250,000
Add for the Lobos Islands		...	...	600,000
Total	...	...	...	2,400,000

Other deposits of great extent have been reported, but their cubic contents and market value are doubtful. The average annual consumption of Peruvian guano during the ten years from 1869 to 1878 inclusive, was about 345,000 tons. The consumption of nitrate by the North Atlantic nations is shown by the following table of Peruvian shipments :—

				Tons.					Tons.
1866	...	...	...	99,440	1873	...	...	...	284,715
1867	...	...	...	115,925	1874	...	...	...	252,783
1868	...	...	...	86,659	1875	...	...	...	326,[illegible]

—*South American Journal.*

PERSIAN OPIUM IN CHINA.

VARIOUS notes lately written by the English Consul in China show how the consumption of Indian opium in that country is affected, first, by the trade in Persian opium, and, secondly, by the cultivation of the plant in China itself. Persian opium is rarely smoked by itself, being used by the Chinese to adulterate Malwa or the better classes of home-grown opium. It is much inferior to the Malwa kind; but it has this advantage, that while Malwa opium pays an export duty of Rs. 750 per chest, Persian opium is exported free of any tax, "thus showing," says her Majesty's Consul at Foochow, "the extent to which it can damage the prospects of the Indian drug, the more so when it is considered how much less it costs to produce Persian drug in Persia, than Malwa in India, owing to the inferiority of the former kind." Hence it is, Mr. Sinclair adds, that the profits of Persian traders are enormous, and this again has encouraged the extension of the area of opium cultivation in Persia. With regard to opium grown in China, Mr. Herbert [illegible], her Majesty's Consul at Kiukiang, writes that within the last three years there has sprung up a fair demand, which is likely to increase, for opium grown in the province of Szechuen. Chinamen who are well off, and can afford to be particular, smoke Malwa opium; but the majority of the country people and fishermen living along the banks of the Yangtsze have to content themselves with a cheaper article, and they use the Szechuen opium mixed with a small [illegible] of the Persian drug. The [illegible] curious comment on the [illegible] made by the Chinese Ambassador

in England to obtain an expression of popular feeling against the immorality of the Indian opium revenue. The facts about the import of Persian opium into China, show that Persia is quite ready to make up for any falling-off in the supply from India.

THE annual report on Horse-breeding Operations in the Punjab for the year 1879-80 again presents the picture, not exactly of the just man struggling with adversity, but, what is almost as affecting, of the zealous departmentalist chafing against financial restrictions. Mr. Hallen reiterates so urgently the necessities of his establishment that an obdurate Government might well be moved to fall in with his desires, were it not that, unfortunately, his figures attest the most favourable results under the existing provisions. In such an even course of prosperity, in fact, as the report records, it is difficult to find room for remark. One of the most noticeable features connected with the subject is the rapidity with which the Punjab is outstripping the North-West Provinces as the horse-breeding province of India. Whereas in the previous year the number of stud branded mares in each was nearly as possible the same, or in round numbers 3,750, in that under review the Punjab shows over 5,000, the North-West 3,859; and this in spite of the drain caused by the war, which fell most heavily on the frontier province. In the matter of breeding, the Norfolk Trotters continue to hold the first place as sires, their progeny being more strongly built than that of the English thoroughbred, and larger than that of the Arab. But the difficulty of getting exact particulars of the stock is one of the chief complaints of the department, who in the absence of any means of personal inspection are obliged to go by the popularity of the different classes with the native breeders. Mr. Hallen recommends the purchase also of country-bred sires for the purposes of the department, but the Government are not persuaded that the indigenous breeds have not improved sufficiently to warrant this departure. The report shows also that mule-breeding is no less certainly on the increase, the demand for these animals having received a great impetus during the late war. There are several reasons why mule-breeding should be profitable, and its usefulness is universally admitted. The announcement that it is about to be introduced systematically into the Central Provinces generally acceptable.—*Pioneer*.

A NATIVE paper gives the following statistics:—The exports of silk in Yokohama from June 1879 to the same month in 1880, were 17,822 bales; of which 4,406 was despatched for England; 8 194 for France; and 5,222 for America. During the same period the arrivals of that staple to Yokohama from producing districts were 31,034 bales. Exports from July last year up to the 28th January this year were 14,155 bales; of which 1,734 were for England, 8,642 for France, and 3,779 for America; and the arrivals from producing districts to Yokohama in the corresponding period were 27,714 bales The present stock in Yokohama is 6 618 bales composed as follows:—Hanks 2,283, filatures 2,597, Kakedas, 1,235, Okusen 168, and Hamatsuki 330 bales.

THE LONGEVITY OF THE ORANGE TREE.

AT a meeting on the 4th December, of the Adelaide Gardeners' Improvement Society, the longevity of the orange tree, which had been previously discussed, was again brought up for consideration. The following report of the discussion is given in *The Garden and the Field*:—

Mr. J. F. Pascoe said that in view of the great importance of the cultivation of the citrus tribes in this colony there need be no apology made for dealing with the matter at considerable length There were large areas now being cultivated with oranges, and we were beginning to export the fruit, which was acknowledged to be of superior quality. In Sydney our oranges had obtained a special first prize, whilst the Sydney-grown fruit had only been awarded an ordinary prize. If the orange trees would only live for the short period assigned to them in this colony, viz., about 20 to 25 years, it would not pay, for during the first five years the trees bore no fruit; during the next five they produced very little; and, if during the next 10 or 15 years they bore abundantly, the crops would scarcely recompense for the long peirod of unproductive cultivation. Before we got really good, thin-skinned, good-flavoured fruit the trees must have acquired age, and, therefore, the early death of the trees through the ravages of disease could not be regarded in any other light than as a national calamity. Mr. M'Donald being a man of experience in gardening, and holding a position of influence among gardeners, had done some good by disputing the longevity of the citrus tribes, and there was no doubt that still greater good would be gained by a discussion of the whole question, as suggested by Mr. P. Hogan. Most probably Mr. Robinette had hit at the foundation of the evil when he suggested that it was due to the stock upon which the sweet orange was grafted. If seeds were taken from fruit raised upon sickly trees, or those which were weakened by any cause, and the seedlings were afterwards grafted, it might be that the trees grown this way would be short-lived. But Mr. M'Donald did not seem to notice that there is a difference between natural decay and decay caused by disease, and, in opposition to the facts adduced, still made a pretence of clinging to his idea, ignoring the statements of some of our most eminent botanists and horticultural writers and pinning his faith to so much of one person's statement as suited him—that of Don Jose de Canto, whose remarks were made with reference to the orangeries of the district of all others most liable to the attacks of the disease. If that gentleman's very able letter—or so much of it as they had been favoured with—were carefully read without prejudice, it would be found to bear out, literally and generally, all that Mr. Pascoe contended for; and if they followed the course adopted at the Azores, instead of quietly watching the destruction that was going on, and bemoaning their fate, they would stand a chance of obtaining the same result. The facts of Don Jose de Canto's letter, which were admirably dealt with in a leading article in the *Sydney Morning Herald*, were as follows:—Until 1836 the orange trees budded, blossomed, and fruited with unvarying regularity. The grower would as soon have suspected the sun of variation from his diurnal course as the orangeries from their yearly round of duty. They were handed from father to son, and lasting as they did from generation to generation, it is not surprising that they became a symbol of permanence. These trees cost the growers no care, no attention, no labour, save the labour of picking and packing, so far as we can understand. The people ate and drank the year round, and the orange would blossom and fruit the year round without trenching, without manuring, without [illegible] without pruning. The plant was neither fickle nor fastidious, and the islanders rejoiced in their orange trees. Suddenly, however, there came a change. This bright picture of the growing, green-leaved, self-contained tree, surrounded by a joyful, sun-loving, dancing people, dissolves away, and gives place to a pale-leaved and sickly tree, surrounded by a care-faced and inquiring population. Their first proceedings were those of the panic-stricken, they were carried to extremes. From absolute indolence they rushed into alarming activity; but it was the blundering activity of ignorance. Having had little need to inquire into the physiology of the plant, or the relations subsisting between the soil and the plant, they adopted measures to set things right which outraged both, and only made things worse; but gradually, by the aid of the suggestions of science and a teachable disposition, a middle course was hit upon, and restorative processes were prescribed with an intelligent knowledge of the patient's requirements. At first the trees were overloaded with manure and stifled with shelter and a great deal more was done to them than they well could bear. Now they perceive that thorough drainage is at the foundation of successful orange growing; that, next to this, trenching to a great depth is essential; and, thirdly, that manure must be applied—but with discretion. It is true the trees are more fickle than they were, and die more frequently, and the fruit will not keep so long. But growers can again count with tolerable certainty upon their crop. The disease of the orange was first discovered in the Azores in 1836, when it was found that the oldest and best trees, as much as 200 and 300 years old, and producing each 6,000 to 20,000 oranges, were disappearing. It was observed that all the trees affected produced a very heavy crop the very year that the disease manifested itself, that the leaves became yellow and fell off in great quantities, and on the trunks or stems near, and sometimes beneath the ground, the bark opened, and drops of a kind of yellow gum exuded. The drops resemble tears (*ligrimas*, in Portuguese, and therefore the disease was named lagrima. Many orangeries were quite destroyed, and a remedy was eagerly sought. Opinions as to the cause of the disease were much divided. Many thought it must be that the orange-tree had a limited period of existence and this being reached, the tree must thus naturally decay. As we then only propagated trees by layers, this explanation was not thought to be unreasonable, but afterwards it was found that seedlings were attacked in the same way. Then it was found that superabundance of moisture in the soil was one of the worst conditions for the disease. Soon it was discovered that the destruction of the diseased bark and wood in the stem of the tree was the best method to save it. From February till August a skilled horticulturist visits every tree, and at the slightest sign of exudation of gum he cuts the bark across, to allow it to run out. If the disease is in an advanced state, the bark and the whole of the diseased wood is cut out, the roots being bared to a distance of a foot or two feet from the stem, every portion of diseased root being cut away. By this means the tree is cured if the disease is found at an early stage; of not, it is dug out and a fresh tree put in from a reserve which is always kept for such contingencies. Although the disease still continues the gardens now look very prosperous, for the remedy is known. . . . So we are returning to the old traditional culture. We are clearing the shelters, pruning the interior of the trees for the admission of air and light, are less liberal with manure, and keep the ground free of weeds, except when we want to excite vegetation. We have abandoned propagation by layers, and graft good chosen kinds upon seedling stocks For shelter we prefer trees with their foliage, and take care not to let them grow too high From these abstracts of the contents of the letter referred to, and the leader it would be seen that in the Azores for hundreds of years they had grown the orange successfully and without trouble, and previously to the outbreak of the disease (*lagrima*) they had trees 200 to 300 years old, producing immense crops of from 5,000 to 20,000 each. In 1836 the disease broke out, spreading consternation and ruin, but remedies were discovered in time, and in 1868, when Don Jose de Canto wrote, the disease, though still existent, ceased to cause uneasiness; and although the fruit was inferior to that formerly produced, confidence was restored, and growers were "returning once more to some of the old traditional culture." It certainly appeared a strange method of reasoning to endeavour to prove by the statement made in the above letter that the orange was a short-lived tree. The opinion ventured that those trees which have attained great age have got into places particularly favourable by Nature and circumstances was a most important one, and contained the very gist of Mr. Pascoe's argument. Nothing he could say would more fully sustain it. It was a well-known axiom, "Like causes produce like effects; and knowing as they did, not only single trees, but groups and plantations, of vast age and in great vigour, it was their duty and (with present prospects) necessity to inquire into the attendant circumstances with a view of remedying existing evils. The idea that the genus citrus had lived its allotted time, and had so degenerated, that its course might be said to be finished, seemed to him too ridiculous for consideration, and totally opposed to all theories of rise, progress, and decay that he had ever met with. It was a very convenient doctrine for Greeks and Mohamedans, and those who believed "whatever is, is right," or were too indolent to investigate causes. Disease in fruit trees and fruit-producing plants was of common occurrence, and the citrus family did not stand alone; but perhaps of all the fruit trees they were acquainted with they had enjoyed less opportunity of studying the nature and habits of the orange than that of any other. The culture of it in its natural habitat was unknown to them, and its natural age was so great that they could do little in a generation, but, having it in their midst, they must study its nature and treat its diseases as they studied the nature and diseases of other fruit trees. When the odium broke out in France the people did not stand idly bemoaning their loss, nor did they imagine the vines had lived their time, but they searched into the character of the disease and found a remedy by which we at the present day benefited. The "American blight" attacked the apple-trees, but the gardeners found out in time that the aphis could be beaten, so far as the roots were concerned, by grafting upon "blight-proof" stocks. The apricot, peach, plum, almond, and other trees were subject to fungoid growths and encroachments, but gardeners found a remedy in sulphur, &c. So with respect to the orange, a careful study of the subject, with careful observations of all the conditions, would be very interesting, though perhaps slow; but in time a fact would be discovered here, and something from there, until a mass of information would be gathered which would enable them to cultivate the orange as successfully as any other fruit tree. That our orangeries were seriously diseased was an admitted fact—from every district in which trees were planted came the same story. One by one they were losing their oldest and best orangeries, and many of those newly-planted were looking very queer, but so little attention had been paid to the subject that they could not even tell what the disease was, or give any definite idea of its cause Its effect they all new too well; but as far as he was aware no one had made any systematic attempt to cope with it. Several, for very shame's sake, had made pretence of doing something, but, having no definite object in view, had accomplished nothing. He thought their attention should be chiefly directed to the nature of the soil, the method of production, treatment during early stages of growth, and manner and time of watering. As regarded the first, Risso told them that at Genoa and Florence

they were grown in a strong yellow clay, richly manured; this was considered by Italian gardeners to be best suited to the orange tribe. He also said that in France clayey loam, rotted vegetable matter, and rotted horse-dung were considered the best compost. Our ideas as to a suitable soil were quite opposed to this, and we sought a sandy loam with a gravelly subsoil. In his (Mr. Pascoe's) opinion some most radical changes and improvements must be made in the method of production. It was his firm belief, after carefully watching the matter for years, that the stock they worked upon was the chief cause of the mischief—in fact he had seen the stocks of one year-old trees as they came round from Sydney so bad with disease that it seemed a sin to sell them for planting. The question then arose, how were they to propagate. Layers were generally condemned—how deservedly he was in doubt; the stocks in present use they knew to be bad; then what must they use? Experience only would tell them. Miller recommended citrons; London citrons and Seville oranges, and he had heard experienced horticulturists recommend the poor man's orange and the shaddock. His advice was to try them all, though he believed the Seville would be found the best stock the orange family could be worked on. Mr. Moore, of Sydney during his investigations into the nature of the disease in Europe found those trees worked on Seville stocks to be almost free from disease, and it is a noticeable fact that the great majority of those trees in Spain now flourishing and from 600 to 700 years old, are Seville, and were planted before the sweet orange was introduced into Europe. The treatment of the tree when young was of vast importance. That any tree should be pampered and forced, or allow to produce heavy crops when young, was totally opposed to all physiological laws, and Lindley said the abstraction of fruits and flowers augmented the vigour of the branches, or of the parts in connexion with them, and that the removal of any part which takes up a portion of the food employed in the support of the flowers increases their luxuriance. The manner and time of watering Mr. Pascoe would leave to men more practical than himself. They were told on good authority that the citrus family did not like cold or excessive moisture; but to see the way in which they were inundated sometimes one would almost imagine they were semi-aquatic plants.—*Australasian.*

COTTON STATISTICS.

We take the following from the annual report on "Cotton in the Bombay Presidency," issued by the Commissioner of Customs, Opium, and Abkari:—

The most important cotton-producing districts in British territory are Ahmedabad, Broach, and Surat in the Northern Division, Khandesh in the Central Division, and Belgaum, Dharwar, and Kaladgi in the Southern Division, each of which, except Belgaum and Dharwar, had larger areas under cotton cultivation in 1879-80 than in the previous year, and the out-turn correspondingly larger. In Belgaum, although the total area cultivated with cotton in 1879 80 was smaller than that of 1878-79 by 2,972 acres, and in Dharwar by 6,298 acres, it yielded a better crop than that of the previous year, which had suffered by the ravages of rats.

The districts of Kaira and Panch Mahals in the Northern Division, those of Nasik, Ahmednagar, Poona, Satara, and Sholapur comprised in the Central Division, and all the five districts in Sind, grow cotton to a small extent, while the districts of Thana, Kolaba, Ratnagiri, and Kanara do not grow it at all. The area brought under cotton cultivation in Sind in 1879-80 was less than three-fourths the area similarly cultivated in 1878-79, owing, it is said, to fear of the floods.

Among foreign territory, the province of Kattiawar has the largest area under cotton cultivation, the area so cultivated in 1879-80 being 1,053,800 acres as against 710,928 acres in 1878-79. The next in importance is Baroda in which cotton cultivation increased from 161,284 acres in 1878-79 to 280,341 acres in 1879-80. States in the Southern Maratha country had 194,080 acres of land grown with cotton in 1879-80 against 189,618 in 1878-80. The States of Cutch and Akalkot, and those comprised under the Mahi Kantha, Rewa Kantha, and Palanpur Agencies grow cotton to a small extent, and show for 1879-80 some fluctuation compared with the areas under cotton cultivation in 1878-79.

The season was most favourable to cotton cultivation throughout the presidency; but crops suffered to some extent in Khandesh from later excessive rain, and in Dharwar, Kaladgi, and Southern Maratha country from blight.

The total area brought under cotton cultivation in British districts in 1879-80 was 2,109,591 acres, being in excess of that similarly cultivated in the previous year by 300,169 acres; while the area in foreign territory increased from 1,171,450 acres in 1878-79 to 1,648,604 acres in 1879-80, or by 477,154 acres.

CULTIVATION OF THE FIG IN TURKEY.

The United States' Consul at Smyrna states that the Aidin district is the only one which produces figs for exportation. The fruit will grow anywhere in the neighbourhood of Smyrna, of a good quality for consumption, in a green state; but the Aidin plain is unique in its climate and soil as being favourable for the proper curing of the fig. The thermometer seldom falls below three or four degree under freezing point, and in the summer seldom rises above 130 degrees Fahrenheit in the sun. In Aidin, the winters are generally wet, the dry weather commencing in May and continuing till the end of October. Any rain at the end of July or during the month of August and September, when the fruit is under the process of drying, injures the quality by causing it to burst, hardens the skin, gives the fig a dark colour, and spoils its keeping quality. Heavy dews will cause the same evils.

The fig tree will grow in almost any soil; a rich heavy soil is, however, preferable; but to produce figs that will dry well and please the merchant, the soil ought to be of a good depth and of a rich, light sandy nature; this, if the weather be favourable, will produce large figs, of a white thin skin, and of the finest quality. Before planting the ground is well ploughed two or three times, to a good depth, well fertilised, and freed from all weeds and extraneous roots. The fig is propagated from slips, selected with as many fruity buds as possible. To form a tree, two slips are planted, one foot apart, and then joined at the top. The trees, if planted in rich soil, should be placed about 30 feet apart, and for poor soil, about 25 feet distant from each other. The cuttings are planted in the month of March, two in each hole, at about 9 inches or a foot apart at the root end, and during the growth of the trees, the ground is ploughed up two or three times during the winter or spring, and the space between them is used to cultivate cotton, sesame, or Indian corn.

The fig harvest generally lasts about six weeks, and when the fig is ripe, it falls of its own accord from the tree. Women and children are employed to pick up the fruit into small baskets, to be conveyed to a place in the garden well exposed to the sun, where they are spread on a bed of dry grass, or matting, singly, and not one on the top of the other, and are turned over every day, in order to get every part of the fig exposed to the sun. After a few days of this exposure, those figs which are sufficiently dry are selected from the mass, and divided into first, second, and third qualities, care being taken not to dry them too much. They are then sent to Smyrna, where they are assorted and packed for shipment.

On arrival at Smyrna, they are conveyed to the fig bazaar, or market place, where the merchants attend early next morning to effect purchases. The parcels belonging to each individual owner are separately examined each purchaser giving his own price; a broker is nearly always employed as an intermediary by the merchant on payment to him of 2 per cent. of the value, the amount being ultimately refunded by the seller. A seller is but seldom the owner himself, this latter being generally represented by a Jew or Armenian merchant, at an exorbitant charge of 7 per cent. as a commission. The figs are then, after purchase, conveyed to the packing establishment, to undergo manipulation and putting into boxes; the sacks are emptied out on the floor in a square heap and on all sides are squatted rows of women and girls, employed in merely twisting round each fig two or three times between the forefinger and thumb, to render it soft and give it the required oblong form. On the heap are a row of low baskets, into which are thrown separately the first and second qualities to be used for packing; at least 10 per cent. of the whole mass is worthless for putting up in cases, and, during the first process, the inferior fruit is picked up and thrown in a separate heap. Undersized, tough, or spotted figs, and such as are burst, come under this category, and are packed, or rather preserved, promiscuously in small boxes, and labelled "Figs for family use." Sometimes, when the parcel is unusually good, three qualities are selected instead of two. The figs are then laid on long benches at which are seated the practised packers. Each man has a box before him, and swiftly and dexterously the figs are placed alongside each other in rows, the rows varying in number according to the depth of the box, the flat ones, which are in more general use, requiring but two. This mode of packing is called "pulled." Above all, a row of "layers" is then placed, to show the figs to advantage. The "layers" are stretched out by means of both hands, and laid flat side by side in parallel rows. Of late years, "layers" throughout the boxes have come into great demand, and nearly all the best qualities are packed in this way. In packing, the fingers are now and then dipped into a bucket of sea water, to ease their working; the figs become thus moistened with salt water, which it is said has the effect of hastening their sugaring. The boxes are again passed on to the women, who complete the process by placing laurel leaves between the upper rows, before the final nailing down and polishing off by the carpenter. The packages used are of various dimensions and forms; at one time all figs exported to the United States were placed in drums or paper boxes, but of late years flat wooden boxes are being extensively shipped. Very few drums, if any, find their way to the English market, to which the best qualities are usually sent. America consumes but little of the superior qualities, though the demand for such has now increased. Small canvas bags are now being used with much success, and in fact, every season some novelty in the style of packing may be noticed. The refuse, or "naturals," are put into large boxes or barrels, and shipped to England, Egypt, Europe, and Turkey, the high rate of duty in America entirely excluding those inferior figs from the market.—*Journal of the Society of Arts.*

NOTES ON USEFUL PLANTS.

(from the Kew Report for 1879.)

The report on the Royal Gardens, Kew, for 1879, which has recently appeared, contains some notes on the introduction and acclimatisation of useful plants into India and the Colonies, which may be interesting to the readers of the *Journal.*

With regard to those important medicinal plants, the cinchonas, Sir Joseph Hooker deals firstly with what are known as Columbian barks, namely, those producing the *Calisaya* of Santa Fe, and the hard Carthagena barks. Both of these are of an extremely valuable kind, and only a few plants remained at Kew at the close of the last year. One of these was sent to Jamaica, from whence the Superintendent of the Botanic Garden reports:—"Our specimen of Carthagena bark is in splendid condition. We have now seventeen well established cuttings, with promise of more." The remainder of the plants were sent to India, and a subsequent report from Calcutta says that they are doing well, and there is every probability that they will soon be successfully propagated.

Regarding the extended cultivation of the well-known species of cinchona, *C. succirubra*, *C. officinalis*, and *C. micrantha*, reports are given from several centres. Thus, from Assam, Mr. Mann says with respect to the small patches of cinchona plantations below Nungklow, in the Khasia Hills:—

"*Cinchona officinalis* appears to be healthy, the other two species (*Cinchona succirubra* and *Cinchona micrantha*) all present a sickly appearance, and most of them have only a few leaves at the extremities of the branches. Both species flower sparingly and form no good seed-pods. This condition of the plants is ascribed not so much to the climate and altitude as to the very steep slope and shallow surface soil resting on rock, which does not retain sufficient moisture to suit these plants. The plants of *Cinchona succirubra* near Jirang, look very much better, and both altitude and situation, as well as the soil in that place, seem to be more suited to this species than in the Nungklow plantations."

From Burmah the report of Major Seaton is not very favourable on the prospects of cinchona cultivation. The plantation seem to have been made so far back as 1879. He says:—

"All things considered, the cinchona experiment does not promise well. The oldest trees dying off, and the trees of very small size flowering and fruiting freely, are only too sure signs that the tree finds itself in a site not adapted to its requirements." It appears, however, that a Ceylon planter has made inquiries about a grant of land in the neighbourhood. It is possible that with the technical knowledge as to the methods of cultivation of cinchona, and of obtaining a speedy financial return from it, which have been worked out in Ceylon, a better face may be put upon the experiment in Burmah."

At Gadcrif, near the frontier of Abyssinia, *Cinchona succirubra* is said to do well. In Ceylon, it is stated that—

"The enterprise of the planters, and the necessity of obtaining a speedy return for invested capital, has led to much more rapid methods of harvesting the bark crop being adopted in this Island than at the first commencement of the enterprise would have been thought possible. The following statement appeared in the *Ceylon Observer* for Septem-

ber 18th, 1878:—"Over large areas in Ceylon it seems as if *Cinchona officinalis* came to maturity in four and-a-half years, while if trees begin to show signs of canker or decay at even two and-a half years, the bark ought at once to be utilised. Bark of such trees will pay well for the gathering. We once sent to Messrs. Howard a specimen of bark from three and-a-half years old trees. The verdict was, 'good marketable bark as it stands.'"

From Jamaica, the Superintendent of the Botanic Gardens writes:—

"My chief care at the cinchona plantation is the establishment of large open air nurseries instead of the glass propagating houses which I found here. I sow the seed under thatched sheds, and prick out the plants into beds shaded by ferns. This is a simple inexpensive style, which is universally adopted in Ceylon but unknown here. I fear that the system of glass houses and propagating and hardening frames has done much to frighten people from trying cinchona here and besides [the Government plantations] have never been able to distribute more than a few hundred plants, as they had not enough for their own use. In a few months, by next planting season, I shall have 80,000 which I can conveniently spare and by the end of the year, possibly 50,000." * * * * "Unless the trees are planted thickly enough to 'bower' the ground, as the planters say, the cost of weeding is nearly £4 per acre per annum. But the third year the trees, if well planted and well supplied, ought to cover the ground and save all subsequent weeding."

In the Mauritius:—

"The cinchonas have grown but slowly. Few experiments have been made with the plants, owing to more pressing work. The plants planted in the forests at a greater altitude than that of the gardens have not grown satisfactorily, but it is hoped some method of growing this useful plant, which will give beneficial results, may still be hit upon; only it must differ considerably from that of other countries."

From Singapore:—

Mr. Murton (Superintendent of the Botanic Gardens) reports:—

"All attempts to grow this here have proved fruitless, but *Cinchona calisaya* and *Cinchona succirubra* are likely to do well at 2,000 feet elevation in Perak."

While from Tinnevelly:—

Col. Beddome reports:—"A few plants were sent from the Nilgris for trial in this district (1856), and the *Cinchona succirubra* plants were put down at an elevation of about 3,000 feet, in a small clearing in the ghât forests; they have been left entirely to Nature, but owing to the moister climate the growth contrasts very favourably with that of Neddivattum or elsewhere on the Nilgris. During my last inspection I found one of the larger trees to be nearly 50 feet high; it had three large stems at about one foot from the base, the leaves having, it was said, been broken by a monkey when young."

Regarding the cultivation of cinchonas in Sikkim, the report of Dr. King published in the *Journal* for September 3rd last, p. 809, is of a subsequent date to that quoted in the Kew report.

On the subject of *Eucalyptus* planting, Sir Joseph Hooker reports as follows:—

Seeds of species of this Australian genus are continually asked for, and supplied from Kew. The following notices represent the progress made in the cultivation in various parts of the world:—

ASSAM.—Mr. Gustav Mann reports:—"*Eucalyptus globulus* is by far the fastest growing species cultivated in the Khasia Hills, next to it comes *Eucalyptus rostrata*."

BENGAL.—Dr. King remarks:—"The *Eucalypti* from Queensland give little more hope of success than the more southern species, by the planting of which in the plains of Bengal sanguine people hoped to abolish malaria."

BOMBAY (NORTHERN DIVISION).—Mr. Shuttleworth reports:—"Seeds of different varieties of *Eucalyptus* were sown; nearly all failed. A few of *E. rostrata* are surviving."

BOMBAY (SOUTHERN DIVISION).—Col. Peyton reports that the plantations of different species of *Eucalyptus* do not appear to prosper, and "their numbers are rapidly diminishing," . . "They are weedy and whip-like in growth, and require to be propped up to prevent falling over." Near Dharwar what is supposed to be *E. resinifera* appears to prosper. "Four trees are remarkably fine, although only six years old. They have attained on an average 40 feet high, and are five inches in diameter five feet from the ground."

JAMAICA.—Mr. Morris reports:—"Of Australian trees the most desirable here is *Grevillea robusta*, which is adapted for nearly all elevations, and stands wind well. The gums (*Eucalyptus*) get very much blown and seldom look well except in clumps, where, for the first four or five years they are sheltered on the outside by other trees."

SAHARUNPORE.—Mr. Duthie reports:—"There are at present upwards of 31 species under cultivation in these gardens."

"The healty appearance of some of the kinds, and the rapid growth they are making are sufficient reasons for encouraging their extensive cultivation in India." This is in accordance with what is known of the climate of that (extra-tropical) part of India.

SINGAPORE.—Mr. Murton reports:—"When sown *in situ* they seem to thrive fairly well in Singapore, but do not appear to stand transplanting. *Eucalyptus siderophloia*, *E. Baileyi*, and one or two other species are growing well in the nursery."

ZANZIBAR.—Dr. Kirk informs me:—"The *Eucalyptus citriodora* from Queensland is now in less than two years from seed about 18 feet high, with wide branches."

On the very important subject of fodder plants, the Kew authorities have a great deal of information, as the following extracts will show:—

GUINEA GRASS (*Panicum jumentorum*).—This, it appears takes the place of all other fodder grasses in Dominica, as it is hardy and requires but little cultivation.

Dr. Imray says:—

"By keeping the lands down and a little manure occasionally, it may be cut down, crop after crop, for many years. I have had a guinea grass piece treated in this way for full twenty years.

PRICKLY COMFREY (*Symphytum peregrinum*).—From various trials that have been made, it has been shown that this plant, although of great utility as an early fodder crop in cool and temperate countries, is not adapted for cultivation in hot countries:—

MADRAS.—The Agri-Horticultural Society report:—"Experiments with Prickly Comfrey have failed, the plants which were in the gardens, though receiving rather more than their fair share of attention, having one by one perished."

SAHARUNPORE.—Mr. Duthie reports:—"I do not believe that the conditions at Saharunpore, as regards either climate or soil, are favourable for the profitable cultivation of this plant. At Chajuri it thrives fairly well. Three crops were taken during the year from 35 roots growing 3 feet apart. The average weight of each crop was 30 lbs."

SOUTH AUSTRALIA.—Dr. Schomburgk reports from Adelaide:—"Prickly Comfrey has again been a thorough failure, and it is now a fact that this plant is of little use, at least, on the south Australian plains."

On the Teosinte (*Euchlæna luxurians*), Mr. Woodrow reports as follows from Bombay:—

"*Euchlæna luxurians* produced a heavy crop of forage when treated as a garden plant, but not better than would be given by sugar-cane in the same circumstances. When treated as a fixed crop, under the same condition as Jowaree, the produce was inferior to that crop."

QUEENSLAND.—Mr. Walter Hill reports from Brisbane:—"The seeds received by me were duly planted, and grew both strong and healthy, flowering about the month of May. From the opportunity I have had of judging of its nutritive qualities, I am not of opinion that it can be grown to much advantage in this colony; the stalks appear to be too fibrous and hard to possess much nourishment. I shall, however, make further experiments."

SAHARUNPORE.—Mr. Duthie reports:—"As far as cultivation is concerned, success has been complete. The majority were fine, healthy plants, and an abundant supply of excellent seed was produced."

SINGAPORE.—Mr. Murton reports:—"This grass, although useful, does not bear out its reputation in the Straits. Large quantities of seeds have been distributed, but all accounts from the Native States state that it pays far better to grow maize, as the same ground that will grow Teosinte will produce excellent maize."

SOUTH AUSTRALIA.—Dr. Schomburgk reports from Adelaide that, notwithstanding the disastrous drought of the early part of 1879, "the prevailing dryness did not injure the plants, showing not the slightest effect on their leaves, which preserved their healthy green, while the blades of the other grasses suffered materially. . . . At the Government garden, at Palmerston, in the Northern Territory, the growth of the *Euchlæna* has been surprising. In the course of five or six months the plants reached the height of 12 to 14 feet, and the stems on one plant numbered 56. The plants, after mowing down, grew again several feet in a few days. The cattle delight in it in a fresh state also when dry. Undoubtedly, there is not a more prolific forage plant known . . . . I can recommend it as a most valuable summer forage plant in our dry climate, especially if it can be planted in a moist soil. The only drawback with us will be that the ripening of the seed crop will be problematical, as early frosts will kill the plant."

The most recently introduced fodder plant is known as the Tagasaste (*Cytisus proliferus var*).

"It is a shrub indigenous to the Canaries, the leafy branches of which are said to be a useful fodder. It requires a light dry soil, and is rather intolerant of frost in winter. The plants should be placed 6 to 10 feet apart, may be cut two or three times a year and will last 10 to 20 years. Thirty-five pounds of fresh-chopped Tagasaste mixed with 20 lbs. of chopped straw is said to be sufficient for the daily nourishment of a horse or cow. The seed is very slow in germinating. The seed was pretty widely distributed from Kew. It is too soon to expect the results of trials at present"

MADRAS.—Most of the seedlings died off after germinating, Colonel Grant reports at commencement of present year:—"At present only two or three are looking healthy, and from them I should think very little fodder could ever be obtained."

SOUTH AUSTRALIA.—Dr. Schomburgk reports from Adelaide:—"The seeds were sown, and all came up. The growth of the plant is vigorous, some of the plants having reached 2 to 3 feet, looking healthy, not in the slightest degree affected by the severe dry weather we have had to contend with. I have many plants for distribution."

(To be Continued.)

MINERALOGY.

THE imports of petroleum into Java have increased from 367,746 cases in 1876 to 1,719,801 in 1880. The monthly consumption of petroleum there, amounting to 22,500 cases in 1875, rose to 104,150 in 1880.

WE see it is proposed at home to establish a Gold Institute, with its three principal departments of chemical, mechanical, and practical, on the lines of the existing Iron and Steel Institute, which has done so much for the particular industries and productions with which it is conversant. The new institute whilst recognising the maternity of the Society of Arts, which has been the fruitful mother of scientific and technically industrial offspring, will from the beginning have its own separate organisation; and it will start with a very valuable nucleus of a library and museum, towards the formation, of which Mr. Lock has offered his rare books on metallurgy and his illustrative collections of spicimens, as a first contribution.

AUSTRALIA is increasing her yield of gold, according to the *Melbourne Argus*:—

The estimated total product of gold for the year ended 31st December last is 812,092 oz., the best return on record since 1876, and nearly 100,000 oz., better than in 1879. The improvement thus manifested began towards the close of 1879, and the state of affairs throughout the colony leads to the belief that it will be maintained throughout 1881. To arrive at the estimated yield, the following amounts are added together:—Total exports, 193,058 oz., total amount received by mint, 587,015 oz; net balance held by banks on 31st December, 32,019 oz.; total, 812,092 oz. Work which was interrupted by the holiday, has since been resumed, and the stock market remains active.

FROM Queensland we read "The Charters Towers escort brought down 85,000 oz. of gold last year."

THE following facts, if they can be relied upon, go to show that petroleum ought to be sold at a much cheaper rate in the world than it is. An American paper, hailing from the oil-producing region of Bradford, states that there has run to waste in that

district since midsummer 1880 something like 600,000 barrels of oil. There are, it goes on to say, in the district, in round numbers, 8,000 producing oil wells, with a daily yield of 70,000 barrels. The daily demand, on the other hand, comes to 55,000 barrels. The accumulations of oil long ago, it says, exhausted the storage capacity that had been prepared, and that, in consequence, for three months of the past year, 6,000 barrels of oil have been running to waste every day. The estimate is that in wooden tanks at the wells there are 2 million barrels of oil stored, and in other storage tanks 8 millions, making a total of 10 millions of reserve stock; while, in addition, improvised tanks are being constantly constructed.

THE production of gold in Russia is said to be increasing steadily, and how welcome such a fact will prove to the nation, if the discovery of the new veins of the precious metal, and the improved machinery set to working them, continues to increase the outturn. From the statistical returns of the Russian mines, that outturn has still to augment very largely to keep pace with the requirements of the nation, as it grows in wealth and enterprise. From the year 1866, the total outturn of the gold mines of Russia, for each quinquennial period up to 1880, has been as follows:—

Years.		Total.		Yearly average.
1866 to 1870	...	£4,200,000	...	£840,000
1871 to 1875	...	£4,700,000	...	£940,000
1876 to 1880	...	£5,000,000	...	£1,000,000

IT is within the range of possibility that coal may be found in workable quantities not far from the town of Singapore. A sample of that mineral has been found in the excavations at Teluk Ayer, and Mr. William Adam, the manager of the works, who has had large experience in mining both in Scotland and in Borneo, considers that there are sure indications of coal fields in the cuttings, and that a workable seam might possibly be discovered were the ground bored and properly prospected. It is premature to speculate on the importance of coal fields to a port like Singapore, but it is to be hoped the matter will not be allowed to rest without further inquiry.

THE OIL WELLS OF ARAKAN.

FROM time to time scanty accounts have appeared in our columns on the working of these wells; and these meagre statements have arisen, chiefly, from the reluctance of those interested in the undertaking, to furnish the necessary information on the subject. We are, however, in a position to give our readers some particulars as to the advance made in this direction. The two main districts, in which work has been going on, are in the Borongа Islands and Kyouk-Phyoo; in which two separate concessions have been granted. The oil resources of these districts were first brought to public attention at the Akyab Exhibition of 1875, and for some time afterwards, a grant was given to Mr. Savage of an area of one square mile for inspecting purposes. Mr. Savage, it seems, "struck oil" in one of his wells in 1878, and although the flow was considerable for a time, it eventually fell off. Mr. Savage is now raising very little oil in this district, his energies and attention being principally devoted to those of his fields, where we believe the quality is much superior than that obtainable at the Borongas. On the Eastern Borongа Messrs. Gillam & Co. have obtained a concession for oil and coal getting. The concession granted to them extends over an area of four square miles, and the Company has a subscribed capital of £10,000, and have sunk four wells namely, the *Gads* yielding, as the report under review states at first 35 barrels a day, and subsequently when visited by the Chief Commissioner, only four or five barrels, by hand pumping. This well has been sunk to a depth of 976 feet. No. II is called the *Sladen*, and is at a depth of 800 feet, producing about three barrels a day by manual labour. The next is the *Arnot*, 850 feet deep, but the well, at present, is unused, the Company waiting for machinery to work it properly. The last of the wells is the *Gillam*, sunk at a depth of 400 feet; and on this well, the only engine at work on the Island, is erected. We believe it is the intention to carry this well down to some 1,800 or 2,500 feet as a test well, until the oil bearing strata shall have been fairly proved. Amongst the other points of interest connected with the working of the Borongа Oil Wells, it is worthy of note, that the workmen on the island have mutually agreed between themselves to carry out temperance principles. The climate of the oil settlement, though perhaps not of the best, yet we are glad to observe that both Europeans and natives have been fairly free from fever, notwithstanding the rough buildings, that have been erected, and in which the people have lived in during the year round. We are, however, given to understand that it is contemplated to have better dwellings constructed for the Canadians and other European workmen on the island. The oil produced in this district is clear like pale sherry, and is reported to be about 80 per cent. purer and better than the crude oils obtainable either from Pennsylvania, or Ontario, and finds a ready sale at Rangoon, Calcutta, Chittagong, as well as in the local markets, at prices varying from Rs. 10 to Rs. 15 per barrel. The oil is stated to flash at a temperature of 148. Fahrenheit by the open test.—*Arakan News.*

THE COST OF PRODUCING GOLD FROM QUARTZ.

MANY sacrifices must be made in order to obtain the precious product, sufficient to yield in due time twenty to thirty per cent. dividends. A report lately drawn up on this subject by Mr A. W. Forde, the Consulting Engineer to the Bombay Municipality, gives some valuable information with regard to cost of production. He does not ask us to trace the difficult course of the stamping and other machinery from its cradle in the English foundries to its working in the plateau. He cuts short that interesting history by intimating that he has gone all through it and ascertained that 'the expense of treating the quartz and extracting the gold . . . and all contingencies, I estimate at about Rs. 5-8 per ton.' In comparing this estimate with that given by Mr. Brough Symth in the official report which he submitted to the Madras Government in October 1879, we observe that the latter's estimate of the cost per ton amounts to 9s. 6d. This is based on actual cost in Australia. Mr Forde, in the report to which we have referred, advices that machinery for working gold mines should be especially prepared by first class firms at home who have been accustomed to make mining plant both for Australia and South America; and for the better guidance of these machinists, Mr Forde would have bulk specimens of the quartz sent, so as to enable the makers to adapt the crushing machinery to the special nature of the ore. Some of the gold companies, in the Wynaad more especially, are endeavouring to utilize water power as a motor. As steam often proves an expensive and difficult power to be worked in remote Indian districts, while fuel is always a costly item, as a general rule every effort should be made to use water where it can be obtained. It has already been stated that the cost of working one of the mines is something under Rs. 6 per ton. As gold may be reckoned at Rs 2 per dwt. (20 to the ounce), so three pennyweights would clear the cost, while one ounce to the ton—and this is a moderate estimate—being Rs. 40, will yield a profit of Rs. 34 per ton. But this presupposes that a fairly, large quantity of quartz shall be crushed per diem. The quantity of work done depends on the number and weight of 'stampers' used. There is a passage in Mr. Brough Symth's report which explains these 'stampers.' When worked out the operation stands thus:—10 stamps, costing £5,000 inclusive of cost of erection and building, will crush 25 tons in the 24 hours: 40 stamps, costing £20,000, will crush 100 tons. Then 100 tons at a gold profit of Rs. 34 per ton—Rs. 3,400 per day and in 300 working days Rs. 10,20,000 per annum. But as the sober business man will regard the profit as 'a dream of avarice,' we must let down the estimate to half an ounce of gold per ton of quartz, thus showing a profit of four lakhs twenty thousands rupees per annum or 85 per cent. on the capital. As to the question of probable yield there are plenty of data on which to form an opinion. One company have extracted 40 ounces from 44 tons of ore, and that too, with very indifferent machinery; and another company, with wretched appliances obtained 2-4-10 dwts. per ton. In Victoria where since 1860 the most complete statistics have been compiled, the average yield in the sixteen years ending with 1876 was 11 dwts 6·30 grs. Some of the companies in Australia have obtained from one to two ounces of gold per ton. There are grounds for believing that the quartz in some portions of the Mysore and Wynaad districts is richer than that of Australia. If science is worth anything, the promise of profit in this line of investment is safe enough; but there must be constant care and circumspection in the first plans and in the subsequent management of the concern, also a determination not to be discouraged by the preliminary difficulties that may have to be overcome.—*Bombay Gazette.*

GOLDEN SAND IN CANADA.

AN ounce of gold to the ton is a trifle as compared with the expected yield from some auriferous sand on the Riviere du Loup in Beauce, Quebec, Canada. Some of this sand has been assayed at the Metallurgical Laboratory Royal School of Mines, Kensington, and has yielded 14 ozs. 1 dwt. 3 grs. of gold and 1 oz 8 dwt. 19 grains of silver. The owners of 1,745 acres held in fee simple, and of mining rights over about 927 acres in addition thereto, ask but £15,000 in cash, and £80,000 in fully paid-up shares for the property:—

"The formation is of conglomerate and talcose slate and sandstone, with numerous small veins of quartz from which samples have been taken, showing free gold visible in the rocks. An analysis of a sample of this rock gives a result equal to 800 dollars to the ton. There are enormous deposits of auriferous gravel high up on the banks of the river, and it is proposed to commence operations by washing the gravel by the hydraulic method now so successfully employed in California and New Zealand under similar conditions. Two seasons have been devoted to the exploration and opening up of these deposits, and Mr A. A. Humphrey, who has conducted this work, estimates that there are 30,000,000 cubic yards of gravel in sight carrying gold at the rate of 30 cents per cubic yard, equal to 9,000,000 dols. The cost of washing this gravel will be 2½ cents. per yard—equal to 750,000 dols.—leaving a net profit of 8,250,000 dols., or £1,650,000 from this part of the property alone."

It appears from an official report to the Geological Survey of Canada that during the five days the writer was engaged superintending the experimental washing gold to the value of £31 8s. was obtained with pick and shovel at a cost of £15, leaving a profit of £16 8s.

GOLD RETURNS FOR VICTORIA IN 1880.

ACCORDING to our usual custom, we have obtained statistics which enable us to estimate approximately the yield of gold for 1880. The estimate is arrived at by taking the amount of Victorian gold exported in 1880, and the amount of Victorian gold received at the Mint in the same year, and adding thereto the difference between the amounts held by the banks on the 31st December 1879, and the corresponding date of 1880. It will be seen from a table appended to these returns that the large decrease on the return of 1877. A similar small decrease which had gone on annually for many years in the gold returns of the colony was checked in 1878, though there was then still a small decrease occurred in 1879 as compared with 1878; but towards the close of 1879 a decided improvement took place in gold-mining, which continued throughout 1880, and we have now for the first time since 1872, when the [illegible] gold-field was very prosperous, to record an increase. [illegible] increase is not by any means so large as some sanguine [illegible] it is still a most substantial one, and as the prospects [illegible] colony generally, and more especially on the great Ballarat [illegible] now very good, it may fairly be expected that the welcome [illegible] of 1880 will be continued throughout the current year. [illegible] the yield of 1880 [illegible]

as compared with 1878, was 85,585oz. ; but 1880 now shows an increase of 93,884oz. over 1879.

We have not been able to ascertain from the Mining Department, on account of the official returns not being yet complete, what was the mean estimated number of miners employed during 1880, or the estimated number on the 31st December last; but judging from the estimates published by the department for the other quarters of the year, the mean number may be taken to be slightly higher in 1880 than in 1879.

The Customs returns of the amount of gold exported during the years 1880 and 1879 give the following information :—

	Amount. oz.	dwt.	Value. £
1880			
Victorian gold	193,058	7	772,212
New Zealand gold	48,929	2	195,712
	241,987	9	967 924
1879.			
Victorian gold	214,197	16	857,294
New Zealand gold	91,758	2	367,244
	305,775	18	1,224,538

The returns from the Melbourne Mint, showing the amounts of gold received there during the years 1880 and 1879, were as follows :—

	Oz.
1880.	
Victorian gold	587,015·44
Foreign gold	171,705·40
	758,720·84
1879.	
Victorian gold	493,062·22
Foreign gold	163,493·62
	656,555·84

The quantity of gold held by the various banks on the 31st December last was 92,547oz., as against 62,582oz. 14wt. held by them on the corresponding date of 1879. By adding the amounts stated together, *viz.*, Victorian gold exported (193,058oz. 7dwt), Victorian gold received at the Mint (587,015·44), and the balance held by the banks on the 31st December last (92,547), a total of 812,092oz. is obtained, from which has to be deducted 62,528oz. 14 dwt. held by the banks at the termination of 1879—and therefore included in the Mint or export returns of 1888—leaving 812,092oz. as the total yield of 1880, as against 718,208 in 1879, or an increase for 1880 over 1879 of 93,884oz.

The following table gives the average number of miners employed during the past 14 years, and the amounts of gold obtained in the past 15 years :—

Year.	Number of Miners.	Yield of Gold. Oz.
1866	73,749	1,536,541
1867	65,857	1,493,831
1868	63,181	1,474,187
1869	68,087	1,367,903
1870	60,367	1,281,341
1871	58,101	1,303,879
1872	54,651	1,317,102
1873	52,544	1,240,407
1874	46,500	1,1 2,614
1875	42,000	1,058,823
1876	41,564	93 ,260
1877	38,882	792,839
1878	37,400	758,793
1879	37,553	718,208
1880	......	812,092

—*Australasian.*

FORESTRY.

THE administration report for the official year 1879-80 of the Forest Department in the Bombay Presidency, has just appeared. During the year the Forest Act of 1878 was brought into force chiefly by the influence of the late Governor, and a large area was added to the forest reserves. There are now close on 15,000 square miles of territory, divided into reserved and protected forests. Over the reserved portion the Forest Department has complete control, but certain rights are allowed over the area called protected. An officer in each forest district called a settlement officer was also appointed to settle all claims and questions of right. Fire still seems to give great trouble, and no means have at present been found to combat this great enemy of forest growth. It is, however, satisfactory to notice that the apathy which in former days characterised any attempts at preventing the yearly hot-weather fires of the forest region has disappeared. During the year the revenue has made a great bound towards a return to the prosperous days before the famine ; and although more superior officers have been employed, the expenses have been less than the estimates for the increased supervision. Several useful maps are issued with the report. Altogether considerable progress seems to have been made during the year in forest conservancy throughout the presidency.

During the year 1879-80 the Forest Department sold 1,512,220 maunds of fuel from the Darjeeling Reserved Division at an average price of Rs. 28-9-7 per 100 maunds ; while the expenditure averaged Rs. 24-11-9 per 100 maunds ; leaving a surplus of Rs. [illegible]. This surplus is less than in the previous year, and the [illegible] is attributed by the Conservator to the establishment [illegible] heavy in proportion to the amount sold. [illegible] sales was due to the competition of the Municipality competition which has now ceased. The Forest Department is to be congratulated from a departmental point of view on having at last secured the entire monopoly of the supply of fuel to Darjeeling ; the public are to be condoled with.

THE number of tons of sandalwood sold in Mysore in 1879-80 was 1,396½, about 310 tons in excess of the sale of the previous year, and the average price per ton was Rs. 354 against Rs. 338 of the previous year. The receipts from timber, &c., in the Reserved forests were only Rs. 40,813 ; that from district forests, chiefly from minor forest products amounted to Rs. 57,000.

ACCORDING to recently published statistics, the number of fruit-trees in Bohemia of all sorts, but chiefly apples, appears to be 14,000,000. Of these 10,000,000 are in gardens 1,600,000 in waste lands, and about 2,000,000 on the sides of the public roads. The number of young trees annually planted is about 1,500,000. Between 6,000 and 7,000 miles of road are planted with fruit-trees, mostly of the best sorts, and the revenue therefrom, is very large. The fruit is largely exported to the north of Germany and Russia.

FOREST CONSERVANCY IN INDIA.

ON Friday evening, January 21st, Sir Richard Temple, Barts., G.C.S.I delivered an interesting lecture before the Society of Arts, in London on the above subject. He entered first of all into a description of the principal trees which flourish in India, both in the plain and hilly districts. He referred to the deodar, or cedar as being one of the most useful of trees. Of the teak, he remarked that it possessed every virtue of which wood is capable ; it was good everywhere and under all circumstances, being seldom attacked by insects, its appearance always strikes the eye, as it rises straight up from the ground. Then there was the Sâl, commonly called "ironwood" on account of its great strength and durability ; it has a tall straight trunk with fine head. Of the *terminalia* there were two useful kinds ; one had a white and the other a black stem ; one resembled a pillar of white marble and the other a black column. Among trees of the plain, he mentioned the acacia (*babul*) which was used for every purpose of daily life ; also the mango which, besides furnishing a suitable article of food for the masses of the people, was fairly valuable for timber. He referred to the great forests of the Sunderbunds extending for thousands of square miles. There were India-rubber trees, bamboos, and several varieties of the palm, the date, the palmyra, and the cocoanut which latter tree supplied almost every want and was so valuable that even one or two constituted quite a little property.

Sir Richard spoke in glowing terms of the many other useful trees in India, and then came to the question how all this fine natural wealth should be preserved. But he remarked, the trees are valuable on two accounts, one being *economical* and the other *climatic*. As regards the former there are not less than thirty-seven millions of inhabited houses in British India, and the majority are made of wood. It might be imagined, then what an enormous demand there was for timber for house-building alone. Most of the domestic implements of the people are made of wood. There were not less than half a million villages in that dominion, and assuming that in each one there were from fifteen to twenty ploughs, it might be imagined how enormous was the demand for wood for agricultural implements. Then, as regards carts, they must be counted by millions ; and as for fuel, there was in most parts of India an absolute want of wood, and consequently the people used cow-dung, which ought to be reserved for manure.

As regards the climatic influence of forests, there are many people who consider that the drought of India are caused by the destruction of the forests. Too much must not be made of that. There is a certain amount of evaporation from the Indian Ocean. He did not suppose the total rainfall of the continent of India can be affected by forests, but the *distribution* of it is very much affected. The clouds pass over the dry plains and go straight on to the mountains. They arise in the Indian Ocean, and the first obstruction they meet with is along the western coast. They sweep over the dry plains of India, and meeting with the mountain ranges, their vapour is there condensed and causes torrents and rushing streams which swell the rivers making floods in the valleys, which could be prevented if forest were on the plains : a cold surface is presented to the clouds, and causes them to condense. If there are no forests, the clouds pass on until stopped by the hills. The same principle applies to the vapours which sweep over the plains of Bengal and are stopped by the great mountain ranges In regard to how forests affect the distribution of rainfall if there are no forests, the chances are that at one time there will be drought and another time immoderate rains, a period of flood almost always following upon a period of drought. It is to the forest that we must look for being blessed with the early and latter rains in due season.

The next point in reference to climate, is the retention of moisture. If the vegetation is destroyed, the streams run dry unquestionably. If the vegetation is preserved, the moisture is preserved for the dry season. This is important in those parts of India where canals exist, and if we are to retain our canal system, the forests must be preserved.

One more point in reference to the climatic consideration, and that is the preservation of pasturage. The cattle in India have too much food at some seasons and too little at others, the consequence is that they suffer from hunger during the dry months and are apt to surfeit themselves at the commencement of the annual rains. The great object is by preserving the forests to preserve the grass during the dry seasons. If there is a certain amount of forest land, grass will be sheltered from the sun and thrive so as to be fit for the cattle.

More ought to be done on the plains of India for the establishment of forests. Every village should be induced to establish a forest, which would afford a certain amount of timber and fuel, and also tend to preserve grass for the cattle.

These are the main reasons in brief why the preservation of forests is a matter of such vital concern in India. He now came to the measures to be taken for preserving these forests, and sorrowfully admitted the neglect of this subject which has prevailed in former years. Nobody was more zealous than he in vindicating the conduct of the Indian Government, and its officers, but he must admit that in the preservation of forests, we have not until within the last twenty years done as much as we ought to have done. Want of knowledge and technical education has contributed to the partial destruction of this great source of national wealth, so essential to the well-being of the country. We have now a large staff of trained

forest officers; he wished he could ail that they had been trained in this country. He referred to the project which had been started for establishing a school in Epping Forest, and said that hitherto our Indian forest officers have been trained in France and Germany, and it must be allowed that the school at Nancy has turned out excellent foresters. He could not see why it should not be done in England. A large forest was not necessary for teaching the profession of forestry, there are plenty of available woods in England, Scotland and Wales.

We have now in India a Forest Department which was second to none in the world. What does this department do? The remaining forests are divided into two great categories by law. Firstly, reserved forests, which are absolutely preserved; and secondly, protected forests which are imperfectly guarded and preserved. To give an idea of the extent of these forests he would mention the area in square miles. Bengal Presidency, 51,000 square miles; Bombay, 18,000; Madras 5,000; making up a great total of 69,000, say 70,000, square miles. This will be augmented by the many square miles yet to be marked off. He ventured to say that within a few years we shall have not less than 100,000 square miles of forest in India. The greatest portion is imperfectly protected, but still he thought nearly half was well preserved; at least 25,000 square miles are thoroughly guarded and preserved, and the whole of the great area named is under some protection. What does this preservation and guarding consist of, and to what purpose is it protected? It is first directed to the matter of wood-cutting. The forests are not treated by the Government in a dog-and-manger fashion. The timber is wanted for the use of man. Trees are not preserved for ornament, but use. As soon as a tree is grown to its full height and maturity it ought to be cut. In many cases the trees grow so thickly that thinning them is a positive benefit. The restrictions upon wood-cutting are not absolute, but instituted in order to ensure a number of trees being left for reproduction.

The next point is to regulate the practice of "*rab*," which means that the young shoots of the trees are burned and their ashes, which contain the necessary chemical constituents, are used for manure especially where the natural manure, *viz.*, cow-dung has been used for fuel. This cutting shoots and burning for ash manure, is a practice, which if not regulated will cause great damage to the forest. It is necessary to a certain extent.

Another matter is the prevention of the jungle fires, which are partly accidental and partly intentional, and when they are accidental present some of the most magnificent spectacles that can be imagined. Many people have been all night in the midst of these fires, which rush over the country, travelling at the rate of several miles an hour, the animals flying before the flames, in terror the inhabitants of the forest being caught in the flames and Europeans galloping to escape from the conflagration. The racking of the trees sounds like artillery; the trunks form pillars of fire and smoulder for a long time.

Fires are also intentional and lighted up every year to ensure a plentiful crop of fresh green grass for the cattle. That to some extent, is permissible in the months of April or May. Many of the hill tribes carry on their agriculture not by ploughing, but by means of burning the forest and letting the ashes lie upon the ground until the rain comes. This is a barbarous practice and arises from the ignorance of the people and their want of agricultural appliances. In extenuation it may be said that certain localities are very steep, and not easy to plough. The object of the British Government is to wean these people from the practice, by making small advances of money to them whereby they may purchase cattle and ploughs, so as to depend upon agriculture rather than burning the forests.

Forest conservancy is directed towards the preservation of the grazing. If cattle winter in the jungle, they will destroy ten times as much as they eat. The object is to restrict the grazing by means of the block system to allow the cattle to graze in certain blocks or areas of the forest, and to prevent them in others, so as to preserve the vegetation.

It will readily be perceived that when a question arises tending to restrict the rights of the people, there is always a contest between the forest officers and the civil officers. People who live in the forests have been accustomed to burn and destroy trees, and they can only be reclaimed by degrees; while on the one hand their rights are protected, on the other hand they must not be allowed to destroy the forests. In a judicious manner forests must be preserved, while a fair consideration is given to the old-established customs of the country.

Among the most distinguished Indian foresters he mentioned, is Dr. Brandis, a German Inspector-General, at once scientific and practical, and the author of an excellent work entitled "The Forest Flora," and his distinguished countryman, Dr. Schlich. There was also Dr. Cleghorn, of Madras; the late Dr. Stewart and Mr. Baden Powell in the Punjab; Messrs. Pearson and Forsyth in the Central Provinces; Beddome and Campbell, Walker in Madras, Dalzell and Shuttleworth in Bombay; and Seaton and Ribbentrop in Burmah. These have struggled to preserve our forests with a considerable measure of success; they have endured many toils, and risked their health, some of them even losing their lives in the service of the forests of India.

In conclusion he ventured to think this subject was worthy of the best attention of the Society of Arts.

In reply to the invitation of the Chairman, Mr. Andrew Cassels, who invited discussion Dr. Cleghorn stated that he had been much interested by Sir Richard Temple's graphic description of the forests of the Indian Empire, and the results of 20 years' departmental administration. It was extremely desirable that correct information should be promulgated on this important subject, and no one had wider and more general knowledge than Sir Richard Temple, who had steadily given the weight of his great influence to Forest Conservancy, and his commendation was most gratifying to an old forest officer. The department was formed in Burmah in 1855; Madras, 1856; Upper India, 1861; and the First Forest Act in 1864, amended in 1878. He referred also to the evils of denudation, due in a measure to the ramification of railways, which for fuel alone exhausted the forests for miles on either side.

Sir J. Fayrer expressed his tribute of admiration for the encouragement Sir Richard Temple, had always given to the science of forestry, than whom no Government officer had done more. On sanitary grounds he argued on behalf of the preservation of the forests.

Sir W. Robinson did not think much of the climatic consideration, and thought that the Government should act with great caution so as not to trench upon the rights of the people.

Mr. Bottley thought that the extension of agriculture in India should be encouraged in every way.

A vote of thanks was passed for Sir Richard Temple's interesting lecture, and the latter in returning thanks said that one twenty-fifth of the empire was under forest conservation, but that area, instead of being too much, was too little. He added also that it was for the welfare of the natives these regulations were made, and that there was a very large quantity of unreserved and village forests.

"MHOWA," OR "MAHWA," AN INDIAN FOOD-TREE.

By C. G. Warnford Lock.

THE problem of ensuring a sufficient food-supply for India's millions, cannot yet be said to be satisfactorily settled, though much has been done to avert future famines. Some remarks upon the *Singhara* nut, a highly important article of diet among numbers of the natives of India, appeared in the *Journal* of January 31st, 1879 (No 1367, vol xxvii., p. 174). An equally deserving subject is the produce of the *mhowa* tree.

The name *mhowa* which is spelt by Europeans in at least a dozen different ways, is applied, it would seem not only to *Bassia latifolia* the most important species, but also to *B. longifolia* and *B. butyracea*, whose fruits are likewise edible. The singularity of the genus consist in the fact that besides offering eatable fruits, their fleshy deciduous corollas are largely employed for the same purpose and in point of fact, constitute a staple and sometimes almost the only article of diet available to the poorer classes of Indian natives during several months of each year. *Bassia latifolia* is abundant in all parts of Central India, and is cultivated in many other districts.

Towards the end of February or the beginning of March as the crop of flowers approaches ripeness, the corollas, becoming fleshy and turbid with secreted juices, gradually loosen their adhesion to the calyx, and fall to the ground in a snowy shower. The duty of collecting the fallen blossoms is chiefly performed by women and children; at dawn they may be seen leaving their villages, with baskets and a supply of water for the day's use. Before the crop has began to fall, they take the precaution to burn away the grass and leaves at the feet of the trees, so that none of the blossoms may be hidden when they fall. The gleaners generally remain under the trees all day alternately collecting the crop, and sleeping, and the male members of the family visit the trees once or twice during the day in order to carry away what has been collected. At night bears, deer, and other animals visit the trees to take their share of the crop. At early morning and late evening the less frequented trees on the borders of the jungles attract numbers of jungle fowl and pea fowl. Cattle are also very fond of the flowers, and cows' milk has in consequence at this season a strong flavour of *mhowa*.

It often happens that the collectors come a considerable distance, in which case they erect with the branches of the *sâl* tree (*Shorea robusta*) a temporary encampment of huts, in which they live until all the crop is gathered in. In front of each of these huts a piece of ground is made quite smooth and hard for the purpose of spreading out the flowers to dry in the sun. When perfectly dry they have a reddish brown colour and are reduced to about a quarter their original size and half their original weight. It is a custom with some of the natives before spreading the flowers out to dry, to pull off the ring of minute foliaceous lobes which crowns the fleshy corolla. It is very difficult to obtain any trustworthy statements as to the yield of the trees. A first-class tree, it has been said will continue to shed its blossoms for 15 days, at the rate of 120lbs. a day; but this estimate is probably double what it ought to be. The rent of trees varies with their abundance in the district, the quality of the preceding rice harvest and various other circumstances bearing upon demand and supply. The extreme prices ascertained by Mr. V. Ball of the Geological Survey to have been paid for permission to collect, in various places were *2d.* and *4s.* The saved crop varies equally in price, the extremes being 120lbs and 480lbs. for a rupee (*2s.*) but when, as is most frequently the case, the exchange is made in kind, the merchants give only a small quantity of salt, and 6 to 8lbs of rice, for the maund (80 lbs.) of *mhowa*. During the famine in Manbhoom, a rupee would purchase only about 24lbs.

Some authorities state that two maunds of *mhowa* will furnish a month's food to a family of two parents and three children. It is, however, seldom eaten alone, being mixed with the seeds of the *sâl* tree (*Shorea robusta*), or with the leaves of jungle plants; sometimes a small quantity of rice is added. When fresh *mhowa* has a sweet taste with an odour somewhat suggestive of mice; when dried it presents some resemblance to inferior kinds of figs. Cooking renders it vapid, and utterly devoid of flavour. On distillation, the newly-dried flowers yield a highly intoxicating spirit, called *daru* which is generally diluted with five to ten times its bulk of water and is then sold at the rate of about 1½d. a quart. Its odour in most offensive to Europeans, but British soldiers have been known to secure intoxication by drinking it with held noses. By careful distillation, it is possible to get ride of the essential oil which causes the unpleasantness. As much as six gallons of proof spirit have been got from one cwt. of the flowers. The rectified spirit when placed in oak casks, takes a yellowish colour and is preferred to high class Irish whiskey. Analysis shows it to be wholesome. From the seeds is expressed a kind of oil, which is used for cooking purposes, for admixture with *ghee* (clarified butter), and for lighting and soap-making.

The tree thrives in poor stony ground, and might therefore, be cultivated on land not available for other crops. Though the natives protect such trees as exist, they do not seem to take any steps to increase the number. The yield of followers is proverbially regular from year to year. When dried, they will keep for almost any length of time. The large proportion of sugar (50 per cent.) contained in them has attracted the attention of agriculturists in this country, who see in them a valueable cattle food; and Messrs. T. Christy & Co., of Fenchurch-street, are already importing them for that purpose.—*Society of Arts Journal.*

THE *mahwa* tree (*Bassia latifolia*) is such an important Indian tree that it is satisfactory to find there is no chance of its becoming scarce. We gather this information from an official letter from the Chief Commissioner of the Central Provinces to the Government of India, in which he says that, as a general rule, the *mahwa* tree is not destroyed by the people. It is too valuable for its produce to be cut down and sold as timber; ordinarily the trees cut down are those that have ceased to bear fruit. The diminution in *mahwa* trees over considerable areas results from the enormous extension of cultivation there has been during the past fifteen or twenty years. They have disappeared in common with other forest trees. Of the *mahwa* trees, however, many

are left, and these are seen now in the midst of cultivation. Being valuable, they have been spared when other trees have been cut down. But no seedlings grow up in the cultivation, and there are therefore no young trees. With the view of ensuring the preservation of the tree in village areas, the *mahwa* has been included amongst trees which proprietors prohibit from being cut down without proper authority. It will be remembered that the fleshy flowers (not fruit) of this species constitute an important article of food.—*Gardeners' Chronicle.*

GROWTH OF TIMBER TREES.

A PAPER was read by Sir R. Christison at the last meeting of the Edinburgh Botanical Society upon the "Growth of Wood in 1880." In a former paper, he said, he endeavoured to show that, in the unfavourable season of 1879, the growth of wood of all kinds of trees was materially less than in the comparatively favourable season of 1878. He had now to state results of measurements of the same trees for the recent favourable season of 1880. The previous autumn was unfavourable for the ripening of young wood, and the trees in an unprepared condition were exposed, during a great part of December 1879, to an asperity of climate unprecedented in this latitude. This might have led one to expect a falling of in the growth of wood, and it appeared, from comparison of measurements that with very few exceptions, the growth of wood last year was even more below the average of favourable years than that of the bad year 1879. Thus, in fifteen leaf-shedding trees of various species, exclusive of the oak the average growth of trunk girth in three successive years was—1878, 8-10ths; 1879, 45-100ths; 1880, 3-10ths and-a-half. In four specimens of the oak tribe, the growth was—1878, 8-13ths; 1879 77-100ths; 1880, 51-100ths. In twenty specimens of the evergreen Pinaceæ the growth was—1878, 8-10ths; 1879, 7-10ths, 1880, 6-10ths and-a-half. After giving details in regard to particular trees, Sir Robert stated, as general deductions from his observations, that leaf-shedding trees, exclusive of the oak, suffered most; that the ever green Pinaceæ suffered least; and that there was some power of resistance on the part of the oak tribe which was remarkable, the power of resistance of the Hungary oak being particularly deserving of attention. In another communication on the "extent of the season of growth," Sir Robert stated as the result of observations on five leaf-shedding and five evergreen trees, that in the case of the former, even in a fine year the growth of wood was confined very nearly, if not entirely to the months of June, July, and August; while in the case of the latter growth commenced a month sooner, terminating, however, about the same time. Mr. A. Buchan said it was proposed that the inquiry should be taken up more extensively over Scotland.

AVENUE PLANTING IN THE MADRAS PRESIDENCY.

THE attention of taluq officers in the Chingleput district was lately directed by the Collector to the subject of avenue planting and to the necessity there was for Tahsildars, Sub-Magistrates Revenue Inspectors, &c., inducing villagers not only to plant avenues in the borders of their lands, but to encourage the planting of useful fruit trees. In the southern districts and along the great trunk roads between Madras and the towns south of Chingleput, large mango, jack, and other fruit trees may be seen spreading their lofty branches, and under their shade, and especially under the "sacred banian," many a weary traveller halts for the day or night, cooks his food, makes his *poojah*, rests a while and resumes his journey. The Local Fund officers and the revenue subordinates exercise some supervision in this branch of their work, so that the trees may be preserved and their fruit sold for the benefit of the sircar. In some districts, the produce of the jack, mango, and tamarind trees is given out on contract, and the returns form a not unimportant item in the village accounts. In the Chingleput district the roads leading to the Mount, Palaveram Poonamallee, Villacheri, and other distant villages, are lined with tamarind and mango trees, which not only afford shelter to the traveller, but the produce of these trees is sold for the benefit of the Government and in many places, passengers avail themselves of the fruit. The idea of planting these trees in the distant suburbs of Madras is a commendable one, and shows that in days long past the European and native district officials were not blind to the interests of those who were to come after them. But in our own day, is anything being done to preserve these avenue trees, to replace those that have decayed or to plant fresh ones where necessary? It is to be feared that very little is being done in this direction. In the town of Madras, the Municipality are planting avenues with *neem, poorsaram, banian*, and other trees. The last named, though a shady tree and well able to withstand the effects of wind and weather, is destructive in this way. The fruit it produces, popularly known as the Indian fig, is eaten by crows, kites, and other birds, and the seeds are dropped on house-tops. These germinate so rapidly that one not infrequently sees banian trees growing on the top of houses or from the cracks in garden walls. These plants take such firm root in walls that they cannot be removed without difficulty. We think, therefore, that the best description of avenue trees which the Municipality may advantageously plant in Madras and the suburbs is the *jack* and *mango*, which, in addition to affording shelter to pedestrians, supply delicious fruit which may be sold and the proceeds credited to Municipal funds. In the districts the Local Fund Boards, Municipalities, revenue officers, and tahsildars, to whom are entrusted the duty of improving villages and planting topes, may well follow in the footsteps of those who preceded them, and by planting useful fruit trees, they will not only follow a wise and beneficial course, but will lay the seeds of what will, in future years, prove an important source of revenue.—*Madras Standard.*

THE FORESTS OF AMERICA.

MR. T. MEEHAN states that "in the States of Virginia, Tennessee, and North Carolina, there are, at the present time, millions of acres of magnificent forest trees. Among these are white oak, red oak, and the tulip poplar, in immense quantities; with a great quantity of species, useful but less known, used in the leading arts, such as beech, birch, elm, sweet gum, black or sour gum, buttonwood, linden, cucumber, and other magnolias, ash, sugar, and other maples, locust chestnut, and horse chestnut, walnut, and hickory, enormous sugar berry trees, and dogwoods larger than in the north, besides many others interesting to the botanist, but for which the special uses have yet to be found. Besides these, there are among the resinous trees immense quantities of the yellow pine *Pinus tæda*), bull pine (*Pinus mitis*), and post or Jersey pine (*Pinus inops*), which grow up into forest of straight trees, very different from what we find them in New Jersey and Pennsylvania. Besides these are Hemlock spruce in some quantity, white pine in less, and in still smaller quantities balsam fir (*Abies frasers*) and black spruce (*Abies nigra*.)

GARDEN.

ROSES IN POTS.

THOSE who contemplate beginning the culture of the 'queen of flowers' in pots, cannot choose a better time to make their start than the present month. From the middle to the end of October is the best period of the year for transplanting roses, either in the open ground or in pots. Growth is finished, and the plants, though leafy and green, are hardened, and disposed to go to rest. They will therefore receive no check in being transplanted, while their tendency to rest is accelerated by the treatment, and the plants are rendered better fitted to withstand the rigour in winter in our climate on account of the additional hardening induced by the process.

It is altogether a mistake to suppose the falling off of the last leaf must be waited for before transplanting roses or any other deciduous plant. If the wood is not soft and sappy, it matters little how many leaves remain on the plant. The more the better, as a general rule, because the leaves while they remain on the plant will help materially to establish it in its new position by their aid in the production of new roots.

But it is more with regard to establishing roses in pots than in the open ground that we have to do in this paper, and we say again now is the best time. Everything is in favour of this early start. If the plants have to be selected from a nursery stock, or from the stock of a friend, or your own store of cuttings or plants bought in last year, the best can be selected and potted up, before they are appropriated by any one earlier astir than yourself in the matter. The first thing to be well informed upon in connection with this step is the selection of the right sorts, or those that succeed best in pots. If possible, and by starting early the possibility is reduced to certainty, let only sorts that are well known to succeed in pots be chosen, and let them be chosen also upon their own roots, rather than budded or grafted on the manetti or the briar stock. There are very few varieties that are not superior on their own roots, in point of durability and floriferousness, to those that are grafted or budded on the stocks above mentioned. They are hardier also, and better adapted to variations of soil, than when budded or grafted on any stock whatsoever. But should the plants not be obtainable on their own roots, there is no help but choose them, the best that can be had, on the manetti or briar stock. The latter is preferable to the former for pot culture, as indeed it is for any method of culture, being more hardy and vigorous.

When the plants must be selected from those on either of these stocks, let them be potted low, that is, bury the roots so that the base of the bud or graft shall be an inch or more under the surface of the soil. If this is attended to, the plants will soon be on their own roots, because roots will quickly be emitted from the union betwixt the stock and scion, and thus the plants will by-and-by be independent of the stock altogether. In order to attain this the more fully, choose plants with short stems, those which have been grafted or budded low on the stock, for, as it is undesirable to use a larger sized pot than one of 6 inches diameter, the stock should be short enough to be potted so low in a pot of the size named as that the base of the scion will be well covered. The compost should consist of rough, fibry loam. To this may be added about a third of a peck of bone meal of the best quality. The soil should be pressed firm, but not rammed solid, a practice recommended by some, but which is injurious to the plants. When potted the surface of the pots should be sprinkled with water and then plunged to the rims in coal ashes in the open air. In this position they may be allowed to stand till frost becomes frequent and threatens to be severe, when they should be placed in cold frames, where they can be protected from frost by means of mats or straw. In fine open weather let them be freely aired; indeed, the lights should never be kept close except in severe frost, or to exclude rain and snow.

As we are describing the treatment for plants that have just been potted up from the open ground, which so far is identical with that required by established plants, we must now note a difference which becomes necessary as to the starting of the plants into growth in spring. It should be borne in mind that these newly-potted plants will not bear being forced the first season. It is often done, but never without crippling the vigour of the plants. They should be allowed to start into growth in the natural course, giving them no more excitement than may be obtained by the protection which a cold frame affords. Before growth commences the plants must be pruned. Hybrid perpetual roses should be cut well back, leaving only two or three buds at the base of each shoot. Tea roses should not be cut back so severely, but should be pruned into firm well ripened wood in any case. When growth has started, great care must be exercised to prevent cold frosty air getting into the frame; nothing is more injurious than checks at this stage of the progress of the plants. Be careful also in watering neither to overdo nor underdo the supply. The syringe should not be used while the nights are cold and frosty, but as soon as such weather is past let the plants have a dewing over twice a day. And as the days and nights become warm, let more air be given, so that sturdy, healthy growth may be secured. When the plants have filled their first pots with roots, shift them into others a size larger, using the same compost, by and by, when these also are filled with root give liquid manure twice or thrice a week. The lights should be taken off, or better still, the plants be plunged in manure or leaves in the open ground. In this way splendid plants may be got up in one season's growth for forcing the following season.

The following are among the best varieties of roses for pot culture:—Abel Grand, Achille Gonod, Alfred Colomb, Anna, Alexieff, Marie Baumann, Victor Verdier, Centifolia Rosea, Bessie Johnson, Charles Verdier, Annie Laxton, Coquette des Blanches, Charles Lefebvre, Docteur Andry, Charles Margottin, Jules Margottin, Edouard Morren, Dupuy Jamain, Baroness Rothschild, Glory of Waltham, Senateur Vaisse, Madame Lacharme, Duke of Wellington, Hippolyte Jamain, La France.

ORANGES.

FOR a time when in England the orange was not—we must go back far into the mists of antiquity. As early as the year 1290, it is recorded that seven oranges (*poma de orenge*) were landed at Portsmouth from the cargo of a Spanish ship, but for two centuries after that there does not appear to have been any particular commerce in them in this country. Then they became an important item in our imports, Billingsgate being then as now the great landing-place for them. The Chinese claim the orange as a native fruit, and though as Mrs. Bayle Bernard points out in "Our Common Fruits" there being no reference to it in the travels of the accurate and observant Marco Polo, has led some to doubt this, yet it is more likely that he may have overlooked or forgotten it than that it should have spread so widely there and no record remain of its introduction had it been transplanted thither. So thoroughly, too, was it formerly identified with that country that the sweet fruit was once universally known in Europe as the Chinese orange, and it still bears that name in America and even in India. A large part of our present supplies comes from the Azores; but Spain, Portugal, and Sicily contribute immensely, and send us their crops earlier than do the Azores Islands. Particularly large is the importation from Valencia, which is one of the busiest sea ports and the most thriving of Spanish cities. But the Azores—and especially St. Michael, the largest of the group of the nine islands—furnish us not only with vast quantities, but the fruit is of a superior character, though we often get other oranges when we innocently buy what are represented to be "sweet St. Michael's." From this island there is a regular trade by means of steam vessels, each carrying 10,000 boxes or more, and their arrival in the neighbourhood of Billingsgate creates a busy scene; the porters with huge 'knots' on their heads, going to and fro as fast as they are able between the vessel and the fruit-brokers' warehouses in Pudding-lane, and the surrounding thoroughfares, where the fruit is sold by auction three or four times a week.

ORANGES IN JAPAN.

THE orange crop in Kiushiu has been unusually large this year. From the two townlands of Arita and Unami in that province, about twenty thousand boxes of fruit have been sent daily to the Osaka and Kobe markets. The numbers of oranges in a box depends of course on the size of the fruits—that of the boxes being generally fixed—but we shall not be far wrong if we estimate it at one hundred and fifty, at which rate the consumption of the Kobe and Ozaka fruit eaters would amount to some three millions of oranges per diem. But indeed eggs and oranges represent something more than mere edibles in Japan. They are the messengers of courtesy, he very rank and file of that intrinsically worthless but morally inestimable army of gifts from which all the outposts of Japanese amity and conventionality are garrisoned. Abolish baskets of oranges and boxes of eggs from the region accessible to coppers, and you shall subject the social existence of this country to a loss not less paralyzing than that of the jacket button, without which its owner was not at liberty to construe Horace. Oranges deftly piled up in plaited pyramids and eggs neatly pillowed in a bed of husks, do not convey much from the donor or confer much on the recipient, but in the eyes of a Japanese they are bulwarks of that very material old hospitality which forbade friendship to be ever empty-handed, and taught at the same time that the value of a gift is measured by its intention, not by its quality.

OPERATIONS FOR APRIL.

I.

IN HILL STATIONS.

THE FLOWER GARDEN.—All plants intended to flower in summer should be sown now. Another sowing of hardy annuals should be made where they are to remain.

Mignionette and Stocks may be sown now, and Biennials and Perennials transplanted. Sow Pansy and Heartsease. Propagate by cuttings Erythrina Crista Galli and Laurifolia. Bud Roses. Prune Roses not pruned last month. Prick in tender annuals to three or four inches apart in a fresh hot-bed, or thin them out. Sow half hardy annuals.

THE VEGETABLE GARDEN.—Jerusalem Artichokes may yet be planted out, and plant offsets of Globe Artichokes. Sow Parsley and Spinach, and plant Potatoes for main crop. Sow Turnips, Carrots, Cabbages, Cauliflower, Knol-Khol, Peas and Lettuce, Marjoram, Savory, and Thyme.

II.

IN THE PLAINS.

THE FLOWER GARDEN.—Store all bulbous plants the leaves of which have died down. Plant Achimenes in shallow pans or ring-pots, and water well.

THE VEGETABLE GARDEN.—Very little can be done now, but water well such vegetables as may remain and Asparagus.—*Indian Amateur Gardener.*

TEA.

A RANCHI correspondent writes :—"Tea planting has proved eminently successful in Chutia Nagpore ; and it is a fact worthy of record that the first efforts of a native gentleman I allude to our worthy citizen, Baboo Khettra Chundra Ghose in this direction, have been crowned with deserving success." The uplands of Chutia Nagpore seem to be favourable to the growth of tea. Coffee, too, is successfully grown here and the gentleman referred to owns the largest coffee garden in Ranchi.

THE Batavia *Dagblad* draws attention to the fact that the Government Java cinchona bark brings in the European market an estimated average price of 2s. 2d. per English lb., while Jamaica cinchona bark brings an average of 3s. 9d. per lb.

THE *Produce Markets' Review* speaks of low class teas tending to keep down prices at home, could not our planters see their interest in confining themselves more to the fine qualities in future, thus they would raise the name of Indian teas, keep done stocks in London, and considerably help the market generally.

"INDIAN tea continues to be largely offered, and owing to a less active demand and to the poor quality of the bulk of the supplies, prices have been more favourable to buyers. The increasing proportion of the commoner broken sorts has for some time exceeded the demand, and has had a depressing influence on their values. Although the consumption of the commoner descriptions of Indian teas is large, it has been materially checked by the exceptionally low prices which similar grades of China growths now fetch. There appears every prospect of abundant supplies of all sorts of common tea, both from India and China, and a considerable increase in the demand may be necessary before a material rise in the values of such descriptions can take place. The depreciation has extended to the Souchong, Pekoe Souchongs, and the less desirable medium parcels, while the eager competition for Teas possessing quality and strength has caused the recent firm prices to be maintained for the latter kinds. At the public sales 11,712 packages were brought forward, but except for the really finer sorts the tendency of the market throughout was adverse to importers. Two small invoices of Java teas have been offered, but the quality was inferior."

BULKING.

THE frequent and well-founded complaints of irregularity in Indian teas bulked in the London warehouses, are still a constant source of annoyance to the trade, and must lead to the conclusion that the system of "bulking" adopted is a faulty one.

The "bulking" of tea in India has hitherto been carried on to such a small extent that a comparison between the outturn of breaks bulked there and at home can scarcely yet be made, while the absence of regularity in both the size of the packages and the quality of the tea too often apparent in parcel offered here as "bulked in India" shows that the difficulty, from whatever source it arises, still remains to be overcome on the other side.

If we now turn to the produce of China, we see a very different condition of things. China tea is not bulked in this country, and such a thing as a claim for regularity is practically unknown. It would be well, therefore, to look at the plan adopted by the Chinese, which works so satisfactorily, and which, moreover is extremely simple, with a view to judging of the practicability of applying it to Indian tea.

The method is as follows :—Immediately after the final firing, and while the tea is still hot, it is spread in even layers, two or three inches in thickness, one on the top of the other, at the end of a godown, the height and breadth of the heap being according to the size of the parcel, or chop, as it is there called, to be made. An ordinary wooden rake is then drawn down the face of the pile, thus raking an equal quantity from all the layers, and securing (the all important point) a thorough mixture of the tea. As fast as it raked down it is shovelled into baskets and weighed, an equal quantity being put into each chest. Then, while still warm the tea is packed and soldered up at once. The chest being made of an even weight, it will thus be seen that by this careful system, irregularity both in quality and tare is avoided.

The principal difficulty that the proprietors of London warehouses might find in following the above plan is the limited space which is often at their disposal, but surely the end attainable must show the desirability of overcoming this and of giving up the present unsatisfactory process. It would also be well if more care than is now used was exercised in treading back the tea into the chests. Fine broken Pekoes, for instance, are often much injured in appearance, and consequently depreciated in value, by the treatment they receive.

In India, where space is not of so much object as in this country, the Chinese mode of "bulking" might well be carried out, and we are strongly of opinion that if the owner of gardens can see their way to making arrangements for equalising the size of packages and thoroughly mixing their teas before packing, thus doing away with the necessity for bulking at home, the article will keep better and the Indian tea trade will be carried on with more satisfaction and more profit to all concerned.

THE TEA TRADE.

IN the years 1836 to 1848, the monthly consumption of tea of all kinds was between only 1,000,000lbs and 4,000,000 lbs ; by the year 1868 it had increased to 7,104,000lbs ; and since then it has been nearly doubled to 13,500 000lbs. ; the amount estimated for 1880. From 1860, when Indian tea claimed greater attention, to 1865, the average monthly consumption of that growth increased from 100,000lbs. to 250 000lbs. ; in 1868 it had reached 823 000lbs. ; in 1871 as much as 1,163,000lbs. ; by the year 1876 it rose to 2,345,000 lbs ; and so on up to the present time, when it is computed to be about 4,000,000 lbs.

CHEMISTRY OF TEA.

A GERMAN chemist, I. M. Eder, has been investigating the chemical composition of tea as it leaves the hands of the Chinese. It would be too long here to follow the author through all the details of this inquiry, but we may arrive at once at the general conclusion, *viz.*, that the tea leaf is very highly adulterated by the Chinese, independently of any fraudulent admixtures which it may receive at the hands of the dealers. The Chinaman's most common offence is that of the mixing old teas with the newly plucked leaves, the worst with the better sorts, &c., and calling these mixtures by certain fancy names but not much importance is attached to this by our author, neither to the process of scenting by keeping the tea in contact for a certain time with strongly odoriferous flowers, and then removing it. There is no tangible adulteration in these practices, but beyond this there is actual adulteration to a considerable amount, and Dr. Eder divides these adulterants into four classes :—1. Mineral substances for increasing the weight. 2. Mineral colouring matters. 3. Organic

substances for increasing the weight; and 4. Organic colouring matters and astringents. The latter, which are difficult to detect, constitute a very noxious adulteration, and will end by driving tea out of the market altogether if persevered in. It is already well known that pure tea is tolerably astringent, and that persons past the meridian of life who indulge in tea more than once a day, are apt to suffer from the effects of constant constipation. Of course these baneful effects will be still more increased by the addition of astringent organic matters and vegetable colouring matters possessing the same injurious qualities.

The Chinese sometimes mix the leaves of other shrubs with tea but this is easily discovered (if not at first sight) by making an infusion of it into which put a grain and-a-half of blue vitriol (copperas) if it be good genuine *green tea* and set in a good light, it will appear of a fine light blue; but if it be adulterated green yellow, and black colours will be distinctly seen.

After this fraud was detected the Chinese *dyed* the leaves of damaged and ordinary *green tea* with Japan earth (*terra japonica*) which gives the leaf the infusion, and the tincture the colour of *bohea*. This is to be detected in many ways; first, a less quantity of this dyed tea gives a deeper colour to the same proportion of water than if it was good. 2. The colour it gives the water will also be of a reddish brown, whereas it should be dark. 3. When the leaves have been washed by standing a little, they will look greener than good *bohea*. 4. This dyed tea is generally much larger, therefore it is better to buy the small-leaved tea. 5. The infusion, which should be smooth and aromatic to the palate, tastes rough, and more harsh. 6. If milk be poured into it it will rise reddish instead of dark or blackish brown. 7. A little sulphate of iron put into this liquid will turn it light blue, which otherwise ought to be of deep blue, inclining to black. 8. Water of ammonia makes the good tea of a deep brownish yellow after it has stood a while, like new drawn tincture of saffron, but it has not that effect in bad tea.

Green tea is also counterfeited by dyeing bad *bohea* with green vitriol, but this may be detected by adding a little powdered gall to the infusion, which will turn it immediately black; spirits of hardshorn will make it of a purple colour, and cause a slight precipitation, instead of a deep greenish yellow, when it has stood for about six minutes.—*Monthly Magazine.*

THE INCREASED CONSUMPTION OF INDIAN TEA.

AFTER a long series of bad years, an opening in the clouds is observable in the tea industry. Such a prospect must be very pleasant to those who have been in the very slough of despond for such a length of time. Hope deferred maketh the heart sick, and the unfortunate tea shareholder has had enough to make him sick almost unto death. However, "the darkest hour is that before dawn," and so it has been in this connexion. Low as prices have been for a number of years, they seem to have reached their nadir about three months ago, when a check was felt, and a slow, but apparently steady, increase set in. During the past year an intelligent effort was made to find new markets for our tea, and a considerable amount of success resulted in Australia. That, however, cannot be said to have influenced the home market yet, consequently the outlook is all the more hopeful, because it is entirely confined to the English market. This is only one point, in connexion with this subject, which wears an encouraging aspect. It might, for instance, have been due to some accidental condition of the market, such as a deficient supply; but this is not the case, as the imports for the whole year (1880) amounted to 45 million pounds, against 38½ and 36 million pounds in 1879 and 1878 respectively. We must, therefore, look for another cause. It might also have arisen from the supplies from China being of inferior quality, but this is also not the fact, as the London brokers' reports tell us that the Chinese are making an effort to recover their lost ground, and that, in consequence the recent arrivals from China have been of much better quality than usual. Impoverished stocks have nothing to do with it, for we find stocks to have stood at 20 millions lb, on 31st December 1880, as against 17¾ and 14½lbs. in 1879 and 1878 respectively. No, the change has set in from the best of causes, an increase in consumption, and this is the most hopeful feature of the event. In 1860, the consumption of tea, per head of population, was, in the United Kingdom, 2·622 and ·038 lbs. for China and India respectively, and both increased till the year 1875, when the figures stood at 3·728 and ·712 lb. respectively. As regards Indian tea, the increase has continued up to date, while the deliveries of China tea have practically remained stationary since that time. The consumption of Indian tea per annum, per head of population, has been as follows, since 1875:

	lbs.
1875	·712
1876	·803
1877	·836
1878	1·087
1879	1·037
1880	1·269

During the last four months of 1880, the deliveries were at the rate of 4 million pounds per month, which was equal to an annual consumption of 1·891 lbs. per head, or 91 per cent over the consumption of 1875. This ought to reduce stocks and this reduction will be aided by the fact, that during the past three or four years, the low prices obtaining for tea have discouraged the extension of cultivation, and this, in turn, will keep down the heavy ratio of increase in production, which has been characteristic of tea garden operations for some time. The efforts that have been made for the last four or five years to introduce Indian tea to the British public in a pure and unmixed state, are now beginning to bear some fruit, and to the fact that, in many towns and centres of population, Indian tea can now be had in an unmixed state, this increase in consumption is largely due. It is hard to understand how it could be otherwise, as, if a hundred people drink pure Indian tea for a month ninety of them will keep to it if they can procure it; hence, a large increase in consumption has resulted from the introduction of Indian tea in such a form that the consumer could obtain it genuine.

Now that the tide has turned, it will be the tea manufacturers' fault if the industry ever falls in public estimation. That the desirable end of keeping Indian tea in a high place in the favour of the public may be assured, the greatest care must be taken that it should be good and that there should be no difficulty in the consumer obtaining it pure and in such quantities as he may desire. This latter has been the desideratum in days gone by. The consumer was perfectly willing to pay a fair price for the article, but there existed no means of his obtaining it genuine unless he purchased a chest which was an original package. Now that he can obtain a single pound of it, he may be depended on as a good customer, so long as the manufacturer keeps up the quality. It is not necessary perhaps that we should comment on the effects of rasping tea on the consumer. This has been discussed *ad nauseam*, and we are convinced that the planter is becoming alive to the importance of producing a delicately favoured tea suitable for drinking, without any mixture whatever. This granted the future of the Indian tea industry may be considered as assured.—*Englishman.*

COFFEE.

THAT the consumption of coffee in the United Kingdom does not shew any signs of increase is clearly shewn from the following table, which we extract from the *Ceylon Observer*:—

Summary of imports, deliveries, and stocks of coffee in the United Kingdom during the last thirteen years, from official records:—

	Imports	Deliveries		Stocks end Dec
		Home use	Exports	
	Tons	Tons	Tons	Tons
1880 ...	77,797	14 540	65 600	17,000
1879 ...	80 869	15 489	65 000	15 000
1878 ...	63 670	14 808	53 000	18,500
1877 ...	80 486	14 656	56 000	18.000
1876 ...	67 069	14 885	61,000	9 058
1875 ...	79 708	14 450	60 500	18,000
1874 ...	70,704	14 223	54 000	14,000
1873 ...	84,184	14,433	72 000	12,000
1872 ...	74 586	14,134	70 500	13 500
1871 ...	86,000	13 844	76,000	25,000
1870 ...	80,287	13 674	64 652	31.000
1869 ...	77 418	12,991	57,211	29,468
1868 ...	77,635	13,665	60,297	22,545

A NATIVE planter in Ceylon epitomizes the causes of loss in coffee planting under the following heads:—

1.—By unfavourable seasons at the time of blossoms.
2.—By leaf-disease.
3.—By buying lands on enhanced rates, also on borrowed capital.
4.—By putting up costly and permanent buildings.
5.—By paying very high salaries to managers, &c.
6.—By paying a heavy percentage for cash, credit, exchange, disbursement, &c.
7.—By paying tax to medical aid.
8.—By paying extra watchers to protect crop from villagers.

MR VAN MAANEN, of Salatiga (Java), the inventor of a process to dry coffee artificially by heated air, has sent round a circular to coffee planters in Java offering to make known his invention to them in case of sufficient support, at a remuneration of half a guilder for every picul of coffee produced on their estates in 1880. The Samarang *Vaderland* of the 15th January describes Mr. Van Maanen's process as simple, easily managed even by natives from no engineer being required, and refuse, such as coconut shells, bamboo, &c., may be utilised as fuel. The apparatus can deal with from 22 to 100 piculs of coffee in 24 hours. The coffee comes out of the apparatus perfectly dry without any injury to its quality, and the total drying expenses amount to only 6 guilder cents. per picul. The cost of setting up an apparatus for a product amounting to 2,000 piculs is 1,500 guilders, scarcely any repairs to it being afterwards required. These facts are certified by three managers of coffee estates who have experimented with the invention. In their certificates appended to the circular, they estimate the expense of drying 2,000 piculs of coffee by the ordinary method at 6,000 guilders, while by Van Maanen's process it will amount to only 175 guilders, thus at a saving of 97 per cent.

THE *Natal Mercury* mentions, as a curious fact that "Monkey Coffee trees" are flourishing on the estate of Mr. H. B. Wood, "Claremont," while on the same estate the pruned and tended coffee trees are decaying. Perhaps if inquiries were made, a very large proportion of the estates on the Nilgiris will be found to have originated in monkey seedlings. It is usual to collect these seedlings in the shola and form nurseries of the same. The seedlings are the product of the very best seed, as monkeys are choice in the selection of the fruit they pick off. The seedlings, if taken from the shola, before they become drawn and spindly, make excellent nursery plants.

THE WYNAAD LABOUR SUPPLY.

ON the 10th January, the Government of India wrote to the Government of Madras to acknowledge the receipt of their letter dated the 16th August last, submitting a memorial from the Wynaad Planters' Association. The Association requested that the interests of the coffee districts may be carefully considered by the Government of India in the impending changes connected with the rendition of Mysore. They specially desired, first that the future Government of Mysore may be brought to pledge itself to place no restriction on the Emigration of Mysore labor to the planting districts, and secondly, that the existing facilities for the execution in Mysore of the processes of British Courts may be preserved. In reply, the Supreme Government requested that the Secretary to the Wynaad Planters' Association may be informed that the Government of India will give due consideration to the point to which the memorial has invited attention, "although, in such a matter as the execution of processes, it may be difficult so to arrange matters that the existing procedure should not be in some degree affected by

the termination, in Mysore, of the present system of administration under the Government of India." The Association have addressed another communication to the Madras Government on the subject, as the Committee consider the reply of the Government of India "most indefinite, having regard to the imminency of the pending change and the interests at stake."

LIBERIAN COFFEE IN ITS NATIVE *HABITAT*.

WE are indebted to a subscriber for bringing under our notice the following passage from a book published in 1854, entitled "The Revelations of a Slave Trader." Captain Canot, the trader in question writing of the Colony of Liberia, says:—

"Coffee trees grow much larger than on this (the western) side of the Atlantic; single trees often yielding sixteen pounds, which is about seven more than the average product in the West Indies.

"I wish to confirm and fortify this statement in regard to the value of coffee culture in the West African colonies, by the observation of Dr J. W. Lugunbeel, late colonial physician and United States agent in Liberia. The doctor gave particular attention to observations and investigations respecting coffee culture in Liberia. 'I have frequently seen he says, isolated trees growing in different parts of Liberia which yielded from ten to twenty pounds of clean dry coffee at one picking, and however incredible it may appear, it is a fact that one tree in Monrovia yielded four and a-half bushels of coffee in the hull at one time, which when dried and shelled weighed thirtyone pounds. This is the largest quantity I ever heard of, and the largest tree I ever saw, being upwards of twenty feet high and of proportionate dimensions.' The doctor is of opinion, however, that as the coffee tree begins to bear at the end of its fourth year, an average yield at the end of the sixth year may be calculated on at least four pounds. Three hundred trees may be planted on an acre, giving each twelve feet and in six years the culture will become profitable as well as easy."

In the low-country of Ceylon the "Liberian" coffee begins to bear after its second, and freely after its third year; but the estimate of an average yield of ten cwts per acre (from 300 trees) in the sixth year is doubtless a fair one. Over small areas, that quantity has been realized in Ceylon, however, at an earlier date.

COFFEE PLANTING IN AFRICA.

THE *Norddeutsche Allgemeine Zeitung* gives a long account of an attempt which is being made by the Hamburg firm of Woermann to cultivate the coffee tree of Liberia by free negroes on the West Coast of Africa. The place selected for the experiment is the French colony of Gaboon. The execution has been put into the hands of Hermann Soyaux, author, of the well-known book, "Aus West Africa," who accompanied the first German expedition to the Congo coast in the character of botanist. Herr Soyaux has now been at work on the spot for nearly two years; his coffee plantation lies about a day's march inland from Gaboon on the Awandu. Beginning at first under adverse criticism and difficulty, he has succeeded in organising a band of nearly one hundred free negroes, who had to clear away the primeval forest with axe and fire, though they now have more scientific appliances at command, using electricity and dynamite for the felling of the huge giants of the forest. Many thousand coffee trees from Liberia have been planted in the clearing; attempts have also been made with coffee seed, and Herr Soyaux expects to send his first great crop to Hamburg in 1882. Herr Woermann supplies the colonists richly with machinery cattle, horses, and mules, being determined that the experiment shall not fail through lack of thorough testing. The French Government has acted with great kindness and consideration, freeing the German coffee farm from the obligation of paying the customary import dues. Meanwhile Herr Soyaux is not neglecting to make scientific use of his stay in this interesting district. He sends regular meteorological reports to the Leipzig Observatory, and has enriched the Hamburg Museum with many contributions.

MR. MARSHALL WARD'S SECOND REPORT ON COFFEE LEAF DISEASE.

(*Concluded from page 53.*)

SUMMARY.

IN conclusion, I beg to offer the following short summary of what appear to be the chief steps established. After referring at some length to the newly-discovered tenuip-shaped spore (*Pleulospore*) and its products, so far as I have been able to observe them, some stress was laid on the great importance of learning exactly what becomes of the *conidia* or small spores budded off from it. I then proceeded to state the results of a difficult task—the discrimination and relations of various filaments found on the coffee, and shewed that four different kinds occur all over, and that, partly from actual cultivation and partly from induction, I attribute to these no gentic relation with *Hemileia*. Nevertheless, from certain difficulties of manipulation not yet surmounted, the exact position of one form is left in some doubt, until certain facts are established: that this filament (springing from an oval septate spore, often tinged with olive) has anything to do with *Hemileia*, is very unlikely.

A considerable mass of positive evidence, however, was offered to prove that the ordinary papillate spores forming the main bulk of the orange-coloured rust, can convey the fungus from plant to plant in a simple manner: this occurs in observed cases as follows. A short, hollow tube grows forth from the spore on the leaf surface; on reaching a stomate it forms a vesicular swelling, the contents grow into the leaf, and there at length develope the coral-like mycelium of the fungus (*Hemeleia vastatrix*).

Having traced the fungus from a spore into the leaf, I devoted some paragraphs to an examination of what the mycelium does when in the leaf, and shewed that the discovery of an exhausting organ (*Haustorium*) explains how the contents of the cells, which ought to be employed solely for the nutrition of the tree become transferred to the fungus, serve it for food, and enable it finally to cast off myriads of spores which will (unless interfered with) reproduce the parasite as before. Arguments were then adduced to prove that a considerable effect is thus produced apart from the mere transference of material, that a disturbance of function must be taken into account. Some important deductions follow from the analysis of diseased coffee leaves, and are valuable especially as being made independently.

I then examined what is at present clear as to the leaf-fall so much complained of where the premature fall is caused by leaf-disease, what has been said above will explain how it is brought about. A number of effects of leaf-fall were then discussed, and the whole question shewn to be far from simple; but one easily understood result is that branches denuded of leaves may "die back" and exhibit the appearances so common on diseased trees.

In the form of an appendix I add more details.

I have still under supervision several experiments as to the application of remedial measures on a large scale, and am by no means unmindful of the bearing of the new facts upon these: of the practical and economic difficulties I need say nothing here, and the importance of a thorough knowledge of the parasite to be contended against is unquestioned. One fact seems to me to stand forth prominently in this connection—the papillate spores (which I have proved capable of directly conveying the fungus from one coffee leaf to another) can germinate on leaves lying upon the ground; I am assured by several planters that the removal of such leaves can be accomplished, and must urge the necessity of a thorough destruction of what is a certain source of propagation of "leaf-disease." The results of experiments shall be made known when decisive, but no doubt can be held as to the importance of the destruction of the spore-laden leaves. My thanks are tendered to the several gentlemen who have aided me thus far; and especially those who have enabled me to commence experiments, the results of which I am anxiously watching. Meanwhile, no trouble will be spared to thoroughly investigate and report upon the remaining phenomena of "leaf-disease."

I have, &c.,

December 1st, 1880. H. MARSHALL WARD, B.A.,
CRYPTOGAMIST.

APPENDIX.

The manner in which the results detailed respecting the filaments have been obtained may be generally summed up thus. Assuming that the mesh works of the fungi must obtain nourishment from the inorganic and other matters dissolved in the water on the leaves, since they form such copious growths thereon. I so arranged matters that they should grow in the same way under observation; thin slices of the coffee leaf were cut parallel to the surface, and examined in pure water, and when, after several trials, I had obtained a piece on which was the spore or filament desired, it was manipulated as follows.

Suspended in a drop of fluid from the under side of a thin glass plate which formed the transparent roof of a glass cell, the piece of leaf could be kept in its normal position, and supplied with air and moisture at will. All class parts were previously boiled in sulphuric acid, and washed with pure water, so that, with care very little risk of admitting foreign spores was incurred. The fluids used were similar to those tried in germination experiments, with particular reference to the kind of fungus.

The results were generally rapid and satisfactory: with the exception noted, the filaments grew in all directions into the special soup prepared for them, and as they extended clung to the moist under-surface of the thin glass roof. In course of time the copious network produced naked spores, and in some cases the perfect fruit proper of the species: I was thus furnished with the data necessary for conclusion as to the relations of these fungi. In most cases the more complex solutions yield the best results.

Similar attempts to persuade the coral-like mycelium to grow out into prepared fluids have totally failed so far; the piece of mycelium selected may remain for days in a state of quiescence, judging from the sharp outlines and vigorous looking contents, but appears too much adapted for special conditions of life to be thus cultivated in artificial solutions.

B.

To give an idea of the number of observations on which the foregoing results are based, I subjoin a list of notes compiled from my laboratory diary; only successful experiments are noted here.

Eleven experiments with the object of growing the coral-like mycelium in artificial solutions: no growth.

Forty-seven sowings of the yellow papillate spores have been made in various solutions (spores of various ages, dry, wet, &c.,) and on coffee; but germination, &c, as described. In some cases no germination occurred, the spores became emptied without forming tubes.

Twenty-one sowings of spores from various fungi found on the coffee leaf; the results are embodied in the report.

Thirteen successful growths of the filaments, referred to above, were kept under observation for periods varying from a few days to a month.

Fifteen sowings of the *conidia* of *Hemileia* were made in fluids and on coffee; in no case did the germination extend beyond the formation of a short delicate simple tube.

Twenty-two experimental sowings of various spores obtained from dead coffee leaves and various grasses on estates, &c., have given support to the conclusions so far arrived at.

C.

I owe the following to the kindness of Mr. G. Wall. A long glass-roofed case was divided into six compartments, open below: this was placed on the ground, and several seeds and young (diseased) plants placed in each. The contents were then treated as follows:—

No. 1 with caustic lime.
„ 2 with mixed sulphur and lime.
„ 3 received no treatment.
„ 4 with carbolic-acid powder.
„ 5 with purple Condy's fluid.
„ 6 with phosphorus suspended over waters.

The roof was then closed tight, arrangements made for a supply of water through tubes from behind: they remained closed from February 5th to June 2-th, when I examined them.

In no case had germination been prevented, and only in No. 4 were all the seedlings destroyed. No recent disease spots were discovered, though several old, worn out brown patches remained on some leaves; on these brown patches I failed to find any of the "black dots" so usually present on the upper side. All had filamentous networks belonging to several different forms; these occurred chiefly on the leaves. The young leaves and seedlings shewed no signs of "rust."

These are the chief results, carefully noted at the time: the experiment is by no means conclusive, since the case (No. 3), which received no treatment, was no worse off than the rest. The filaments may have been derived from insects carrying the spores—the soil below was unfortunately

not baked, and the absence of several other precautions rendered the result somewhat negative.

The chief point to remark is that no relation between the quantity of filaments and of disease was observable; any other inference must be drawn with great caution, and in the light of other facts.

D.

Mr. Hughes' "Report to Planters' Association" (pp. 112—113) states that the results of weighing selected, healthy, and diseased leaves were as follows:—

Weight of fully-matured leaves from three estates.

	No. 1—10 leaves each.		No. 2—10 leaves each.		No. 3—10 leave each.	
	Healthy.	Diseased.	Healthy.	Diseased.	Healthy.	Diseased.
Water	96	70	112	79	188	128
Solids	51	50	65	51	87	76
Total	147	120	177	130	275	204

He explains the large differences as due to differences in size and vigour. No. 3 being very large, and the diseased set very bad, while No 1 was a sample of inferior leaves. He accepts No. 2 as a representative sample, and believes the differences in actual weight are due to ravages of fungus.

The following table shows part of one on p. 148, giving details of analysis of partially dried healthy, contrasted with diseased coffee leaves. Ten leaves of each were selected as before.

	Healthy. per cent.	Diseased. per cent.
Mucilage, sugar, tanin, and other soluble matters	23·76	11·81
Woody fibre (cellulose), &c.	17·33	18 80
Albuminous and insoluble compounds	36·76	45·59

The fatty and mineral constituents appear to undergo little change in amount, but a comparison of the further analysis of ash is very interesting as indicating large differences in detail.

As example of the kind of leaf-fall now experienced, Mr. Mackenzie Laxapana, kindly furnishes me with the following details. The leaves fallen from a given patch of 160 trees were collected at intervals, dried in air, measured, and a sample bushel weighed.

1879.		Bushels collected.	Weight per bushel.	Calculated total weight.
November	1	74	4½ lbs.	333 lbs.
December	24	19	4 „	76 „
1880.				
February	25	68	3 very dry	204 „
July	18	37	4 lbs.	148 „
August	18	37	4½ „	166½ „
August	31	13	4½ „	58½ „
		248		986 lbs.

Now this amounts to little over 6½ lbs per tree for the ten months. *N.B.*—This is exclusive of prunings—or, per acre of 1,210 trees, he finds about 7,910lbs of leaves had fallen.

Mr. Mackenzie also weighed out ½ lb. of dry leaves and had them carefully counted: he finds 1,230 leaves, or 2,460 per lb.

If this represents a fair statement, we are driven to the conclusion that each tree of the coffee examined dropped on the average 15,990 leaves in the ten months.

I am convinced that these numbers are too high; but they will serve to shew that a great fall evidently occurs at times. The chief sources of error in the above experiment seem to me to be as follows:—

(1). In the rough air-drying of the leaves, uniformity cannot be secured.

(2). A sample bushel probably varies considerably in weight.

(3). A number of leaves will vary greatly in bulk and weight.

(4). Many difficulties in the collection—such as care that no soil, &c., is mixed, that all the leaves are from the given trees, &c., must be taken into account.

(5). Broken leaves take up less space, and much curled ones occupy more space than the normal.

But suppose we take a low estimate in all directions above: we have then 248 bushels collected, weighing say, on the average 3lbs per bushel. The total=744 lbs. Each lb. contains, say, 2,000 leaves. Even now the total number of leaves collected would be on the average (allowing only 4lbs. per tree) 8,000 leaves per tree fallen in less than a year.

F.

Through the kindness of Mr. G. Ross, I am enabled to give another experiment proving that a large fall of leaf may occur, although the results differ materially in detail. The leaves were collected from under 100 trees on a patch protected from wash by two roads, and from wind and rain by the wide spreading of the branches: little disease had shewn for over six months, and no prunings had fallen on this patch for nearly a year. The trees are old, and by no means thick, though at the time the fallen leaves were collected they were fairly clothed with a fine foliage. No crop to speak of had interfered with the estate of the trees. There were collected, after being carefully dried in the sun, 127 bushels fairly measured. Five separate weighings of a bushel of these leaves averged—a bushel weighed 1⅓lb.

A bushel of *selected* leave was then measured, the leaves were chosen so as to exclude all but unbroken ones. It required 1,300 leaves to fill a bushel box, and they weighed ¾lb. A similar result was attained on repetition.

This bushel of whole leaves was then crushed and broken up to some extent; the product now measured about ⅝ bushel. If we trust these results, it follows that *at least* 165,100 leaves were collected from below 100 trees, and we will assume that they represent the fall of six months, though probably a shorter time would be nearer the truth: from this must be accepted that the 100 trees dropped 330,200 per annum, for the fall is almost certainly not less in the north-east monsoon than in the south-west, when these fall.

Hence is inferred that 3,302 leaves per tree per annum fall on the patch in question, and is believed to be within the mark.

On one of the trees, selected as typical, were counted 2,628 leaves by stripping them off and placing in a sack; in the fresh state they measured 1½ bushel and weighed 4½lbs.

How far the differences in the estimates depend upon differences in size, weight, and number of leaves, or on differences in manipulation (drying, weighing, measuring, &c.,) will be subject for further inquiry.

G.

Mr. Anton, Pundaluoya, has been good enough to furnish me with the following data at my request. A number of diseased coffee plants, which had been established about a year, were examined; counting only those which were in a condition representative of the majority and neglecting all which had no leaves, as well as those in shaded, or otherwise favoured situation, the average number of leaves was as follows:—

500 plants had 2,544 leaves
500 „ 3,165 „

Or, in the former case, each plant averaged about five leaves; in the second example, about six. Considering all things, these numbers are far below the normal.

An analysis of these numbers will aid in forming a more exact estimate of the state of the plants, if it is borne in mind that a plant established for one year, bearing say only eight primaries, of which the lowest have eight leaves and the uppermost but four, might be expected to shew about 50 leaves at least.

101 plants had above 10 leaves each. Of these 9 had more than 20 leaves. No plant had above 25 leaves.

899 plants had less than 11 leaves. Of these 284 had 6 and upwards: the majority of these bearings 6. 116 had but a single pair of leaves.

H.

To satisfy myself of the fact that the wind conveys fungus spores from place to place, I suspended a glass slip (previously boiled in sulphuric acid and washed in pure water) for twelve hours over an open piece of ground. In one case the result was as follows:—

On a portion of the upper surface, ¼ inch square, I recognised twenty-eight individual spores, one mass of toruloid bodies, and a rather large fungus filament; in addition to these were larger or smaller pieces of amorphous organic matter, bits of cell wall, and inorganic particles. Crowds of brilliant particles (*bacteria, microgonidia,* &c.) and pieces of spider's web also occurred. In the twenty-eight spores counted, seventeen different kinds were noticed; one of these was a yellow papillate spore of *Hemileia*. These were caught in the slight dew formed during the very still warm night.

A more startling result was obtained by fixing a similar glass slip in the position of a leaf upon one branch of a coffee tree among several others; in this case I slightly gummed a square inch of the *lower* side. After 24 hours I examined the large drop of water attached to the gummed under side in the early morning; the preceding night had been windy, and a little rain had fallen.

The number of individual spores &c., of various kinds was too many to count. After placing a thin cover slip one inch square over the whole, I counted 820 in a space about ¼ inch square; of these 51 different kinds were sketched. There were 19 yellow papillate spores of *Hemileia*. I believe that 4,000 spores of various kinds at least could have been counted in the whole drop; many of these were no doubt due to the neighbourhood of several large trees.

I.

It may aid the forming of conclusions to give a short account of some observations to determine the following points, all of great importance:—

(1). How long it takes to construct a leaf.

(2). How long the leaf lasts on an average.

(3). What is the duration of a disease patch.

The results so far obtained appear to hold good for part of the year at least, but there can be no doubt that differences will occur *according to elevation, climate, and other causes; nevertheless it is necessary to obtain* and verify data of this kind by numerous observations. The greatest difference of unchecked opinion exists on the subject in Ceylon.

The means employed were simple: to tie different-coloured ribbons round certain twigs properly selected, and keep a series of notes taken every few days: by roughly mapping the leaves examined very accurate and minute notes may be kept. I select the following notes:—

On August 25th a bud was selected for examination, its two opposed leaves being just distinguishable.

August 30th.—The leaves have separated and, become of an olive-green or almost copper colour.

September 6th.—Now divergent from one another, with a coppery hull, each about one inch in length.

September 14th.—Nearly two inches long, still copper-colured, very thin. Growing fast.

September 30th.—More than three inches long: a small bud between now quite evident.

October 16th.—May be considered full-sized (four inches). The dark hue replaced by a bright green.

October 29th.—The first signs of disease appeared as two small pin-points on the right-hand leaf.

November 1st.—Now two yellow patches, but no spores, &c.

November 8th.—One patch is of a peculiar opaque yellow, the other (they are close together) has burst through, and is of a brilliant orange colour with fresh spores.

November 15th.—The one spot has become old and brown in centre, the other is vigorously producing spores.

November 21st.—Both spots are brown in centre: they remain of the same size and produce spores but slowly.

This experiment shews that it took seven weeks or so to complete a pair of leaves. The disease was established (no doubt from neighbouring old coffee, among which the tree was growing) within a fortnight after maturity, as two simple spots, which took about two days to ripen and then remained vigorous without increasing perceptibly for at least a fortnight.

This series may be supplemented by another, and will then serve to shew with what caution inferences must be drawn.

On August 26th certain faint pin-spots on a mature leaf were carefully mapped.

August 30th.—A spore patch appears at the tip of the leaf.

September 2nd.—This is now vigorous and producing spores in numbers.

September 14.—The production of spores far less vigorous.

September 7.—Tip quite brown, as if burnt; hardly any spores at edge of brown patch.

September 3.—The leaf has turned quite yellow; no more spore patches have formed.

October 16th.—The leaf had fallen.

In this example the disease was not established, as evidenced by yellow patches, until the leaf was fully formed (for there were three pairs formed above when the observations began), and even then no spore patch appeared except at the tip; this enjoyed a life of some four or five week and the leaf apparently fell sometime after.

MR. MARSHALL WARD'S ADDRESS ON "COFFEE LEAF-DISEASE."

MR. MARSHALL WARD: You have already had a great deal of your time occupied with very necessary and important business which I, although an outsider, can thoroughly appreciate, and I shall therefore pass as quickly as possible to the subject upon which I have promised to address you. When more than a year ago I came to the island of Ceylon to commence the task upon which I had been engaged to endeavour to fulfil, I saw that that task was a greater one than I had expected when I left England. I am sure you will grant how easy that could be so: that one so far away and with so few opportunities of seeing coffee growing on a large scale could not draw a vivid picture of the amount of material he had to work upon. That was, then my first difficulty, and the second was that I had a tremendous amount of evidence to sift. No one knows better than I do myself and those who worked with me the amount of information which poured in upon me in all manners, modes, and times. I soon saw that although this information was given with the best of intentions, it would not do to accept it in its crude form, but that I must gather information from experience and personal experiments, or else I should find myself in such a whirlpool of unsifted evidence which were not facts, that my work would be ruined, and you would get very little good from my visit to the island. But from the fact of being a human being, I am naturally impressionable, and that evidence would rapidly have led me to adopt a theory which would lead us into a whirlpool of helplessness. Therefore, my duty was to ascertain for myself exactly upon what you based your conclusions. To do this, I mingled with you as much as possible. Of course, so far as the details of planting were concerned, I was a learner, but as willing to learn as any one could be. After a certain amount of experience we rapidly made way, and that led me to publish my first report that should at any rate soon throw some light upon what appeared to be then rather vague. I had in fact to clean the slate and write on it anew: that was a tremendous piece of work. When a few days ago the Secretary of your Association, on behalf of the Committee, asked me to address you, I thought I had better use the opportunity to bring, if possible, before you a few new facts a little supplementary to what has already been published, and to insist upon a few remarks I made public a short time ago—the last time when I had occasion to write, as I heard some of you had either misunderstood, or did not consider, what I laid so much stress upon. Now, to do this, it is necessary that I should bring before you as rapidly and simply as possible the series of facts and the way in which they have been established, as to the enemy you have to fight in leaf-disease. Before doing this we had better explain what we mean by *disease*. Disease may well be explained by the word itself. It is a state of disease in which the organs or parts of the organism do not perform their functions properly. In the particular disease we are speaking of, we deal with the leaves of the trees. The leaves of the tree, for some reason or other, do not perform their functions in a satisfactory manner: they are interfered with in some way. What interferes with them? Some of you had formed your own conclusions before I attempted to form any, and you believe there is something the matter with the tree. This is definite so far as it goes. I take it that leaf-disease is characterized by symptoms as clear as are those of the disease of animals, which I will use for the purpose of illustration. The symptoms you and I sadly enough know very well, but one remarkable point may be insisted upon, and that is the occurrence, in connection with the disease, of a peculiar organism which to the naked eye is as perfect for fulfilment of its purpose as is the coffee tree. It is, in fact, a plant, a fungus. It is the examination of the life history of this fungus, the examination of the work of destruction it causes, and to see how it tides over those awkward breaks in life which occur to all parasites, that is, to see how it reproduces itself; this is the knowledge we require for without this knowledge we have always the possibility of error; and, of course, unseen possibilities are much more numerous than seen facts. Therefore the first step was evidently to try to solve this. I need not weary you with what happened in detail. I would shortly call your attention to the yellow dust you know so well on the leaves. Now it would be invidious to draw comparisons of the examinations of this dust in various parts of the world and by various persons. Suffice it to say, that they are explained by one person in one way and by others in other ways. I have my explanation to give, and you of course, can criticise it. I found that provided certain external conditions were fulfilled—this took me three-quarters of a year to find out—any one of those yellow granules could put forward a delicate tube which might be represented by the little finger. This is studded by warts as if made almost for the purpose, one would think, of sticking to everything it fell upon. I find this body puts forward a small tube which contains all this yellow granular dust. If that occurs on the under side of the coffee leaf and the weather is damp, or rather what in the South of England we call "muggy," this tube grows for a short distance. If it occurs on glass, and there is nothing but water added to these growing pieces of organism, the tube increases slightly, fills with water, bursts, and there is an end of it. If it occurs on rock or stone—as may be seen by actual observation—the same thing happens. But if it occurs on a coffee leaf there are a number of small breathing organs which fulfil several other purposes—the so-called stomata. This tube can make its way into the stomata and the interior of the leaf, just as if it made its way into a small sponge; and there it performs certain tricks. To show that what I state is true, I—for I was very sceptical at first—stripped the skin of a leaf off the living plant very carefully and sowed this body. In 24 hours it grew right into the leaf, and I could see the whole process through the microscope. If you are told there is on the outside of the leaf a *mycelium* of which the branches block up the stomata, and there is a piece of fungus inside the leaf, you are led to infer that there is a connection between them. I did not infer that and if you give me an opportunity I will show it to you. If I were to place upon any one or several of you a series of small leech-like animals—I must say I don't wish to push any analogy between animal and fungus life, but it will illustrate what I mean—suppose on any one of you I placed leeches periodically and withdrew them soon after they had drawn your blood, after a few years or less you would be in a very bad way. How would that come about? Not merely by loss of blood, which would weaken you; not merely by loss of the materials which make the blood, but by the active irritation of the parts occupied by the leeches: the abnormal attempt on the part of the small cells to reproduce themselves, and so get rid of what was annoying them. You would have weakness outside, and if that continued, especially if the organism was a typical one, you would be very ill indeed. Now, gentlemen, without pushing an analogy between the vegetable and animal kingdom, this is practically what occurs in coffee leaf-disease. "If that occurs," you will say, "it is all very well to give an illustration of a leech or flea, but a leech has cutting organs, and a flea has a proboscis," and so on. But strange to relate, but perfectly true, inside the coffee leaf this tissue, for which we use the technical name *mycelium* remains. It sends out a number of branches in all directions, and they send little sucking organs right through the organs of each cell. These sucking organs when quite young are solid. I have given them in detail in my last report. They are quite solid. As they swell and the tube becomes yellow, I see the cell into which it has gone gradually lose its contents, which have their own work to do. This material goes out of the cell into the fungus, and then the fungus, greedy as he is, begins to extend and send branches through a series of stomata, not far, however, from the point at which it entered. Look at the thousands and millions of these. If it were only that removed material there would be a great deal of harm done to the coffee but that is not all. In a complex organ like the coffee plant if you go annoying one cell and take its life like that the other cells will suffer.

There seems, in my mind, quite sufficient justification for asserting that it is an external parasite which is doing the harm. I cannot give you one-tenth part of the results which have led to the conclusion, but there you have an explanation for two facts—a loss of matter to the coffee—a loss of matter in its cells which ought to go to other cells, and irritation of the functions of the cells in their neighbourhood. I will just run over another series of experiments. Suppose that is the leaf of a coffee plant [drawing a leaf on a blackboard], the *mycelium* forms inside and grows out again, but those spores which appear, all appear in a circle round that point entered, or close in the neighbourhood. If you cut a series of sections in this way and examine each, what you will find is this: the section into which the spore first passed has nothing left, the next has something, and the next beyond that has more, and so in "decreasing progression" (if I may use such a term). The yellow patch is what we have to deal with, and is the whole of the business. If you cut into some sections you will find there is part of *Hemileia vastatrix* away from the spores. That is very important. I would have you call to mind the number of leaves on a tree, the material is now before you, the number of those spots you find and the number of spores produced, and I think you will agree with me that if there is not sufficient to explain all the phenomena in the country, I do insist that all the damage done by *Hemileia vastatrix* is done in that way. Now gentlemen, perhaps you say:—"Well, this may be so, but you don't find that parasite develop on cinchona." I question very much, speaking from your point of view, that it would not have appeared on coffee if there had not been something wrong with the coffee. To settle this point I adopted a very simple expedient. I had some seed imported from the West Indies. There is nothing like leaf disease in the West Indies. When I got this seed I got some of the soil which came from a different part of the West Indies. I baked the soil with the earthenware pot which contained it, and subjected it to a red heat. Then I sowed the seed and it came up. Those plants had no trace of leaf-disease about them. I took two or three of those plants and put them in another wardian case and produced the conditions of moisture, heat, &c., that we require for the development of the spores. I then sowed spores on the plants and soon got the leaves diseased just where these spores were sown. Yet another series of experiments. I took the leaves which had been blown about on an estate near, and again was successful; the spots appeared where I sowed the spores. I mention this not to try to impress you, but I want you to see that so far as this evidence goes there is a control over the disease: that is to say, it can be produced. It proceeds in a certain defined cycle and occurs on certain structures, and those structures are the spots on the leaf. I have the material to say a great deal more, but I don't think you will feel inclined to listen to very much. But I should like to bring this to a test: "If this is as you say (again I am placing myself in your position), you ought to be able to show that if you can in any way get rid of leaf-disease you can keep the leaves on the trees." Gentlemen, even in a small measure there should be more leaves on the trees. If you keep more leaves on the trees you should get more crop. In August last year I arranged with a planting gentleman, who I am afraid is not present, but to whom my thanks are due, and I shall thank him in another place, to have 2 acres of coffee, of which I attempted to gain a thorough mastery as to all its conditions. I attempted to enter into the planter's way of looking at it, and I flatter myself that I succeeded. I attempted to make it not only a kind of machine in my hands, but also to enter into the question before us, and I need hardly remind you that I resolved that no part of the experiments should be reported upon except with regard to facts. We have been led to believe that a new idea is almost more than a human being can bear, but a modern philosopher laid great stress upon the fact that it is impossible to account for the evolution of intellect, because it would be more than to account for the pain of a new idea; the worst one is the pain of a revived idea. Revive, please, that painful idea of sulphur and lime. Please don't scoff at me, and bear with me while I say a few words. I had eight acres untouched; I had the rest sulphured and limed according to a well-known recipe. This was in August. I made a few notes. I may mention that it is on this side of Nuwara Eliya. There were 32 acres, about equally good coffee, which had leaf-disease on it in a not very advanced stage. The coffee was about 24 years old. Eight acres below the bungalow were left untouched, 24 acres above the bungalow, on a higher slope, were treated as I said. The difference is slight, but it is important. I went into the past history of this coffee as far as I could, and learned a great deal about it. I found it was impossible to find coffee in such a condition as wanted, viz., two patches manured at the same time. The coffee below the bungalow had been manured two months before that above the bungalow. I need not go into details as to the way in which the experiment was carried on. I have visited that estate a great many times and watched it very carefully. Don't be alarmed; I am not going to recommend sulphur and lime on a large scale. At the end of about two months, the superintendent and I agreed that the upper coffee looked darker than the lower, although we were perfectly certain that the coffee below looked better at the commencement of the experiment. There was a slight difference in the colour of the coffee. During the continuance of the experiment I am perfectly sure many thousands of spores which germinated in the dew of the morning were killed, and other fungoid growths were also killed. There is no secret in this at all. I am not going to cry the praises of sulphur and lime, as you know that sulphurous gas will kill fungoid growths. I am only going to tell you a few facts. I had the crop kept separate at the end of the experiment. I had ten trees on each area selected; I did not select them myself. They were selected so that each tree should be a fair sample of the trees on the patch, and each of them had ten primaries. Each tree's leaves were kept separate and counted. The results two months after the experiment were these:—On ten trees not sulphured there were 13,422 leaves, or 1,342·2 per tree on an average. Their whole weight was [illegible] lbs. On the ten trees which had been sulphured there were 15,822 leaves in all, or 1,582·2 on an average [illegible]. Clearly there were about 200 more leaves per tree on the sulphured area, and if you go into numbers you will find it takes about [illegible] leaves, unsulphured, to the lb., and [illegible] of those which were sulphured. [illegible] other the worst looking coffee at starting and which had been manured

later and was more exposed, &c., put on heavier leaves and more of them. There was more than one cwt. more *pallam* (cherry) per acre on the sulphured area, and the percentage of light coffee was but half as much. I need hardly say I was very much startled, for no one was more sceptical than I was. I am perfectly convinced of the accuracy of these statements I had it repeated a month later. I won't give you the figures, but they bear out practically the result of the first experiment. I may tell you that, at the time of the last experiment, leaf disease had come out again all over the place five or six weeks after the sulphur and lime had been put on. What was I to do? I was much annoyed and perplexed. I think I am justified in accounting for it thus by the tremendous number of leaves which fell off a few days before the sulphur was put on thick with disease and spores, which will do what I said before, provided that they have proper external conditions. If you examine the rainfall for that estate you will see exactly the conditions my experiments demand should be fulfilled to produce leaf-disease when the spores germinated. I consider that it was perfectly demonstrated that the damage was done by the spores of the leaves on the ground. On this account I urge you to pay attention to the fact that you will never get rid of leaf-disease as long as you allow the diseased leaves to remain on the ground as they are now. No specific can be successful so long as you leave the leaves there. (Applause.)

CACOA.

CACOA PLANTS FOR CEYLON.

FROM the Government Botanist, Trinidad, Colonial Secretary.

SIR,—I beg to report for the information of his Excellency the Administrator, and for the notice of the Secretary of State for the Colonies, that I was instructed by his Excellency Sir H. T. Irving in December last, in conformity with the terms of a despatch from the Secretary of State for the Colonies (No. 173 of the 15th November 1879), to prepare a collection of some 240 plants of the best varieties of cocoa for transmission to the Royal Gardens, Kew, thence to be forwarded to Ceylon, Straits Settlements, and Fiji.

2. I now have the satisfaction to announce that the cocoa plants are strong enough to be despatched at once to Ceylon (*viâ* Kew), and that I purpose sending them in five or six Wardian cases by the next mail-packet.

3. I have already, six weeks ago, sent on four representative plants to Kew, to test their condition on arrival there, and am glad to be able to state that they are now sent on to Ceylon in good condition.

4. Some time previous to receiving instructions to prepare these cocoa plants for Ceylon, I had received application for seeds or plants of the tree used commonly here as a shade tree for the cocoa—*Bois immortelle* (or *Erythrina umbrosa*); and some time subsequently a delegate from the Planters' Association in Ceylon, visiting the Islands to obtain information, made special application under the auspices of the Governor of Ceylon for a stock of plants or seeds of the same tree.

5. This tree, or its fellow (*Erythrina velutina*), is indispensable in most localities here, and I imagine it will not be less so in Ceylon when the soil is generally poorer and the wind stronger than here—its function besides that of giving general shade, being to maintain a surface in rich and moist vegetable mould by the deposit and decay of its ample and fleshy leaves.

6. I have to explain that the seeds of this tree are of such a nature that they do not retain their vitality for many days, if exposed, or are not placed under conditions favourable to growth, and therefore there was (indeed still is) some uncertainty that these seeds could be transmitted to Ceylon in a living state. Moreover, these seeds are sparingly produced, and are besides, from various local circumstances, most difficult to obtain, so that I obtained only a few thousands; but in order to make sure of getting a supply of plants to Ceylon this season, I forwarded on 7th March a tin box containing some 700 seeds to the Royal Gardens, Kew, the same to the Royal Botanic Gardens, Ceylon, and a smaller parcel to Mr. Fraser, of Kandanuwara, Ceylon. Those sent for the Botanic Gradens, Ceylon, were addressed to the Governor in view of getting the quickest despatch and delivery. At the time of sending the seeds I wrote full particulars to Mr. Dyer, Assistant Director at Kew, soliciting his co-operation (which he since kindly promised), and explaining that as I felt pretty sure the seeds would reach Kew in a living state, a reserve lot of plants might be raised there for Ceylon should the seeds sent thither fail, and that I would have a stock of plants ready here in the event of the seeds failing at both points.

7. Unfortunately, although I have received several letters from Kew, announcing the arrival of many other plants and seeds, I find no allusion to the arrival of the "shade tree" seeds (at Kew), yet, knowing how keenly they were looked for, I think if they had *not* arrived the circumstance would have been mentioned. I find, however, that those sent to Ceylon have *not* reached, at least so the Director of the Gardens there informed me by letter written the second mail they after were due; meanwhile those sent to Mr. Fraser reached duly!

8. The two parcels addressed for Kew and Ceylon were sent by the usual means to Government-house here for being forwarded in the Governor's bag, and, so far as I can learn, were duly posted. This on the 27th March 1880.

9. It will be seen that my design in sending the seeds was in a sense, experimental, and in view of economy in time and money, for the cost of carriage of the seeds would be less than 1-200th of what that of the plants would be; and I am greatly disappointed that the experiment has not had a decisive issue, as might have been the case had the seeds sent to the Director of the Ceylon Gardens reached duly.

10. Under the uncertainty in respect of the stock of shade trees, I beg to state that I proposed to send on a Wardian case full (40 to 50 plants) by the next mail, in company with the cocoa plants—7th September.

11. I might here mention that any portion of the branch or stem of the shade tree having a bud on it will make a new plant when severed and laid on moist earth—hence the vernacular name "*Bois immortelle*,"—so that with 40 to 50 young plants a large stock might soon be raised by the ordinary process of "cuttings."

12. With regard to the cocoa plants and their variety of kind, I beg to call attention to the fact that the plants are "seedlings," not grafted or "cutting plants." They are therefore liable to variation in respect of their fruit characteristics, i. e., the fruit in some instances will be found to differ from that of the parent trees, and according to which they are named. Indeed from some of the batches I had to weed out the "rogues" or reversions to the original, or at least more ancient and "wild" types called here *Calabacillo* and "Jumbie cocoa," just as nurserymen at home have to do with their batches of seedling fruit plants.

13. This uncertainty of character in the seedling arises of course from the circumstance that in almost every part of the Island many varieties are grown together; the blossoms in consequence receive other pollen or fertilising matter than that of their own tree and the succeeding fruit and progeny are thus hybridized—*i.e.*, they ultimately present characteristics differing more or less from those of the parent trees

14. This process has of course being going on for ages, and as with the selected fruits in Europe the only means for perpetuating with constancy in a great number of individuals, the characterstics of the parent tree is the process of grafting or layering. Such a process, however, in general cultivation would be impracticable at present, and would cost a great deal more than the results would be worth, in the face of abundant "plant" material, in which the majority of the trees are of the good kinds, and have already given a very satisfactory return to the grower, and which majority might be constantly increased by saving *for planting seeds only of the best kinds*.

15. The best kinds are by no means well known however. Indeed, with the majority of *growers* here they are not known at all, and they never notice a difference in the character of the trees nor that of the sample or produce—except in respect of the *Calabacillo* or "wild" cocoa, and this they very rarely eliminate. In the whole range of varities, however, there is a difference in the value of yield of at least one to five.

16. Under these circumstances, the value of the cocoa plants now forwarded should be regarded as of rather a botanical or scientific nature than as agricultural or economic one for immediate effect; for the varieties being separated and described as far as it is practical to have them, there is a base for experiments and test as to what are their real characters and what may be done with them in the way of improvement.

17. The issue cannot be obtained however for *five years* at least, and therefore the plants will not be available for planting stock, for a longer time than that in the Colonies to which it is designed to send them.

18. The demand for seeds and plants of the finer Trinidad varieties of cocoa is already so great as to make the matter of supply suggest the character of a commercial enterprise, particularly in respect of Ceylon. So long ago as 1877 the Kew report instances Trinidad cocoa being sent to Ceylon, and since then thousands of plants and pods of seeds have been sent from private sources as well as from the gardens here, the majority being of course of the finer sorts, so that in all probability in Ceylon as here, satisfied with the degree of *excellence* of the mass, the colonists will proceed to plant without regard to distinction of the kinds employed, as they find they are able to obtain plants for the purpose.

19. Moreover, it seems certain that some of the best varieties of cocoa are already in Ceylon, the trees bearing and their produce sold in London at 10*os.* per cwt. A sample of this was brought under my notice last year by a cocoa planter here who, from his good judgment and industry improved his estate and sold it at an advance of 50 per cent. in three years. Trinidad "finest" cocoa at the time sold at 120*s* per cwt. and the opinion of this gentleman was that had the Ceylon sample come from Trinidad, it would have fetched the Trinidad price, so good and well prepared was it. It was with its brand *new in the market*, and therefore was not sought after

20. With such evidence of so good a kind of cocoa being already in Ceylon, and available for propagation, taken together with the circumstance that any considerable stock of plants could be transmitted from this Colony to Fiji, Singapore, &c., only at great expense and delay, I am led to suggest that effort be made to meet the apparently increasing requirements of these places with cocoa plants *raised in Ceylon* for, as I have endeavoured to shew, the variety of cocoa already in Ceylon seems to be of a higher and more valuable class than is supposed by the Ceylon people themselves

21. In the event of any cocoa plants being sent to Fiji, from whatever point, I would beg specially to mention, as applicants of long standing, Mr. Stephens of Levuka, Fiji, and Mrs. Kington, Plantation Cove, Fiji, both having applied to me many months since, but who, without some intermediary assistance, I am unable to aid.

22. In conclusion, I would venture to express a hope that there will be no objection to the information concerning cocoa and its cultivation herein given, being communicated to the officers at the Royal Gardens, Kew, who are very desirous to receive such information, and which, not having yet been able to complete a treatise on this subject I have long had in hand, I am desirous to communicate to them on every occasion for doing so that presents itself.

I have, &c.,
HY. PRESTON,
Government Botanist,
St. Ann's, Trinidad,
4th September 1880.

SOMETHING ABOUT CHOCOLATE.

THE complaints put forward in some journals of the adulteration to which all kinds of preparations of cocoa and chocolate are subjected, are exceedingly out of place, so much so indeed that we will undertake to say that very few persons would care to drink a preparation of the cacoa bean in its natural state without any extraneous aid. If this should be insisted upon, then we should have to condemn the whole chocolate industry of Paris, whose delicious preparations find a welcome in almost every corner of the world

Perhaps the nearest approach to the pure cocoa nut are the preparations known as Schweitzer cocotina and Epps' Homœapathic cocoa, but they although admirable suited for invalids or persons of weak digestion, are not such general favorites as the other products of the nut. We may remark by the way that the sample of Ceylon prepared chocolate powder, exhibited by the grower and preparer of the article at the last Agricultural Show in Columbo, was in like manner not absolutely pure, having been blended very skillfully and delicately with sugar and a little arrow root.

In Paris the manufacture is carried on upon a most extensive scale, as indeed is the case in London with this difference that the French article is far superior in quality to the English. This is accounted for by the fact that the Parisian makers use none but beans of the very finest quality, and bestow more pains in the preparation. They employ an infinity of foreign ingredients in the manufacture and greatly to the improvement of their goods.

Our readers are probably aware that one of the main flavouring ingredients, if not the chief, is vanilla, the produce of Mauritius, Bourbon, and a few other places. Very recently we gave some figures shewing the extent of which the demand for this valuable and delicate flavouring

material had grown in proof of this and as showing to what a degree of excellence everything connected with the chocolate manufacture is carried, we may refer to one of the most recent inventions in the preparation of flavouring materials. A London firm had recently introduced an article into the trade which they term concentrate vanilla sugar which is a perfect substitute for the natural vanilla bean, combining the exquisite aroma and flavour for which bean is held in such high repute, in an admirable manner. The high price of ordinary vanilla has been sufficient to preclude its general adoption and a cheaper substitute, such as the vanilla presents, will no doubt attract considerable patronage from the public in general. Vanilla sugar in addition to its being more economical has the virtue of being most easily manipulated, and for use as a flavouring agent in blanc-manges, puddings, creams, custards, ices, &c., will, doubtless eventually supersede natural vanilla.

The basis of vanilla sugar is pure vanilla crystals which we are told are now being manufactured on a large scale, and consist of the same substance (synthetically produced) as "the papillæ of the natural bean" which alone gives aroma to the latter. The strength of these crystals is estimated to be forty to fifty times stronger than that of the natural vanilla. They dissolve very quickly either in alcohol (in the proportion of one part of vanilline in five of alcohol), or in warm syrup, and when mixed with sugar, or dissolve in alcohol or syrups will be found a most advantageous substitute for the troublesome and more expensive vanilla beans, which, as is well known are liable to mouldiness and decomposition, and to very so much in quality.

Neither vanilla crystals nor their different preprations ever ferment or deteriorate in quality, and keep any length of time without undergoing any alteration. Probably all this exquisite flavouring principle employed by the chocolate-makers will be regarded as so much of adulteration by some writers, in ignorance of what constitutes the most popular form of this delicate article of dietary.—*Ceylon Times*

CINCHONA.

THE Batavia *Dagblad* draws attention to the fact that the Government Java cinchona bark brings in the European market an estimated average price of 2*s.* 6*d.* per English lb., while Jamaica cinchona bark brings an average of 3*s.* 9*d.* per lb.

THE cinchona crop in Java last year for exportation amounted to fully 100,000, Amsterdam pounds.

DURING the last official year the Government Cinchona plantations in British Sikkim produced 8.164 bs of febrifuge at a cost of Rs 10-2 per lb. Of this quantity 2,757lbs. were sold to the public, and the remainder was disposed of to the Medical Departments of the three presidencies. The drug is steadily rising in general estimation, as is shown by the fact that the sales to the public last year exceeded those of 1878-79 by 358lbs. The total expenditure on the cinchona plantations from the commencement, including compound interests at 4 per cent., has been less than ten lakhs of rupees, while the revenue for the year amounted to Rs. 1,36,773, which is a profit of a little over $5\frac{1}{2}$ per cent. on the capital. This, however, does not represent the whole profit on the year's operations, for the stock in hand has been increased in value by Rs. 42,775, which is equivalent to another 4 per cent on the capital. During the year the amount of febrifuge used in Government hospitals and dispensaries as a substitute for quinine was 5,400lbs., and taking the average price of sulphate of quinine at Rs. 90, the saving effected during the year would appear to amount to nearly four lakhs of rupees, and the total saving since the factory commenced operations has aggregated over eleven lakhs of rupees; actually more than the cost of the plantations. This is a result on which the Government is to be heartily congratulated.

THE number of cinchona plants distributed by Mr. E. J. Thwaites since the year 1868, from the Hakgalla gardens, Ceylon, was as follows:—From 1868 up to 1872, *plants not charged for*, supplied to planters, also to Police Stations, Government Rest-houses, and villages in (Uva).

Not charged for	...	...	504.000
Sold 1873	...	...	458 000
" 1874	...	...	778.900
" 1875	...	...	779.200
" 1876	...	...	1,224.000
" 1877	...	...	698 000
" 1878	...	...	164 000
" 1879	...	...	38 095
" 1880	...	...	52,260
Total	...	...	4,696,455

Most of the above plants were raised from cuttings.

CARTHAGENA CINCHONA PLANTS.

THE following is a letter from Mr. A. Jamieson, Superintendent of the Government Botanical Gardens, Ootacamund, to Mr. N. A. Roupell, Acting Commissioner, Ootacamund, dated 11th January 1881:—With reference to your official memorandum, No. 254, of the 14th ultimo, I have the honor to report that five of the six hard carthagena bark plants brought to Ootacamund by Mr. Cross (four of these were young succulent plants) damped off during the wet sunless weather of November last. I was, however, able to save a portion of the plants for cuttings, and have succeeded in propagating four healthy young plants from the cuttings. The sixth plant is in excellent condition and will yield a dozen or more cuttings in the course of a few weeks. Our stock at present consists of five healthy plants and five unrooted cuttings; these cuttings will be rooted and fit to transplant into pots by the end of this month, so that by the first or second week in February the stock of carthagena bark plants should consist of ten established plants and a number of cuttings. The above results would, I have no doubt, been more satisfactory had I been able to give the plants more close personal attention, but unfortunately I was, through severe illness, confined to bed for three weeks when the plants were at the most critical stage and the weather not at all favorable to the growth of plants that required a warmer climate than that of Ootacamund. I have, however, not the least doubt that by the middle of July next the stock of this cinchona will have been increased to fifty or eighty plants. The plant of *erythroxylon coca* is thoroughly established, and has yielded several cuttings.

CINCHONA BARK AND ITS FEBRIFUGE ALKALOIDS.

THE roots, flowers, and capsules of the cinchona tree have a bitter taste with tonic properties, but the upper bark is the only part which is commercially valuable. M. Delondre decided that the fruit and flowers, though having a bitter principle, do not contain the alkaloids, while the roots contain them, though in a smaller proportion than the bark of the trunk and branches. The bark is composed of four layers—the epiderm, the periderm the cellular layer, and the liber or fibrous layer, composed of hexagonal cells filled with resinous matter and woody tissue.

In growing, the tree pushes out the bark, and as the exterior part ceases to grow, it separates into layers, and forms the dead part or periderm; which in cinchona is partially destroyed, and blended with the thallus of lichens.

The bark is thus formed of the dead part, or periderm, and the living part or derm.

On young branches there is no dead part, the exterior layers remaining entire while the inner layers have not had time to develope. In thick old branches, on the contrary, the periderm or dead part is considerable, while the fibrous layer of the derm is fully developed. In preparing the bark the periderm is removed by striking the trunk with a mallet, and the derm is then taken off by uniform incisions.

The character of the transverse fracture affords an important criterion of the bark.

Cellular tissue breaks with a short and smooth fracture, woody tissue with a fibrous fracture, as in the case with *Calisaya* bark. The best characteristics by which barks containing much quinine may be distinguished, are the shortness of the fibres which cover the transverse fracture and the facility with which they may be detached, instead, of being flexible and adhering as in barks. Thus, when dry *Calisaya* bark is handled, a quantity of little prickles run into the skin, and this forms one of its distinguishing marks.

Until the present century Peruvian bark was used in its crude state, and numerous attempts were made at different times to discover the actual healing principal in the bark before success was finally attained. The first trial which is worthy of attention was made in 1779 by the chemists Buguet and Cornette, who recognised the existence of an essential salt, a resinous and an earthy matter in quinquina bark.

In 1790 Fourcroy discovered the existence of a colouring matter, afterwards called cinchona red and a Swedish doctor named Westring, 1800, believed that he had discovered the active principle in quinquina bark. In 1802 the French chemist Armand Seguin undertook the bark trade on a large scale, and found it necessary to steady the means of discovering good barks, and distinguishing them from bad ones. He found that the best quinquina bark was precipitated by annin, while the bad was not precipitated by the substance. In 1803 another chemist found a crystalline substance in the bark which he called "self-essential febrifuge," but it is nothing more than the combination of lime with an acid which was named quinine acid. Reuss, a Russian chemist, 1815 was the first to give a tolerable analysis of quinquina bark, and about the same time Dr. Duncan of Edinburgh suggested that a real substance existed as a febrifuge principle.

Dr. Gomes, a Surgeon in the Portuguese Navy, in 1816, was the first to isolate this febrifuge principle hinted at by Dr. Duncan, and he called it cinchonia.

But the final discovery of quinine is due to the French chemists Pelletier and Caventou, in 1820. They considered that a vegetable alkaloid, analogous to morphine and strychnine, existed in quinquina bark, and they afterwards discovered that the febrifuge principle was seated in two alkaloids, separate or together, in the different kinds of bark, called quinine and cinchona with the same virtues, which, however, were much more powerful in quinine. It was believed that in most barks cinchonine existed in the cellular layer, and quinine in the liber, or fibrous layer; but Mr. Howard had since shown that this view is quite incorrect. In 1829 Pelletier discovered a third alkaloid, which he called aricine, of no use in medicine, and derived from a worthless species of cinchona growing in most of the forests of Pegu, called *C. pubescens*.

The organic constituents of cinchona barks are:—

Quina	Quinine acid
Cinchona	Cinchona red
Aricina	A yellow colouring matter
Quinidia	A green fatty matter
Cinchonidia	Starch
Quinine acid	Gum
Tannic acid	Liquid

These materials are in different proportions according to the barks. Grey barks chiefly contain cinchonine and tannin; *Calisaya*, or yellow bark, much quinine, and a little cinchonine; red bark holds a large precentage of cinchonine, while the barks of Columbia chiefly contains quinine, cinchonidine and quinidine. The two latter alkaloids were difficultly discovered on 1852 by M. Pasteur, although the Dutch chemist Heijningen had, in 1848, found what he called quinine or quinidine. Quinine is a white substance, without smell, bitter, fusible, crystallised, with the property of left-handed rotatory polarisation (laevogyrate). The salts of quinine are soluble in water, alcohol, and ether. Of all the salts the bisulphate of quinine is preferred, because it constitutes a stable salt, easy to prepare and containing a strong proportion of alkaloid. It is very bitter and soluble, and crystallises in long silky needles. It is prepared by adding sulphuric acid to the sulphate. Cinchonine differs from quinine in being less soluble in water and being altoget er insoluble in ether. It has the property of right-handed rotatory polarisation (destrogyrate). Quinidine also has the property of right-handed rotatory polarisation, and forms salts like those of quinine. It becomes green by successive additions of chloride and ammonia. Cinchonidine has not the sulphate of turning green and forms a sulphate almost exactly like sulphate of quinine (laevogyrate.)

The discovery of the alkaloids in the quinquina bark, by enabling chemists to extract the healing principle, has greatly increased the usefulness of the drug.

Cinchonidine and quinidine are quite equal to quinine as cures for fever, and cinchloridine is only slightly less efficacious. It is equally a febrifuge, but must be taken in larger doses. Thus these alkaloids not only possess tonic properties to which recourse may be had under a multitude of circumstances, but also have febrifuge virtue which is unequalled, and which has rendered them almost a necessary of life in tropical countries and in low marshy situations where agues prevail. Many a poor fellow's life was saved in the Walcheren expedition by the timely arrival of a Yankee trader with some chests of bark, after the supply had entirely failed in the camp.

Dr. Baikie, in the voyage up the Niger; attributed the return of his men alive to the habitual use of quinine. And the number of men whose lives it has saved in our naval service and India will give a notion of the vast importance of a sufficient and cheap supply of the precious bark which yields it. India and other countries have been vainly searched for a substitute for quinine, and we may say with as much truth now as Lambert did in 1820.

"This medicine, the most precious of all those known in the art of healing, is one of the greatest conquests made by man over the vegetable kingdom. The treasure which Peru yields, and which the Spaniards sought and dug out of the bowels of the earth, are not to be compared for utility with the bark of the quinquina tree, which they for a long time ignored—MARKHAM.

SERICULTURE.

USEFUL MEMORANDA.

THE following are a few interesting figures which may prove useful to silk growers:—

Weight of Cocoons.—This varies with the breed and feeding. Pasteur calculates that 1 kilogramme contains 785 to 92. cocoons of the Japanese sort; 505 to 72. cocoons of the Italian yellow sort. Comalia found that 860 cocoons of the Meidola sort weigh 1 kilogramme.

Loss of Weight in Cocoons.—This is caused by time of keeping. Dandola found that at a temperature of 17 deg. R. 1·000 kilos. of cocoons was reduced to—

Kilos ...	·991	·982	·975	·970	·966	·960	·952
Number of days	1	2	3	4	5	6	7
	·943	·934	·925				
	8	9	10				

Weight of the various parts of Cocoons.—By taking at 1,000 the weight of the whole cocoon—

The chrysalis alive weighs	from	...	830 to 850
The refuse of chrysalis	,,	...	4 to 9
The clean cocoon ,,	,,	...	140 to 166

After the moth has left the cocoon in 1,000 parts of them—

Refuse of moth	...	...	...	5 to 6
Remains of chrysalis	...	...	...	7 to 9
Clean pure cocoon	...	...	...	140 to 163

Number of Eggs.—Malpighi has found that the number of eggs deposited at one laying is generally 504 or 516, and sometimes only 416. As an exception he met once with only 393 without taking into account any which may have remained in the ovaries.

According to Barti-Pichet, 100 females deposit at one laying 40,000 to 45,000 eggs, and 108 females of the Trivoltine sort are required for one ounce of eggs; 100 females of the common sort, 95 of the large, and 105 to 110 of the Japanese.

Number of Eggs in an Ounce.—1 ounce of 30 grammes of eggs was found to contain—

27,000 eggs of the Trivoltine breed.
39,000 ,, common ,,
37,000 ,, large ,,

1 ounce of 25 grammes of eggs was found to contain—

38,500 to 37,000 of the yellow breed.
45,000 to 51,900 ,, Japanese breed.

Eggs which are deposited from the first are little larger than those from the second average number in one ounce, 45,000 eggs.

Weight of each Lay of Eggs.—To find out this without removing the eggs from the cloth or cards, the basis of the calculation is to take the weight of each separate laying. It is known that to obtain the weight of two grammes it requires—

5 lays of the large French breed.
6 ,, common ,,
7 ,, Japanese ,,

From this we can conclude that to make up 25 grammes there is required—

68 lays of the first sort.
70 ,, second ,,
75 ,, third ,,

To make up one ounce of 28 grammes, 70, 84, 90, respectively; to make up one ounce of 30 grammes, 75, 9 , 1 5, respectively.

SILKWORM RAISING IN RUSSIA.—In 1850 the Government of Ekaterinoslaw produced 857 chetwerts of cocoons; (the chetwert is equal to 2 0 litres); that of Tauride 4,768; that of Kherson 128; and the different districts of Bessarabia 1,549—total, 6,·02 chetwerts. The sale produced 153 pounds of 40 pounds each, at a price of from 3 to 4 roubles per pound, yielding nearly £3,000. This was an increase of 49 pounds on the produce of the previous year.

Among the Russian peasantry, however, little progress is made in sericulture. In the Crimea the Nogais Tartars alone have endeavoured to follow the example of the German colonists in giving attention to this subject.

Since 1858, when this industry attained its climax, silk rearing has gradually declined. For instance, the produce of the districts of Bakmoustska, which in 1858 was 200 pounds, fell in 1874 to less than 4 pounds. In consequence the Southern Society of Odessa has abandoned further efforts in this direction.—*Journal of Applied Science.*

WILD SILKS OF INDIA.

MR. S. C. LISTER, the head of the firm of Messrs. Lister & Co., of the Manningham Mills, near Bradford, is about to visit India for the purpose of making investigations relative to the wild silks of that country. He thinks the wild silks of India have an important future before them, but that it will take time to develope them. In a letter of December 4th, he writes:—"Eria and Muga are far before tassar, but any of them can be used profitably when the conditions of profitable success are duly considered. Usually, tassar as when reeled by the natives, is so full of faults as to be dear at any price, and when reeled by Europeans so costly as not to pay. The problem to solve is how to produce it cheaply and yet fit to use, and that is what I am aiming at. As to Eria, it is simply a question of cost of production in the first place, and then can it be reeled? if not, can it be produced so cheap as to pay to use it for combing and spinning?" He writes further:—"I feel no manner of doubt that with time and patience wild silk will be profitably used."

THE JAPAN SILK-WORM EGG TRADE.

WE regret to observe that the Agricultural Bureau seriously contemplates an export of silk-worm eggs from the farms in Yeso. That this pernicious trade should receive official sanction, is not only lamentable but inexplicable. The Japanese have not hitherto given the world any just cause to accuse them of utter commercial ineptitude, but in this matter they are assuredly laying the seeds of such a reputation. Their own language contains two very opposite aphorisms; one describing the rat that gnawed away the base of the pillar in which he lived, and the other telling of a rustic simpleton who sold bait for coppers to those that desired to angle in his pond, instead of catching the fish himself and exchanging them for broad gold pieces. The silk-worm egg farmers would probably be a good deal offended if we used either of these fables to illustrate their conduct, but as a matter of fact the similes would err, not on the side of caricature, but of flattery, for whereas the rat and the rustic were the only sufferers by their own folly, every merchant in Japan will presently have cause to lament the fatuity of the egg exporters.

Indeed, like some of the very elementary truths in mathematics, the thing is so self-evident that one can scarcely command patience to demonstrate it. Surely we need not point out that this trade is at once self-destructive, and fatal to the vital interests of the whole silk manufacture. Self-destructive, because every card that finds its way westward, permanently supplies a portion of the Continental growers' wants; fatal to the silk manufacture, because the result must ultimately be a transfer of the producing power from Japan to Europe.

Official interference in such matters is, as a rule, to be deprecated, but here is a case so obviously detrimental to the country's commercial welfare, that we should heartily welcome any prohibitive action on the part of the authorities. If, however, the Agricultural Bureau is not maligned, we can only bow our heads and say 'Quos Deus vult perdere, prius dementat.'

While writing on the subject of silk-worm eggs, we take the opportunity of correcting a false impression that seems to have been conveyed by a passage in our opening article for this year. In detailing the commercial events of 1880, we confine ourselves as far as possible to the history of the period, and did not therefore refer to conditions whose origin dates back more than a decade. When we described certain operations in the silk-worm export trade, nothing was farther from our thoughts than a desire to recommend the trade as beneficial. Indeed it is scarcely fair, we submit, to draw such an inference from our statement, since nobody approves of smuggling or larceny, though all will admit that considerable profits have been realized by contraband whiskey and swallowed diamonds. Zeal is however sometime disposed to be indiscriminate, and with our contemporary's honest warmth, in such a cause we can most heartily sympathize:—*Japan Weekly Mail.*

The suggestions and inquiries which during his visit to Lucknow in the winter of 1879, Sir George Couper made respecting agriculture in Oudh, have at last borne fruit says the Lahore paper, and the opening of the Lucknow Exhibition may mark a new era in the agricultural history of the province.

The deliberations of the landlords' parliament at Lucknow are conducted in the language of the country, and will subsequently be printed and distributed for the information of the farmer class, and the collection of opinions. Again, in questions of agricultural improvement, as a rule, Governments have not only taken the lead, but they have generally conducted their experiment on their own sole responsibility. In this case, Government is merely a sharer in the enterprise. Only two Englishmen are members of the Committee of Management, the Honorary Secretary (Major Noble) and the Director of the Agricultural Department; the other ten are natives. We need hardly say that the questions under discussion—irrigation, fodders, and manures, selection of seeds, improved ploughs, the extension of arboriculture—are of the utmost importance to the people of Oudh. It is true that the Oudh talookdars have begun with a condemnation of certain systems of irrigation, and it is quite possible that they may have done so from selfish reasons. But it is equally possible that something may be said for the adoption of well-irrigation in preference to canal-irrigation, at least in some localities. In any case, it is a great advantage—as well a rare occurrence—to have heard the candid opinion of natives on an important matter; and the discussion must produce some good.

TOBACCO.

THE tobacco industry of Pusa seems to be making good progress the report of operations for 1879-80 being now to hand.

The outturn of 1879-80 crop is not given, but we are informed that that of 1878 79, was 120,000lbs. against an estimate of 165,000, a deficiency of 27 per cent. This added to their previous stock enabled them to turn out 163,000lbs. of cured tobacco. During the 20 month ending with November 1880, the sales of cake and cut tobacco totalled Rs. 1,17,565, which is satisfactory, as showing that a market exists for it, notwithstanding the firm hold which American cake and English mixtures have on the public taste.

More recently, the manufacture of cigars has been gone into, and the sales are daily increasing, having amounted to Rs. 750 per month, towards the close of 1880. The operations at Pusa and Ghazeepore being now carried on by a private firm, details of cost are not given, but enough is said to warrant the inference that a good business can be done.

Few can be ignorant that a brisk trade in tobacco is carried on by us with the Malabar coast. The tobacco is generally sent up by sailing vessels between October and April. During the south-west monsoon steamers take it, and the quantity very seldom falls short of 6,000 candies. We have already exported 6,000 candies and 5,000 more will be sent before April next. In all something like 100,000 candies will be sent this year instead of 6,000 as usual. It however appears that the trade is not so profitable now as some time back. The price has gone down there and a candy which was before sold at Rs. 300, now sells only 240, from which must be deducted the Customs duty. There is then Rs. 110 which is hardly sufficient to pay the original value of the article in Jaffna.

TOBACCO CULTURE IN SUMATRA.

THE following interesting account of tobacco planting enterprise and prospects in Deli, on the east coast of Sumatra, is sent by a Mr. Tolson to the *Ceylon Observer*. After giving a brief physical outline of the country Mr Tolson describe the manner and form in which grants of land are obtained by intending planters, and he proceeds:—

Having once obtained a contract confirmed in due form, our first object is to get the jungle cut for a sufficient number of coolies and their fields. This we do by contract with the natives, chiefly Battaks, at the rate of $30 per 100 depahs or fathoms square, which is tantamount to $31 per 5 bouws or $6 per bouw, and a temporary shanty is in no time put up for us, though of course it would be pleasanter if we were able to put up with a near neighbour, until a proper house is built. Such a house, standing on posts, having a roof of attap or mana grass, possessing four bedrooms a dining-room and front and back verandah, all on the first floor, with an office and some godowns on the ground floor, costs us Rs 1,500. We began with 75 men, but I think this a mistake, and consider, that provided you are sure of the suitability of your soil, 150 men would answer far better as your first outlay in a dwelling house, a fermenting shed which costs Rs. 2,500 and tobacco-press costing Rs. 1,500 laid down here, is no greater with 150 fields or men than with half that number. The extra expense would chiefly consist of more drying sheds, which cost Rs. 700 each and are meant to serve two years.

September is the proper month to commence cutting jungle in, and in a couple of months or so a quantity of forest should be felled to allow of your arranging for 150 fields, which are generally ten depahs along the road by 150 depahs deep. The roads and drains are as a rule made by Tamils, or Klings, as we call them, but as these are scarce, and, owing to prohibitive emigration rules extant in Penang and British India, difficult to get, it is advisable to engage your coolies, Chinese, in the autumn, and set them to work at the roads, &c., on monthly wages, say, at $6, until January, when it is usual to put them in the fields under Tandils, who have 30 to 40 men each assigned them, and get them to staple the twigs, small wood and rubbish in heaps, burn same, clean and chunkul or dig the fields so as to be ready to receive and plant out the young seedlings in April. Each field will hold about 10,000 plants and in the case of an extra good cooly, when he has got through the allotted work in good time, more land and plants are given him, so that one hears of some of the fellows delivering as many as 1,500 to 1,100 plants. The planting lasts between 60 and 90 days, all depending on a plentiful supply of light showery weather or otherwise. Rain is essential for the very young plants, and often an unfortunate cooly, deceived by one or two light showers, has seen the young seedlings killed off by a week's succeeding drought, and has had to commence his work *de novo*. When once he is in the field he works on his own account, getting merely a monthly advance of about $1, and he is credited with the tobacco plants he brings into the drying sheds or *Bangsals* at the rate $1 to $3 per thousand plants, according to the length and quality of the leaf, although he gets no settlement of his account until the last of the sorting has been done. The plants take, generally speaking, a month to dry: the leaves are then made into bundles, and carried to the fermenting shed, where they are stapled in staples which go on increasing till they reach 10 to left high, and left to ferment. These staples require frequent turning over, and care is required to give the whole parcel an equal degree of heat, and not too little of it, the process of fermenting lasting about three months. The next is to sort the tobacco into shades and colours, of which the number vary on the different estates, but in baling only some ten varieties are in general use, while prior to the last process the leaves are sorted into lengths numbered 1 to 4. For assisting at this work, and indeed for everything the Chinese cooly does, over and above his planting and field works, he gets paid daily wages which amount to about $3 monthly. When, therefore, towards the end of the year, or when you are late with your crop, early in January you square up with your men, you find that your good and experienced ones have not only worked off the monthly advance of $4, besides that which they received on engaging with you, generally $30, their passage money, &c. scores, the cost of the medicine supplied them during the year, say $1 each, the $5 cost of cutting the heavy jungle of their fields with which you debit them, the cost of tools (unless returned), and the 2,000 trade-tax the Government exacts, which amounts to $3, but have a balance standing to their credit of $100 and more, although I acknowledge this is quite an exception for them to make in their first year, most of the steady workers having then realised only some $2 to $13, while the majority, through bad luck and inexperience, have been unable to square their advances and still show a debit balance in their accounts, which, however, they rub off the year following. Besides the above-mentioned $30 a man advanced to the cooly, the planter is forced to pay the broker or go-between in Penang a commission of from $ 0 to $12 a man, which he has simply to write off to charges account, and cannot claim from the cooly.

The tobacco, when baled in bales weighing about 1½ cwt., is put into boats or rather large dug-outs, and sent down by river to the port of shipment, and there (Rantoh-Pangang always excepted) put into receiving hulks, whence it is taken by steamer to Penang for transhipment either to Amsterdam direct or *vià* London. Insurance we pay is 3 per cent, which covers all fire risk, while in the drying and fermenting sheds, and all river and sea risk to Penang, besides risks of landing and reshipping and risk while stored in Penang, and further sea risk to Amsterdam. There is an export duty hence of one guilder per 80 kilos, equivalent to 0 per cent. *ad valorem*.

Cost of production is, roughly speaking, $40 a picul, without charges of shipment, &c., provided a planter works not on too small a scale, and has not too many casualties among his coolies, for you can readily fancy the difference it makes on the cost of your crop if you have to write off the debts of 5 to 10 deceased coolies, or of 30 to 40; while the average value of the tobacco in the Amsterdam market is $80 per picul, though of course some crops fetch considerably higher prices. Even the above rate leaves a fair margin of profit accruing yearly, and, seeing that it is a profit, it is not to be wondered that planters not overburdened with spare capital should prefer adhering to a culture which at best is but a transient one, rather than to devote themselves to other and more permanent produce, which would necessitate the locking-up of capital for so many years, besides absorbing a number of costly coolies, who would be as profitably, if not more so, employed in the tobacco fields.

I should not omit giving you the following figures, to show you the progress of this place, and the stride made in tobacco cultivation since its first year of starting, namely, 1865, when 189 bales of 1½ cwt. each were shipped. In 1870 the amount had increased to 3,114 bales; in 1875 to 15,147 bales; and this year the export will fall little short of 60,000 bales, representing a value of close on one million sterling. Last year, the crop of 1878 was realised at an average rate of 131 guilder cents per half kilo for Deli, 126 guilder cents for Langkat, and 107 cents for Sirdang kinds, or say 2s. per lb., 1s. 11*d*. per lb. and 1s. 7½*d*. per lb. respectively.

We publish the following papers at this Office :—

THE INDIAN AGRICULTURIST.

A MONTHLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY AND STATISTICS.

VOL. VI.] CALCUTTA :—MONDAY, 2ND MAY 1881. [No. 5.

NOTICE.

The INDIAN AGRICULTURIST *will be supplied to all Schools and Missionaries in India at half price.*

CONTENTS:

NOTICE TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

CORRESPONDENCE.

WEEDS ON COFFEE AND TEA ESTATES.

TO THE EDITOR.

SIR,—In your foot-note of NOVICE'S letter, you don't point out whether you are referring to manured land or not: and if you mean any kind of land, I beg to differ with you in that respect, I have had several years' experience planting in the hills, and I find the best kind of cultivation is, to let the jungle grow a considerable height (by no means let it seed) and then if the heavy rains are on, cut it down with the sickle and hoe it in afterwards, and my opinion is hoeing the ground too often does it more harm than good, not only does this jungle enrich the soil when it is hoed in, but it protects it through the rains from being washed away in the plains, I believe land cannot be hoed too often in the rains, because the jungle grows so strong, even if hill gardens are kept manured, hoeing them all through the rains you will find the soil deteriorate considerably,

GARDENER.

It can never be advantageous to allow weeds to grow, instead of valuing the benefit which weeds hoed in does the ground, would it not be better to induce the food plant which formed those weeds to go to the plant at first hand?—ED., *I. A.*

ABOUT PAPER FIBRES.

TO THE EDITOR.

SIR,—In my last letter I stated "that in point of fact the paper-maker if he could procure them in sufficient abundance, and at reasonable cost, would infinitely prefer 'rags' to any other material."

In making this broad assertion, an assertion I must admit somewhat at variance with my long continued efforts to induce attention to the introduction of fresh supplies of *raw fibrous material* suitable for paper-making—some explanation is required.

Although as I have stated "rags" would be preferred to any other material, practically speaking a sufficient supply can only with difficulty be procured to meet the requirements of the makers of the higher grades of paper, who consequently with but few exceptions are compelled to employ with them as an admixture so called *raw fibrous material*; the bulk of the paper now manufactured in this and other countries really containing a comparatively very small portion of "rags," *raw fibrous material* such as *Esparto* grass, wood pulp, straw, &c., &c., entering largely into the composition of the medium and lower classes of white papers.

The classification of "rags" is very wide indeed; ranging in cost from £6 up to £36 and even £40 per ton. In addition to "rags", (technically so called) but classified with them in the market or trade, we have cotton waste, flax, and hemp, tow or waste, jute waste, jute ends or butts, gunny bagging, hemp, manilla, and other rope, &c., &c.

Now the fabrics from which "rags" (technically so called) results have been originally composed of yarns, spun from the finely divided fibres of cotton, flax, hemp, and jute, the latter having since the Crimean war been largely introduced (from India) and either mixed with, or substituted for, flax and cotton, in the manufacture of so-called "cloth" especially in the class termed "domestics" *i. e.*, household linen.

All cloth fabrics from which paper-making "rags" are derived, are of vegetable origin, and in addition to the ordinary mechanical processes of scutching, heckling, spinning into yarn, and the weaving of such yarn into a web in the loom, have been more or less subjected to various chemical processes, during which they have been deprived of a considerable quantity (by weight) of the gummo-resinous, coloring and other extraneous substances, constituting a portion of the normal *corpus* or substance of all vegetable fibres.

In addition to this also, before the fabric or cloth really becomes a "rag," during its use as an article of clothing or otherwise, it has been subjected to the manipulations of the wash-tub, or to disintegration by the friction of ordinary wear-and-tear; rags, especially those of low grades are generally very foul and dirty, arising from the grease and other impurities contracted during their use as fabrics, this being readily discharged by washing, after saponification by boiling in lime or weak alkali, previous to bleaching and conversion into the "stock," half-stuff, or pulp of the paper-maker.

Hempen and other rope, flax and jute waste gunny, bagging, &c., &c., may really be regarded as "raw fibres," except that unlike "raw fibres" *ordinarily so called* they all have more or less undergone a partial process of retting previous to a mechanical treatment of sub-division, it may be well to add that ordinary "raw fibrous materials" (so called) are not, and cannot be technically termed "fibres," until or before they have been really reduced to a fibrous condition.

If any one of your readers will take up a sheet of good writing paper for instance, and hold it up before him in a strong light, he will not be able to see any appearance of fibre therein; it presents a creamy homogenous structure not unlike parchment or vellum, and again if he will tear off a strip and look at the edge of the strip so torn, he will remark the filamentous or fibrous tissue forming the structure, or *corpus* of the sheet, indeed it is not until the rag or other fibre has passed through the complicated chemical and mechanical processes of the paper-maker, that it has become sufficiently broken up or comminuted, to admit of its felting or interlacing so as to form a firm, smooth sheet of paper.

The foregoing remarks illustrating the treatment which rags, and rag material have undergone *previous* to coming into the hands of the paper-maker, will demonstrate how much their ultimate treatment for his use has been facilitated, thus fully justifying his preference and it follows that the more nearly any "new fibrous material" or fibre, either by reason of its original structure, or normal composition, or by mechanical or chemical processes of treatment, can be made to assimilate to "rag material" (so called), the more readily it will meet the requirements of the paper-maker, and therefore more readily find a market.

THOS. ROUTLEDGE.

Claxheugh, Sunderland, March 1881.

WELL IRRIGATION.

TO THE EDITOR.

SIR,—In your issue of the 1st April last, is published a reprint of a letter on the subject of "Well Irrigation in Guzerat" from the *Times of India*, in which the writer makes some very sensible and pertinent remarks. The subject of well irrigation is one which might not only engage the attention of Government, but also of all those who are desirous of advancing "improved agriculture." While the natives of India have several modes of lifting water from wells, the principal in those parts being the *jinkottah* worked by manual labor and the *kuppalay* worked by bullock, it has struck me as curious that no attempt has been made, at least I have not seen nor am I aware of any experiments being tried—to introduce the windmill, by means of which a great deal of labor might be saved and a powerful agent utilised. For the greater part of the year, and principally during the dry hot months, when irrigation for crops is necessary, there is always a steady wind blowing, and if a cheap pump could be devised, instead of the bullock power, why not attempt to have it worked by a mill. Bullocks will have to be replaced, get worn out or may die, but a mill once put up would not need much expense to keep it in working order, and would require nothing in the shape of fodder.

I would commend this matter to the attention of the eminent engineering firms which advertise in your valuable journal, such as Burn & Co., of Calcutta, Owens & Co., England; if they could hit the point off, it would bring them in large orders. I have not seen the plan of Major Steel's, R.E., pump, it was said I think that this gentleman had patented an improved water lift in the N.-W. P., but I would ask, could it not be worked by a windmill. There is also an improved water lift brought into use in the Government Farm at Cawnpore, this I think could be made to work by the mill attachment. Again I believe that some of the watering stations on the G. I. P. R. have windmills to work pumps for filling the water tanks: could not Government depute some officer to report upon their working. Though these pumps may be elaborate or costly, yet it is quite possible to modify the whole to such an extent as to bring out what is wanted, *viz.*, a cheap and simple pump or water lift worked by wind.

T. T. L.

Bangalore, April 8, 1881.

THE RIVAL PLOUGHS.

(To the Editor of the Express.)

AS the description given by your reporter of my plough is misleading, allow me to state that the one he refers to as having the mould-board and share in one sheet, was exhibited merely as a specimen of a *cheap* plough, the price being only Rs. 2, which will not admit of any elaboration in the construction of the share, the same description of plough is made by me with separate steel shares, which are easily renewable, for Rs. 3-8 each. The efficiency of the plough was fully demonstrated at the trial, and the taluqdars and gentlemen interested in the contest were unanimous in their expressions of approval, so favourable was the impression made by it.

The ploughs, wholely made of iron, are made with special reference to the requirements for the ryot, and I claim that they meet the wants of the Kasthkar in their present condition as nearly in every particular as it is possible to do so within the limits of their means. The ploughman has nothing new to learn to use the plough, the draught is not greater than that of a large size native plough, while a furrow averaging 5"×7" can be made and the sod completely turned over, bringing to the surface the sub-soil and exposing it to the fructifying influence of the sun and rain, a desideratum hitherto unattained save by powerful American and English ploughs, which are utterly unsuited for the cattle and the people of the country. The share is made of steel capable of being "drawn" or renewable easily, and the stilt so arranged as to give the highest effect and leave one hand of the ploughman free to drive and guide the bullocks at will. In point of efficiency and durability the plough, I venture to say will be most popular for general work; and Rs. 7 for such an implement I consider quite within the reach of all well-to-do Assamis. At the trials my ploughs maintained a high position throughout, and I was informed by very good authority that, had the price been Re. 1 lower, I should have won the first prize in the contest.

With regard to the position of the stilt, to which your reporter takes particular exception, I beg to state the angle adopted was arrived at after repeated trials, conducted *personally*, as the one most suitable, and had the author of the report consulted me on the subject, I should have been able to give him convincing proofs of this.

With regard to Mr. Martin's plough, permit me to inform you that the model is *mine*; and in the specification I filed in January 1879, I described that the stilt may be of any suitable form, and I was greatly surprised to find Mr. Martin claiming the plough as an original production, when I am informed he obtained the pattern from the Government Model Farm here, and during my absence in England brought it out as his *own invention*! When questioned by me, he based his claim to originality *solely* on the position of the stilt, as compared with the one I exhibited. Had your reporter examined the ploughs, he would have experienced no difficulty in recognising the parent of Mr. Martin's plough in the two rupee specimen exhibited by me. In justice to myself, I think it is due that the facts stated should be made public, and I trust you will be kind enough to give this letter a corner in your journal.

Cawnpore; 19th March 1881.

Yours faithfully,

GAVIN JONES.

THE EFFECT OF TREE-CLEARING ON RAINFALL.

(To the Editor of the Melbourne Argus.)

SIR,—Recently several instances have been brought under notice of the increased discharge of some streams in Australia owing to the destruction of trees on part of the ground drained by those streams. Some years ago, when I was giving evidence before the Water-supply Board, of which the late Mr. A. K. Smith was a member, that gentleman, when examining me, stated that in Tasmania the clearance of trees along a creek, had augmented the flow of that creek and he then asked me whether such fact would not modify my strongly expressed opinion that the destruction of trees on the Mount Disappointment ranges would lessen the rainfall thereon, and consequently reduce the supply of water to the Yan Yean reservoir. My reply to Mr. Smith's question was that such fact would not make me alter my opinion. Quite recently a very intelligent and trustworthy officer of the Lands Department, Mr. Callanan, has given instances in which the clearance of trees near some creeks has augmented their discharge; and I have been informed that the destruction of a dense growth of trees on a dry flat caused the surface of that flat to become a swamp.

Before showing that these instances are not inconsistent with the fact universally recognised by scientists and practical foresters, that

ceteris paribus, a heavily wooded tract of forest land attracts more rainfall than an unwooded tract, I may state that those tracts of country in Victoria which display arboreal vegetation of unusual magnitude, density, and luxuriance, and which consequently receive an exceptionally great rainfall, have a rich porous soil of very great depth. Ages ago arboreal vegetation must have commenced to grow in such soil more vigorously and luxuriantly than in ordinary soil, which vegetation attracted rain, whereby in the course of ages the special luxuriance of such vegetation became more and more developed, owing to the increased moisture; and the present result is that in some parts of Victoria there is, on soil of the description alluded to, arboreal vegetation unsurpassed with regard to size, density, and luxuriance in any part of the globe, and growing under the influence of a rainfall enormously great, when compared with the ordinary rate of rainfall in Victoria. Whilst the altitude of ranges of mountains in Victoria has great influence on the amount of rainfall thereon, such influence is less than that of the arboreal vegetation thereon. Meteorological observations in Victoria show that at stations of comparatively low elevation on ranges covered with lofty *eucalyptus* growing close together amidst light wood, fern trees, musk, hazel, &c., the annual rate of rainfall has been very much greater than at stations of greater elevation on high ranges of ordinary thinly-wooded forest. I may refer, as an example, to the tract of ranges and gullies between the eastern fall of the Dandenong range and the granitic range at Beenac. The average elevation of such tract above the sea is not more than 900ft., and a large portion of the tract displays rich, very deep, porous soil, derived from feldspar prophyry; it is densely wooded by very large *eucalyptus amigdalina*, *eucalyptus sieberiana eucalyptus goniocalyx*, and *eucalyptus obliqua*, growing amidst subordinate groves of acacia *melanoxylon*, *alsophylia*, and Dicksonia fern trees, musk, &c. From observations it has been found that on this tract the annual rainfall is exceedingly great, a rain-gauge at one station having shown a rate of rainfall for 1880 three times as great as the recorded rate of rainfall at Melbourne for that year. Large trees of *eucalyptus* exhale a great quantity of water, consequently, if in such a tract as that described such trees be destroyed within the watershed of any creek, on a portion of ground of so small an area as to be of almost inappreciable extent when compared with the general area of the tract, the quantity of water that was conveyed by the trees from the soil into the atmosphere would, after the destruction of the trees, tend to increase the flow of the creek, whilst, owing to the very limited area of the surface deprived of trees when compared with the area covered by arboreal vegetation, the rain clouds attracted by that vegetation would not have their general discharge over the whole of the tract arrested when passing over the very insignificant portion of such tract deprived of trees. In the tract of country to which I have alluded, I noticed that the ringing of trees on about 100 acres of land at the head of a gully had increased the flow of water in a spring at that head, obviously owing to the cause just stated, and which is also the cause of the increased flow in the creeks mentioned by the late Mr. A. K. Smith and Mr. Callanan.

Wherever the tract of country to which I have alluded, or any similar heavily and densely wooded tracts become generally denuded of trees, the present exceptionally great rainfall thereon will no longer prevail.—Yours, &c.,

February 23. CLEMENT HODGKINSON.

ARTESIAN WELLS.

(To the Editor of the Australasian.)

SIR,—Mr. Richard Bennett, in his letter to *The Australasian* of 5th March, claims the credit of being the first, in the year 1872, to publicly advocate the adoption of artesian wells. In 1858 the late Mr. B. A. Cunningham spent nearly £1,000 in trying to strike artesian water on his estate near Sale, and much was written about it in the Gipps Land Press at that time. In 1870 it was publicly proposed to bore for artesian water at Sale; in the autumn of 1880 boring for an artesian well was proceeded with by the Borough Council, and this time with brilliant success. Mr. Bennett mentions that artesian water has been obtained on the Darling by a bore which, with a 4in. pipe, gives 17,000 gallons of water in 24 hours, rising to the height of 4ft. above the surface of the ground. At Sale, the artesian water flows through a pipe only 2in. in diameter, yet it gives 46,000 gallons a day, or nearly three times as much, through a pipe only half the size of the one used on the Darling! The water at Sale rises to the unprecedented height of 43ft. above the surface.

Mr. Bennett complains that his scientific friends have taken him to task for his theories. He says that the pressure of the atmosphere on the level plains will force the water up from the caverns below! This is unscientific, indeed! It is the pressure of the atmosphere that ordinarily prevents water from rising. An artesian well may be possible even when no mountains are near, but it cannot exist unless a water-bearing stratum be tapped which has its source in a reservoir of water stored at a level higher than the surface of the ground at the site of the well.

The value of the property of the selector, the farmer, and the grazier would be enormously increased in value by the possession of a stream flowing high above the surface. I firmly believe that artesian water can be found in very many places in this colony, and often in positions undreamt of by the cultivators of the soil and the dwellers in dry places. That eminent prelate, the Bishop of Melbourne struck a true keynote when he suggested that irrigation would shower down blessings on Victoria. Taking encouragement from the splendid result achieved at Sale, let us go on in our efforts to promote irrigation by means of artesian water. Our farmers will then have a powerful friend which will bring them prosperity; and if in time sounder fiscal principles prevail, and legalised robbery of the farmers by taxing all they use be abolished—for these taxes, worse than "borrowing, blunt the edge of husbandry"—then this country "will be a fine country for the working man!"—a term which should include every honest man and exclude only the greedy, trading politicians, who are at present bleeding the body politic to exhaustion and syncope.—Yours, &c.,

PUITS ARTESIEN

THOSE PLOUGHS AGAIN!

(To the Editor of the Express.)

SIR,—The *Pioneer's* "Own," in giving an account of the agricultural show recently held at this station, has the following in reference to ploughs exhibited on this occasion:—"Among the implements were several kinds of adopted ploughs exhibited by Mr. Martin, Mr. Crawley, Mr. Gavin Jones, and the Department of Agriculture, which also brought forward an adapted winnower which should in time obtain a ready sale. An essay might be written on the comparative merits of the native and the adapted English ploughs, and of deep and shallow ploughing, but a stricter test and more searching examination is required than has been possible before any decided opinion can be arrived at." The *Pioneer's* "Own" has been guilty of both *suppressio veri* and *suggestio falsi* in the version he has given in the passage just quoted, as the public will see from the unvarnished statement of facts given below. A committee had been appointed to subject the ploughs exhibited on the occasion, to a strict test and searching examination. It was composed of some of the most enlightened and independent Talukdars and native officials of the district, who, from their experience and personal knowledge of agriculture could speak with authority on the subject; and who were thoroughly disinterested and unbiassed. The following is an accurate translation of the Report of the committee:—

"Extract from the Report of the Committee which sat at Bulandshahr on the 25th of February 1881, to award prizes to exhibitors of agricultural implements.

PRESENT:

Rajah Luchman Sing,—Deputy Collector—President.

MEMBERS.

Peerji Mohabut Ali, of Kadree Bagh.
Kunwar Faiz Ali Khan, Taluqdar of Pahasu.
Ghoolam Haidur Khan, Taluqdar of Chundrow.
Syed Abdul Kasim Khan, Taluqdar of Kumarsi.
Kunwar Beni Krishna, Taluqdar, of Sikunderabad.
Khusiram, Raiess of Bhutowanal.
Mr. Crawley, of the Agricultural Department.

The following agricultural implements were exhibited at the show:—

Hindustani ploughs.	9
English do.	2
Combined English and Hindustani	6

In judging of the merits of the above implements, and awarding prizes, the following points were taken into consideration by the Committee:—

1st. Simplicity of construction.
2nd. Lightness.
3rd. Cheapness.
4th. Depth of furrow.
5th. Turning over the sod and rooting out grass.

A plot of ground was separately ploughed by the various implements exhibited to test their capacities and merits on the points mentioned above. The Hindustani ploughs were found totally deficient on the 5th point, and the English ploughs on the first three points; whilst the combined or adapted ploughs possessed all these advantages more or less. Of this class the Committee consider Mr. Martin's plough to be best, as it possesses all the fine qualities mentioned above in the highest degree. The next in order of merit is Mr. Crawley's plough, and the

third is the one made by the Department of Agriculture and Commerce; and prizes are awarded accordingly. The committee find that the plough exhibited by the Department of Agriculture is unsuited to the habits and wants of cultivators in this country, inasmuch as it is pulled by a rope instead of a pole; and until the driver has acquired sufficient experience and proficiency in working it, the furrows it makes are sometimes straight, sometimes crooked, sometimes deep, and sometimes shallow. The Hindustani ploughs have no particular merit, but "as Peerjee's is the best of those exhibited, it is awarded a prize."

The report of the committee speaks for itself, and any comments on it would be superfluous. How in the face of these facts the *Pioneer's* "own" did not hesitate to suggest that the ploughs exhibited at the Bulandshahr show were not subjected to a strict test and searching examination, is more than I can pretend to understand. The committee very wisely decided not to award any prize to the English ploughs exhibited at the show. I do not know what kinds of English ploughs were exhibited; but I find from an advertisement of Messrs. T. E. Thomson & Co., of Calcutta, that the lightest and cheapest English plough—namely that which is known as Howard's patent iron dwarf plough, with one wheel marked D—weighs 1¼cwt. and costs Rs 45 each. Both the weight and cost of this implement make its introduction into this country an utter impossibility.

It may be asked why the plough to which the first prize was awarded this year at the Bulandshahr show, had so signally failed last year at the same place. I am not in a position to explain this fully. I find from your impression of the 16th March that Mr. Martin's plough was exhibited at Lucknow, and that the exhibitor afterwards withdrew his implement from competition. The *Pioneer's* "Own," with characteristic fairness, mentioned the fact of the withdrawal, but did not state why the plough was withdrawn. Mr. Martin had very good reasons for adopting the course he followed. The plough sub-committee of Lucknow declined to consider the question of draught, which is the most important point for consideration. You rightly think that Mr. Martin's plough was the best of those exhibited at Lucknow, and your opinion is supported by experts like the Editor of the *Indian Agriculturist*. Mr. Martin's plough was tried in some places in Bengal with other adapted ploughs, and some English ones, and pronounced a success, as you will have seen from the Calcutta papers. As the Department of Agriculture has failed to beat it down by its own invention, or by the inventions of others in which it takes a deep interest, it is time that the department should cast aside all feeling of jealousy, and recognize that Mr. Martin's plough is the best and most successful of all the implements of this kind yet invented and patented in this country. It is also time that the Government should take steps to make Martin's invention widely known among the agricultural classes who are ignorant and unlettered, and whom advertisements in newspapers cannot reach. The price of Mr. Martin's plough is so low, only Rs. 4, that it is within the means of the poorest ryot.

FAIRPLAY.

Bulandshahar, April 23, 1881.

OSTRICH FARMING.

(To the Editor of the Argus.)

SIR,—In your issue of the 1st instant is an extract from a letter of Mr. J D. Ellis to the *South Australian Register*, giving a short account of the beginning and progress of ostrich farming in the Cape Colony, and offering the opinion apparently in ignorance of what has already been done here, that "ostriches would flourish exceedingly well in Australia." With your permission, and for the information of those of your readers who take an interest in this matter, it may not be out of place to say that ostrich farming has been established for some years, if not in Victoria at least in the neighbouring colony of New South Wales, in close proximity to our own borders.

About the year 1866, through the efforts of the Acclimatisation Society of Victoria and its then President, Dr. Thos. Black, who is justly entitled to the honour of being considered the founder of this new Australian industry, several ostriches were imported from South Africa. The climate of Melbourne, however, proved to be unsuitable for them, and in May 1868, they were sent to Longerenong Station on the Wimmera, the property of Mr. (now Sir) Samuel Wilson. Here they remained until February 1874, when, at the suggestion of Dr. Black, as they had neither increased in numbers nor thriven as they were expected to do, it was decided to remove them further north to the Murray Downs Station, on the New South Wales side of the Murray River, and close to the Victorian township, Swan-hill. Of 11 kinds that were started from the Wimmera, six only arrived at their destination, five having died, either from the effects of injuries received in securing them at Longerenong, or from the confinement and hardship sustained on the long land journey.

At Murray Downs the industry has been continued to the present time under the personal superintendence of Mr. S. H. Officer, one of the proprietors of the station. The amount of success year by year has been variable, owing to difficulties inseparable from a new undertaking, but there are now in all some 56 birds, and, with one or two exceptions, these are in a healthy, thriving condition. The feathers are sold in the London market, and the prices realised compare very favourably with those obtained from the best products from domesticated birds of South Africa.

An adult returns about £10 worth annually. They are kept in closely paled paddocks, over which they roam, and pick whatever suitable herbage they can find. In addition, however, they are provided with an abundance of lucerne, maize, or mangolds, all grown under a system of irrigation. Crushed bones and quartz in considerable quantities have to be added; the former to supply the phosphate of lime necessary for, the production of good feathers, and the latter as an aid to digestion. So far the expenses of the farm have largely exceeded the profits, but it may be confidently expected that the balance will soon be on the other side of the ledger.—Yours, &c.,

C. O. M.

Feb. 15.

COFFEE.

(To the Editor of the Madras Mail.)

SIR,—As I am about to invest in coffee, I should be much obliged if any practical coffee planter would kindly give me through the medium of your columns, the results of his experience on the following little points.

Often, in walking over estates of two hundred acres and upwards, you will observe single trees and little patches of coffee here and there, bearing at the rate of ten cwts per acre, and in the case of the single trees often as high as at the rate of four tons per acre. On inquiry you will find that the average crop of the whole estate is under thirty tons. The expenditure you will be told is about two thousand pounds per annum and with a shrewd guess you will know that your friend is receiving some five hundred pounds a year as interest on the money sunk in his estate, and considers himself rather a lucky man and worth (by his own valuation) some ten thousand pounds—the value of his two hundred acres of coffee. He will blandly tell you that coffee property is cheap at fifty pounds per acre. I am told that this would be a good estate. On the other hand you will often see gardens of an acre or so in extent, about bungalows in towns where manure is easily got, bearing annually at the rate of one ton per acre. Now what I want to know is whether I should buy a large estate, or whether I should buy fifty or sixty acres of the best jungle procurable, and having opened it out, begin with heavy manuring from say the second year of its growth. By heavy manuring I mean sufficient to force it to give at least ten cwts per acre. As single trees on a large estate, without manure, will give ten cwts per acre, I presume that by manuring sixty acres sufficiently heavily at least thirty tons could be produced annually, and at a much cheaper price than it could be on an estate of two hundred acres, and of course with a great deal more profit. About manure not being procurable in sufficient quantity for the above system of cultivation, I am told that any quantity of bone dust and Poonac meal can always be got on the Western Coast, and furthermore that these manures if only on account of their easiness of application, are cheaper in the end than cattle manure is.

CALCUTTA [illegible].

CINCHONA SEED.

(To the Editor of the Ceylon Times.)

SIR,—I think it my duty to mention a circumstance which took my attention recently in connection with cinchona seed. I observed a good number of cinchonas evidently between three and four years of age dying off with ripened seed on them. These seeds were being collected by coolies, and I am aware that the manager is at the present time disposing of cinchona seed to a number of persons who are no doubt in ignorance of the fact that they have been gathered from dying trees. Even should the seed in question germinate, the plants raised cannot become healthy trees, and my object in writing you is to enter a protest against this sale of bad seed. May not this account for very many of the early failures of young cinchonas quite as much as careless planting and bad soil.

COFFEE.

The Indian Agriculturist.

CALCUTTA, MAY 2, 1881.

PROSPECTS OF THE PRESENT TEA SEASON.

THE present is one of those periods in the tea season, at which we feel compelled to pause and take a careful look, both retrospective and prospective, and from which we should, after having carefully studied the position, take a fresh departure.

On this occasion we propose only taking up one subject—that of prices. There are doubtless other subjects which might be discussed with much advantage, but this is perhaps the most important to the shareholder. This latter unfortunate individual has had a bad time of it for several years past, and it is high time that he saw a break in the clouds. Let us therefore see whether the past and present condition of the market will warrant us in giving him any hope. We shall first look at *production*. For many years past, an insane mania for extension has existed, and the amount of damage this has done to the industry is incalculable. The drawbacks to indiscriminate extension of area are many, but we shall only observe two, the effects on the garden and on the market.

The effect in the garden has been to involve concerns in financial difficulties, which in turn re-acted in the produce and in the general condition of the garden. Money has been for a long time a scarce commodity, and gardens were worked to the verge of insolvency. Under such circumstances it was useless to look for a good outturn, either as to quantity or quality. In consideration of the extra sum spent in these extensions, shareholders were anxiously looking for returns, and to provide something in this way, managers and managing agents were forced to their wits' ends. The practical result was a lot of tea produced under high pressure, made with insufficient means, and often with

insufficient labour. Averages fell low, and every one was disappointed. In the present state of the industry we would recommend no extension, but would strongly urge a continuous effort towards making existing gardens thoroughly efficient. After a few years this success will doubtless be obtained, and then the time for extension will have arrived. After the garden is found to be in thoroughly good condition, we would recommend easy extensions *from revenue*. The capital account of most concerns is too high, and by a steady extension of cultivation from revenue, this capital would gradually be brought within bounds. We would recommend these extensions to be gradually carried out, till the capital value of each acre stood at a maximum of rupees four hundred, while we should prefer three hundred. Then we would also point out with regard to a property being thoroughly successful, that that point may generally be assumed to have been attained, when the garden produces 400lbs. of tea per acre, at a *maximum* cost of eight annas per pound, including all charges till sale, the tea to be of such a quality that it shall realize a *minimum* of twelve annas per lb., all round. We should then have a clear profit of four annas per pound, or one hundred rupees per acre per annum, which, allowing for contingencies, would admit of a dividend at the rate of twenty per cent. These figures are general, and do not of course apply in exceptional cases. Then as to the effect of those extensions on the market. We find from all sides that the good name of Indian tea is kept down, because of the large quantities of low class teas which are now made. A recent report from London, says: "The low broken proportion is considerably "in excess of the demand, and as much of it is below the average "quality, even of this class of tea, prices have further declined," and further on: "The competition for the finest teas shows no "abatement, and the few fine brands brought forward, have "fetched extreme prices."

Here then we have in a nut shell, one great cause of the low prices, we are flooding the market with rubbish, made in obedience to the demand of managing agents and shareholders for quantity. It is very easy to make quantity if quality is almost ignored. That they can both be had is quite possible, but is a question of increased outlay.

The most recent statistics at our disposal, bring the state of the London market down to the end of February, and as from the 1st July 1880 to the end of February includes the bulk of the crop, we may form an opinion from the figures presented to us. Here then are the imports for the past few years :—

		lbs.	per centage over 1875-76.
1875-76	...	... 20,357,000	...
1876-77	...	... 22,832,200	12
1877-78	...	... 29,796,800	46
1878-79	...	... 28,127,000	38
1879-80	...	... 32,906,600	62
1880-81	...	... 37,950,600	86

Thus we find that London received Indian teas in steadily increasing quantity. The imports for the eight months ending 28 February 1881, were 86 per cent. higher than for the corresponding period of 1875-76, or, at the rate of say 17 per cent. per annum on the average.

Now let us see what consumption was, during that same period :—

		lbs.	percentage over 1875-76
1875-76	...	... 16,891,000	...
1876-77	...	... 17,334,000	3
1877-78	..	... 21,232,500	26
1878-79	...	... 23,831,800	41
1879-80	...	... 23,176,700	37
1880-81	...	... 30,653,800	81

It will be seen at once that the increase of consumption relatively to production, was less than it should have been, hence fair or remunerative prices were impossible. During the last year however, consumption took a rapid stride to the front. The following table gives at a glance the relative increases of imports and deliveries over 1875-76 calculated at per cent.

		Imports	Deliveries.
1876-77	...	... 12	3
1877-78	...	... 46	26
1878-79	...	... 38	41
1879-80	...	... 62	37
1880-81	...	... 86	81

Deliveries are now heavier than imports, and as a natural consequence prices must rise. They may not for a few months, because stocks are still abnormally high. The cause of this increased consumption is worthy of being looked into, because if it is brought about by the exceedingly low prices ruling recently, it is not a healthy sign, and may cease when prices approach a higher point. We hold, however, that while this may have influenced the increase to a small extent, the cause of the improved deliveries is to be found in a growing taste for Indian Teas. This is a healthy sign, and one which should inspire shareholders with hope. In round numbers imports at present amount to about 3¾ million pounds per month, while consumption demands about 4½ million pounds. The difference between these two quantities being equal to seven million pounds per annum. And this increase in deliveries is not a transient affair of a couple of months, but has lasted for the past nine months.

Now that the taste for Indian tea is advancing at home, it behoves planters to make an effort to encourage it by producing a good tea, and by a determined effort not to flood the market with cheap low class teas. A glance at any London brokers' report, tells us that there is much room for improvement in this respect. There we find large breaks of tea having realised an average rate of 9¾*d.* and 10*d.* per lb. which is discreditable to all concerned. That these could have consisted of low class teas is negatived by the fact that the breaks are too large. For instance, we find 238 chests, average 9¾*d.*; 167 chest; average 10*d.*; 206 chests, average 10½*d.*; 1,294 chests, average 11½*d.*, and so on. We next find broken teas selling at from 5¼*d.* to 2*s.*, 7¾*d.* per lb. Pekoe Souchongs from 1*s.*, 4¾*d.* to 3*s.* 0½*d.* per lb., showing wide inequalities, and, in the case of those whose teas are selling at very low rates, ample room for improvement. Let all extensions be stopped, and let our attention be occupied in improving the land we have under crop at present. This accomplished, will lead to steady improvement in every department of the industry.

LIBERIAN COFFEE.

MR. D. MORRIS of Coffee Leaf-disease fame, and presently Director of Public Gardens and Plantations, has kindly sent us a copy of his recent report on Liberian Coffee. We propose condensing the more practical parts of the report for the benefit of our readers :—

This variety derives its specific name from the Republic of Liberia on the west coast of Africa. This little State lies about 7½ degrees north of the equator, and exactly in the same latitude as Ceylon. This particular class of coffee, seems to occupy the same position in regard to coffee, that the indigenous variety of tea does to tea generally. It is not a bush but tree, and is frequently met with twenty feet in height. Its botanical name is *Coffea Liberica*, and it produces berries of a large size than do the *Coffea Arabica* and *Coffea Bengalensis*.

The following information regarding its cultivation in Liberia will not be without interest to planters.

The coast of Liberia is described as "low but rising towards the interior; well watered with numerous streams; the soil rich, and producing in abundance coffee (Liberian), sugar and all other tropical articles." Another account mentions, "that the climate is hot and oppressive during the dry season, lasting from May to November, with an average temperature of 85° Fahr. This falls in the wet season to 74° or 75°. The heat is alleviated by the sea breezes which blow daily from the sea. The rainfall is much the same as that in Sierra Leone, which has 189·69 inches per annum.' This excessive rainfall is no doubt made up of very heavy downpours, "tornados," during a few months in the year more especially as the dry season is said to last seven months—from May to November. An experienced Ceylon planter who visited Liberia with the object of becoming thoroughly acquainted with its Coffee and the conditions under which it flourished, speaks of the coffee as being grown "quite close to the sea, and forming magnificent trees" "and the soil as evidently volcanic." "The soil of the hills of Musardo being composed of a reddish clay and sand, with boulders of iron ore intermixed; in the north-easern side of the town are some large masses of black and grey granite." Another Ceylon planter who visited Liberia in 1876 failed to see "any great superiority in the Liberian soil as compared with Ceylon," observing

"that ironstone was everywhere present." The climate he described as "wet, stewy, and forcing."

A resident speaking of the "lay of land" most suitable, says, that "level ground suits best, provided there be no risk of an accumulation of stagnant water during heavy rains." Experience has taught us the same lesson regarding tea. Hilly steep land soon loses its strength, by heavy rains washing away the *humus*. On the other hand, on level gland, this is retained, and plants keep their pristine vigour, always provided that water does not lie.

The following is the result of experience among the local Negro planters:—

"The trees on a plantation differ in the size of their berries. Besides, while many contain berries of a uniform size, others will contain berries of various sizes. We are not prepared to say to what extent high cultivation would remedy this. In planting nurseries with the seed of a uniform size, we have not been able to obtain plants of a uniform size.

The coffee does not produce well under shade, either in the quantity or quality of the crop. When the trees are not large enough to shade the gronnd with their branches and fallen leaves, they should be mulched in the dry season; that is, their roots should be covered with dried grass, straw, shavings, or anything capable of shading them, but the leaves and branches should have the influence of the sun to elaborate a due proportion of sap into fruit buds. The Liberian Coffee being indigenous when well established, does not suffer from our tropical sun. Mulching in the dry season is generally required for very young trees on dry hilly slopes.

The trees grow to a height of twenty feet or more; we have seen one more than thirty feet in height. this was in the woods near an old plantation. Some cultivators top their trees, others let them grow up *ad libitum*. Our trees are topped at a height of five feet. trees that are topped are more conveniently picked, and other, Things being equal give a larger crop; when the trees grow up tall moreover, they are frequently injured by climbing with ladders, and pulling down the limbs, &c., and as the tree ripens its crop and blossoms for the next year, at the same time, much of the blossoms and young fruit if rubbed off the trees; whereas the low trees are picked by standing on the ground.

Manuring is not done extensively, owing principally to the fact that most of the plantations are young, although there are some that need manure. We use the Coffee pulp mixed with cattle manure, also decomposed vegetable matter, wood, ashes, the "compost heap" the earth from the hill made by the white ants (termites), &c. The coffee tree delights in nitrogenous manures. We find surface manuring best for the coffee tree here, as the fibrous roots or feeders keep always near the surface.

We have no very old plantations but we believe the plantations can be kept up permanently, or at least for a great number of years. With us the coffee plant is not a shrub; it is a forest tree. There are trees here forty years old, flourishing in all the vigour and verdure of youth, and bending down under their weight of berries. We have seen a few old trees, when cut down, shoot up more rapidly and more vigorously than when first planted from the seed."

"As may be supposed from the habit and size of the trees, the berries of Liberian Coffee are generally larger and finer than those of the ordinary Coffee. The average length of the berry of *C. Arabica*, seldom exceeds ½ in., while the average length of the berry of *C. Liberica* is nearly ¾ in. The pulp or outer covering of the Liberian Coffee berries is thick, rather fibrous, and more or less fleshy, but never succulent as in the ordinary coffee. The shell just under the pulp, the parchment or "indurated endocarp" is of a dull brown colour. The "silver skin" which comes next is strong and tough, dipping into the deep furrow in the face of the seed, and carefully investing the substance of the coffee bean. In descriptive notes on Liberian Coffee, berries and seeds, it may not be out of place to describe their character and structure with some detail, and placed before those interested in the subject facts, which may prove of some value in dealing with the propagation and distribution of this promising plant. The seeds of Liberian Coffee enclosed within their investing coats are generally two in number when one seed as is sometimes the case, becomes abortive, the other seed receiving all the nourishment of the berry, becomes large and rounded, and is termed a "pea bean." When the pulp is removed, the seed covered by the hard brittle shell (the indurated endocarp) is technically termed a "pyrene;" there are therefore two "pyrenes" in each perfect berry. The pyrene is convex on the back, flat, with a narrow, usually deep, longitudinal furrow on the face. If the hard shell investing the pyrene, the "parchment" be removed, we expose what is generally called "rice coffee," carefully examined the structures which make up the rice coffee or *seeds*, are resolved into a membraneous testa or coat of the seed, the "silver skin;" a horny folded mass termed the albumen; and embedded in the substance of the latter near its base is a small body called the embryo, the miniature Liberian Coffee tree, not more than one third inch in full length.

The comparative value of the coffee berries of this plant and of the ordinary variety, tells very most in favour of the Liberian. As a general rule it may be said to be worth fifteen per cent. more than the other, and when to this is added the other characteristic connected with, it, *viz.*, its greater productiveness, it may well be looked on as a great improvement on the *Coffea Arabica*:—

From the concluding remark of this interesting report we take the following.

The information given in the last two sections as regards the yield of Liberian Coffee trees, and the commercial value of the produce will doubtless lead to the conclusion that this coffee possesses characteristics, which according to the circumstances of a country may be utilized to an extent now unthought of. In the first place, the fact that this coffee will grow on the plains, where the preliminary expenses in the acquisition and clearing of land are naturally much lower than on the hills; where labour is cheaper, and where the difficulties and expences of transport would be avoided, gives Liberian Coffee an advantage, not only over its congener the Arabian Coffee, but also over almost any cultivation requiring the same capital and attention. In many of the rich vales of Jamaica, cacao can be very successfully and remuneratively grown, and in conjunction with Liberian Coffee, there is a vast field of enterprise open for it in many parts of the Island, but, it must be remembered that the demand for cacao is much less extensive than for coffee,* and the fact that the American market is so favourable to the large-beaned and prolific coffee, gives its cultivation the aspect of a thoroughly sound investment. The robust and hardy character of the [illegible] is a point that is much dwelt upon in Ceylon, and though it actually possesses no immunity from the deadly coffee leaf-disease, it is nevertheless able to bear its effects much more successfully, than *C. Arabica*, and on this account alone it deserves careful attention in all coffee-growing countries. Though fortunately the coffee leaf-disease, is as yet confined to the Eastern coffee areas, it is the opinion of an eminent authority that the coffee areas of the New World may not ultimately escape its ravages, and it is therefore both wise and prudent to give due attention to the cultivation of a plant which may in some measure, check or modify its action.† With regard to the West Indian blight so deadly an enemy to coffee cultivation in Dominica, the other Windward islands and Brazil the Liberian Coffee appears to withstand its effects with comparative impunity. The President of Dominica writing in 1877 remarks:—"The native coffee is still suffering from blight...... The Liberian Coffee trees although in close proximity to the native coffee, seem to bid defiance to the ravages of this scourge, while the luxuriance of its foliage causes a painful contrast. Writing in 1878, Dr. Imray remarks that "while some of the very young seedlings were affected by blight he was able to report that his trees of Liberian Coffee still remained free from the attacks of that dire scourge of the coffee plant in this part of the world—the Cemiostoma Coffeellum.

* Coffee may be said to form almost the exclusive dietetic warm beverage of 100,000,000 of the human race, and the value of the world's production of coffee (over 14 millions cwts.), is estimated at more than £50,000,000 in the Wholesale Market.

† The effects of the coffee leaf-disease upon coffee cultivation in Ceylon may be very distinctly traced. "In 1869-70 before the disease had appeared, Ceylon exported 1,009,206 cwts of coffee. In 1876-77 when there were 62,000 more acres in bearing, the total exports were only 797,768 cwts." The influence of the disease has also seriously reduced the yield per acre. "Previous to and including 1871, the average yield for five years over the whole Island had been 4·5 cwts. per acre, whilst for the five succeeding years, the average has only been 2·9 cwt, a decrease in the production of somewhat more than one-third." Again the deficiency in value of crop has been variously estimated—"the average *Annual* deficiency in the whole Island has been estimated by some, as at least £2,000,000 and since the disease made its appearance in 1869 the coffee enterprise has suffered to the extent of from £12,000,000 to £15,000,000 in crops alone." Native Vol. 20, p. 358.

The prolific yield of this coffee is also a characteristic much dwelt upon. In the preceding sections the opinions of experienced planters who visited Liberia and saw the crops on the trees are fully given. There can be, therefore, no doubt that in Liberia the coffee yields, according to the nature of the cultivation at the rate of from 8 to 20 cwts. per acre. Mr. Agar who had many opportunities of forming an opinion "is confident that trees properly cultivated would give 6 to 8 lbs. each, or from 22 to 30 cwts. per acre of 400 trees." That this is not confined to the coffee when growing in its native country, but is maintained under other conditions of soil and climate, may be seen in reports which have reached us from Ceylon and other colonies. At Mausawa, Ceylon, a tree was described in 1877, when only a little over three years old, as being nearly ten feet high "while it still bore its 1,200 large cherries, of which we counted 23 in one cluster." Subsequent accounts from that colony have fully confirmed the free growing and prolific character of this coffee. Recently an estate of about 100 acres (Wellawaya), was reported in the *Ceylon Observer* as bearing from "six to eight hundredweight per acre, some of the trees being less than 2 years old." At another estate, opened in 1877, at Kalutara "an average tree was found to bear 1,500 berries, which was calculated to be at the rate of 150 bushels to the acre, equivalent to 8·3 cwt of clean coffee."

In Dominica, Dr. Imray as far back as 1876, expressed his conviction that "the Liberian Coffee will in time take the place of our native coffee, if I may so call it....... The plant must be evidently very prolific. I counted as many as 18 to 20 berries, even more in the axils of the two opposite leaves."

Hitherto, the number of plants placed under favourable conditions in Jamaica, have been too few to allow of an estimate being formed of the approximate yield per acre. The plants now at the Castleton Gardens were kept for two seasons in the uncongenial temperature of the Cinchona Plantation (5 000 feet), but after removal to Castleton (600 feet), they have made satisfactory and rapid progress. Recently they were described as "beautiful and much admired objects in their dress of stately dark green foliage, laden with the pure white bloom among which appeared the ruddy fruit from the previous year." During the year 1879-80 some seven thousand seedlings were raised from the produce of these trees, and the cultivation is being rapidly extended, both at Castleton and at the old Botanic Garden at Bath. Another peculiarity of Liberian Coffee is dwelt upon which if found generally applicable to it will greatly increase its value. The tree is mentioned as possessing the habit of sending its "strong tap-root far into the ground" and this characteristic is believed "will enable the Liberian Coffee to live and bear fruit in seasons of protracted drought, which prevent the setting of blossom on the ordinary coffee at low elevations."

We have omitted some useful hints on the cultivation of this coffee, but shall return to the subject shortly.

PUNJAB FOREST ADMINISTRATION.

READING over the above publication, we notice that the Conservator complains he has not sufficient assistants to enable him to carry on the work of conservation in a proper manner.

Why does he not endeavour to obtain European contractors, of small means, to fell, log, and launch his logs; convert his logs into sleepers and launch them; sweep the rivers annually and bring into the depôts every stick of wood they find floating about the rivers; make the necessary slides, roads, and paths; and otherwise make themselves generally useful—for a just consideration. By giving these operations on contract, the services of the officials of the F. D. would be released for the purposes of their own proper work, *viz*, demarcating forest tracts, drawing up their working plans, marking the trees to be felled, by the contractors, counting the logs or sleepers on the rivers' banks just when ready to be launched, and otherwise only supervising work which now has to be done in detail to the detriment of the work of conservation.

Or men with larger capital might be induced to buy the standing trees from the Forest Department, at so much for each one; performing all the operations beforementioned themselves, and on arrival in the plains selling the timber on their own account, and thus recoup themselves for their outlay in forest and river; of course, all expenses connected with slides, roads, &c., being paid for extra by the F. D., by whose officials the works to be constructed would be aligned. By adopting this plan the F. D. would be saved the necessity of keeping up depots in the plains for the sale of timber, the officials now engaged in such like operations (of petty trading, quite unworthy the notice of a ruling power) would be at liberty for transfer to arborescent plantations and other operations connected with the conservation of forest tracts. The F. D. would thus make its profit by the sale of the trees, instead of by the sale of the wood: the same income being derived from either plan, but at a less expenditure by adopting the above suggestion.

Then we notice that the conservator complains that the quasi-independent chiefs of the Hill States in the neighbourhood of Simla cannot be induced to conservate their forest, but *deboising* their territories till now very little more timber remains. And yet the Forest Department have a very strong remedy to apply to—in a great measure—put a stop to this wasteful denudation of the forest tracts of the Hill States, *viz.*, let the Forest Department establish a timber depôt at Suni, in the territory of Rajji, about 16 miles from Simla, and let them dispose of their timber there at such a rate that when it is delivered in Simla it will be 10 per cent. under the prices now obtained by the petty Rajahs, and the sales of their timber will soon cease, and thus afford rest to their forests which are now so unmercifully being destroyed.

Something must be done to save the forest tracts of those petty Rajahs from being cleared off the face of the earth; conservate they will not, so long as they can obtain rupees for their trees, and then there are so many vested interests—official and non-official—which have to be thrust on one side that the Forest Department will have all manner of difficulties put in its way in the establishment of a Timber Depôt, at Suni, and only by great firmness on the part of the conservator, personally supported by the Lieutenant-Governor of the Punjab, is it possible for the depôt to be established.

We also notice that the officials of the Forest Department, as regards the unenclosed forests are to be placed under the orders of the district officials, thus neutralising any benefits which would otherwise have ensued for the proper conservation of such tracts of country, as the Amlah of a District Court find it profitable to wink at encroachments on or destruction, of such places so long as they can find employment for relatives and friends as guardians and watchers, receive their perquisites, which they would lose were the unenclosed forests to be made over to the Forest Department; and they have sufficient influence with the district (European) officials and through them with the Government, to prevent the transfer.

For the same reason jungle fires will never be put down until the culprits are fined by the Forest Department, as the district officials take no interest in the matter, from not comprehending the mischief done by these fires, the whole subject connected with which has been repeatedly ventilated in this journal, that nothing further need be said about it here.

SUGAR-CANE.

Communicated.

SUGAR-CANE, *Saccharum officinarum* (vernacular *Parma Kamand*) seems to have been cultivated in India from a very remote period, though unknown to Europeans before the fifteenth century. In the year of Grace 1700, the consumption of sugar in Great Britain did not exceed 10,000 tons, whereas in 1875, the amount imported into the United Kingdom, was 918,727 tons. Some approximate returns prefaced for the Board of Trade showed that the total production of cane sugar of the world in 1876, amounted in round numbers to 2,140,000 tons.

Besides being grown in India, sugar-cane is largely cultivated in Brazil, Peru, West Indies, the Southern States of the Union, Egypt, Zanzibar, Natal, Mauritius, Java, China, Reunion, Central America, Mexico, and Australia.

Of the numerous kinds of cane known to the commercial world, there are perhaps not more than six or seven ever met within India. The sugar-cane had once rather a dangerous rival in the beetroot. Great exertions were made in Europe in the hopes that the root might supersede cane sugar, and eventually drive it out of the market, but the beetroot has attained its highest development.

The total outturn of beet sugar in 1876 did not exceed 1,320,000 tons, to quote an eminent authority. "The beet growers by acting according to good judgment, have devoted so much attention to the selection of the richest varieties of their plant, that they have raised its saccharine strength 8 per cent. within last fifty years. On the other hand it is undeniable that cane-growers have remained content with the gifts of Nature, and have done very little towards raising the quality and productiveness of their plant. The humble roots which rivals the cane has been doubled and trebled in richness, whilst the sugar-cane has remained comparatively stationary. It is asserted by many able to decide the question, that beetroot has now reached its maximum of sugar-producing quality, and we ought to be encouraged in our efforts to improve the cane by the knowledge that this plant *has not* reached its maximum of production."

The above remarks are as regards India only too true, both as far as the quality and quantity of its sugar are concerned. According to statistics quoted before, out of seventeen great sugar-growing countries, Cuba heads the list with a produce of 700,000 tons annually, whilst India comes only fifteenth on the list with a produce of 30,000 tons.* It is no exaggeration to say that with a proper and rational method of cultivation India might with ease (without increasing the area at present under sugar cultivation, supply one-third, if not, one-half of the amount now produced over the whole world.

In British Guiana, 8 hogshead of sugar per acre is an ordinary crop 5,000 to 6,000lbs. (53 cwts.) per acre not extraordinary, and in some instances 8,000lbs. = 73¼ cwts. have been produced. In British India the produce seldom exceeds 15 cwts on the best land. In Trinidad the produce cannot be estimated at less than 25 cwt per acre.

India like all other tropical countries is ages behind Europe and civilised America, in the development of its staples, sugar-cane, and its cultivation is mentioned in the Rig Veda, but like every other staple in the hand of the ryot, has deteriorated. It is only a question of time, and in many places its cultivation will be discontinued altogether with his cattle degenerating, his soil getting more and more exhausted, and as an inevitable consequence the percentage of saccharine matter in the cane decreasing, the unfortunate ryot will one fine day arrive at the conclusion that it will no longer pay him to cultivate this once valuable crop.

The following notes on sugar-cane cultivation as practised in the Jullundhur, Doab, and Manjha (Bari Doab) would apply perhaps to almost the whole of India, the seasons for sowing and harvesting excepted.

The kinds of cane grown in these two Doabs are known as (I.) Ekar (II.) Dhanlu, (III.) Chan, (IV.) Kanárá, (V.) Téru, of these five kinds Ekar produces the hardest cane, marked with dark bluish streaks. The other kinds Dhanlu, Chan, and Téru are comparatively 80ft. Téru gives the thickest cane, but Dhanlu the largest proportion of juice, and the latter may be distinguished by its greenish color ; Kanárá and Chan by a reddish brown color.

Chan and Kanárá yield the best "Pachhi" or fibre (after crushing) suitable for well ropes and inferior description of cordage.

Previous to sowing, the land is ploughed up ten or twelve times, and if the cultivator can afford it, he *ploughs?* in about 200 maunds of manure per acre, few however can manage to procure this amount. The manure consists of half-rotted farmyard dung, dried leaves, grass, straw, &c, in fact a *very* inferior kind of compost prepared without any care.

The cane is sown in spring sometime before the end of March. During the hot weather it is watered (*i. e.*, where well irrigation is available) about over a fortnight, till the setting in of the rains, should the monsoon cease early, as is very often the case in Upper India, the canes should be watered till the middle of the month of "Asu" about 1st of October.

The cultivator hoes the ground between the canes to eliminate weeds. When the canes approach maturity, three or four are generally tied up together to afford mutual support against the action of high wind.

The cane is harvested some time between November and the end of February, though in some parts it is not uncommon to see the cane standing in the fields in March.

The average yield of cane is about 350 maunds per acre, one-third of this is the average weight of juice.

100 (one hundred) maunds of juice will produce 20 maunds of Gur and 22 to 23 maunds of *rab*, which latter will yield 40 per cent. of sugar.

The cost of cultivation is about Rs. 30, and the clear profit varies from Rs. 20 to 25 per acre.

The diseases to which sugar-cane is liable, are called (I.) Parúna (II.) Téla (III.) Hadda (IV.) Kora.

The presence of Parúna or Ghúrlan I., may be detected by the shoots and leaves withering up, this process begins from the top, working its way down joint by joint to the very roots. If the rains are late in setting in, this disease shows itself about the month of Har (Asar) from July, and it is said that copious well irrigation only modifies but does not wholly avert the blight. It is also known to develope itself in "Asu" September to October, but then only when the monsoon ceases early.

II. Télá is also an insect blight. The insects though the same in size and shape, are of two distinct colors, black and grey, dotted with brown spots, this last is called "Chitta" or white. The blight is called Télá from Tél oil, on account of the peculiar greasy appearance presented by the cane and the leaves when attacked, which makes them look as though they had been dipped in oil or mucilage. The "Télá" generally makes its appearance in May or early in June, but is killed off or soon vanishes should the rains set in early in June, but if the blight comes in the form of the "Chitta Télá," the cultivators affirm that there is no remedy save burning linseed oil and cotton seed in open pans in the fields. This, however, is doubtful, and in either case the produce is scanty and of inferior quality.

III. Hadda from "Had," a bone. This form of disease shows itself in the total absence of juice, and is caused by cultivating cane on marshy or badly drained land, for this there is no remedy, save in a permanent improvement of the land.

IV. Kora. This can hardly be termed a disease, being in reality nothing more than the action of frost on canes which have been insufficiently irrigated the remedy is obvious.

Sugar-cane is also liable to attacks from swine, jackals, porcupines, and rats. White ants also do great damage. White ants are disposed of by extensive hoeing and liberal watering, rats by poison or smoking out by sulphur.

It is not only in the actual cultivation of the cane that the ryot is such a loser, but in his after manipulation of it. What can be more barbarous, filthy, and utterly unscientific than the "Behea," or its ruder brother the "Kolu." The Behea is a rude heavy machine, worked by eight bullocks (sixteen are required for a working day of eight hours). In plain language the Behea is a machine which requires a maximum of motive power giving out a minimum of useful effect. The bundles of cane have to be passed from ten to fifteen times between the rollers before all the juice is extracted. It costs about 8 annas per maund to extract the juice by the Behea or native mill.

The raw juice is boiled up in open pans cooled and refined, though it must be borne in mind that the finished article is not put into the market till perhaps the following autumn. The refining process being most tedious and unsatisfactory.

Sugar-cane is the most exhausting crop the ryot grows, demanding great care and attention.

The cane requires a deep tilth, and if this cannot be attained by ordinary ploughing, the soil should be worked up with a spade or phowrah, as is done in Natal, South Africa, and China. Manure to the extent of at least 15 tons per acre should be "forked in" to the soil. A very good compost, one which will answer admirably, can be easily made up from the following substances. Farmyard dung, leaves, weeds, poudrette, scrapings, vegetable refuse, slimy mud from the beds of tanks, as well as the weeds growing therein *Hydrilla verticellata*, *Potamogeton hisups*, *Vallenerria spiralis*, &c. This compost should be made under cover and well rotted before application, after having ploughed or forked in the manure The field should be carefully marked off into a series of ridges and furrows ridges to be not less than three feet apart from centre to centre, x ... 3′ ... x ... 3′ ... x 3′ x ... 3′ x 3 x and the difference of level between crest of ridge and bed of furrow should not exceed 9″.

These ridges can be raised by means of a native scoop or *Karaha*, or by using a ridging plough fitted up with double breast or mould board.

The canes should be planted along the crest of the ridges at intervals of 12 inches.

As soon as the plants appear above ground, the field should be well weeded, and the young shoots ought to get a dose of mineral manure, wood ashes, pounded and calcined bones, and salt mixed in the ratios of 6 4 : 1 respectively, will be found very effective. Each shoot should get about two ounces of the mixture, and then be earthed up about two inches.

If the field is kept well hoed, free from weeds, caked or puddled earth broken up after each watering, four waterings ought to be sufficient for the crop from 1st of April till the middle of June, by about which time the rainy season may be expected.

During the rainy season the advantages of having converted the field into a series of "ridges and furrows" will be appreciated, water will run off and not stagnate. Good surface drainage in a cane-field is highly essential.

Should the rainy season terminate early, the field should get another and final watering about the end of September. Early in November the crop should be fit for cutting.

* This means the amount exported only.

With care and good cultivation it is quite possible to raise from 700 to 850 maunds (25 to 30 tons) of cane per acre. Though it is on record that a growth equivalent to a fraction short of 50 tons per acre has been raised.

In the vicinity of towns and large cities where sewage irrigation is available, there is no reason why such results should not be realized. In such cases, however, the cultivator should see that he can ensure a thorough drainage *surface* and *sub-soil*, otherwise his canes would be weak and trashy, and utterly unfit for use.

Sugar-cane is such a thoroughly exhausting crop, that the ryot in Upper-India never attempts to grow it on the same land more than once in every two years.

Sugar-cane is as a rule followed by a *rabi* fallow, with maize or sorghum as a *kharif* crop, another *rabi* fallow, after which cane is again put down.

A very good method of preparing the ground for cane, would be to plough in a crop of young gram *Cicer arietnum* or *Sanpi Melilotus Paurflora*, but here the ryots' prejudices stand in the way, as he looks upon green manuring as little short of a downright sin.

The following points are worthy of notice in sugar cultivation :—

I. Provided the canes have not been frost-bitten, they can be cut and stored away under cover for some time without deterioration or affecting the quality of the juice.

II. Salt or sea water irrigation does not affect the cane injuriously.

III. According to Professor Simmonds " 1,240 gallons of juice at 8·5° Beaumé produced on a plantation 1,048lbs. of sugar, and 480lbs. of molasses, one gallon of juice at 8·5°B=8·76lbs. Avoridupois, ∴ 1,240 gallons of juice=11,111lbs.

100lbs. of cane=90lbs. of juice, then 11,111lbs. of juice are produced by 12,345lbs. of cane.

At 8·5° Beaumé juice contains 15 per cent of pure dry sugar, consequently 11,111lbs. of juice will produce 1,700lbs of sugar.

When the sugar is taken to the boiler, it is combined with water of crystallization, which being added to the 15·3 per cent. of pure and dry sugar=17·595 per cent. of sugar and molasses ; of this three parts are sugar and two parts are molasses, and we have for the 11,111lbs of juice at 17·575 per cent.=1,655lbs., of which 1,173 are sugar and 482 molasses.

IV. In Louisiana 13,000 to 4,500 canes per acre are produced with a length of cane varying from 3 to 8 feet, and average weight=10 ozs per running foot.

Canes 4·5' long would 3lbs and growing 350 per row of 100' long would give 61,125lbs per acre, but the average outturn may be put down at 60,000lbs.

V. In the production of sugar the division of labour should be carried out as completely as possible, or in other words it does not pay the planter to convert his own raw material into the market article, and that he should devote himself to the cultivation, improvement, and development of the staple, only unless he has considerable capital, and at the same time cultivates cane to a very large extent, he cannot procure the plant requisite to enable him to turn out the finished sugar as economically as is done in a large " Usine" or Central Factory. The following is a description of sugar cultivation in British Guiana.

A sugar estate is divided into fields of from 5 to 10 acres in extent by a series of cross canals, and the method of planting the cane is simple and easy when labor is at command. The brushwood and grass having been cut down and weeded, are piled into rows 6 to 8 feet apart across the intended beds into which the field is to be divided. These beds are found by digging open small drains 2 feet wide and 2 feet deep, at intervals of every 30 or 36 feet, across the entire field beginning within a few yards of the canal in the centre of the estate, and running to the side draining trenches into which they empty themselves. The soil from these small drains having been carefully thrown upon the beds so as to raise and round them off in the middle, narrow banks or ridges of earth are made across them from drain to drain parallel to and equidistant between the rows of grass and brushwood ; and in these spaces between the ranks of earth and grass, the canes are planted in line, each line being 3 or 4 feet apart, and each plant 9 or 10 inches from the next

The plants are procured by cutting off the tops or upper points of growing canes into lengths of 10 or 12 inches, which are thrust in a slanting direction into the well-stirred ground, and in ten days or so the long-grass-like leaves begin to spring from the eyes at every joint. These young canes require to be kept well weeded, and moulded about the roots from the ridges of earth or decaying grass on either side of them, which had been previously prepared for that purpose ; and this must be repeated as long as there is room for the labourers to pass between the rows, which, according to the season, will be until all the plants have attained the age of six or eight months, after which time the spreading of numerous leaves from each stook will have covered the surface of the field with so dense a jungle as in a great measure to prevent any further growth of weeds. When about nine months old, the cane throws out its "arrow," a long reed-like stem surmounted with a tuft of waving downy blossom. At this period the plant is poor and weak, and little more than a mass of water ; it soon, however recovers, and in twelve or thirteen months from the time of planting, is considered at maturity, having then sometimes attained a length of 20 to 25 feet, but more frequently of 10 or 12 feet about as thick as the wrist, and divided into points like a bamboo. When ripe, the canes are cut down to the ground in lengths of 3 or 4 feet, and thrown into punts which are towed along the canal by mules or oxen to the wet dock at the door of the sugar mill. Immediately after cutting the large quantity of thrash or dry leaves is rolled clear of the cane stumps, and heaped in rows, there to decay and form a rich manure for the succeeding crop. In a few days the stumps throw out their shoots, and the same routine of cultivation is repeated for twelve months more, any vacant spaces where plants may have missed being carefully supplied. The canes of the first year are called " plant canes" those of the second and subsequent years being distinguished as ratoons ; and these ratoons have been known to be produced from the first plant for twenty years and upwards, the canes having been annually cut down and the stumps allowed to shoot again. But this continued reproduction from the same stocks, which is now compulsory on the planter from the scarcity of labor, of course causes the canes to degenerate and to yield less abundantly. An acre of newly planted land will give two tons of sugar the first year, gradually falling off to not more than one fourth of that quantity as the stocks become old ; and were there sufficient labour in the Colony to admit of the land being replanted every third or fourth year, there can be little doubt that the present crops would be nearly doubled.

The productive power of the greater part of the soil in British Guiana, indeed appears to be unlimited. As an instance it may be mentioned that on an estate in Essequibo, the return obtained in 1851 from certain lands which had been properly worked and *perfectly drained* amounted to a fraction within 4 tons of sugar per acre."

There is not, cotton and tobacco not excepted, a wider or more fovorable field for European enterprise in India. The demand for the sugars known in Upper India as Nos. I. II. III. Shahjehanpur, is steadily increasing even amongst the natives who find that the factory-made article is cheaper than the bazaar commodity, and the day it is to be hoped is not far distant when those saccharine abominations sold in bunyas' as shops, and known by the names of misri, chini, khand shakar, &c., will be driven out of the market to give place to more wholesome commodities. Native liquors distilled from impure and filthy *gur*, toned and doctored up with kikar bark, peppers, &c., will, we may safely assume share a like fate.

Like tea, cotton, indigo, tobacco, coffee, &c., it will require European capital energy and supervision to develope this promising industry and it would be by the system of advances to cultivators. Premiums and prizes awarded for the best crops, together with the scientific cultivation of a few acres of cane attached to the factories, that the ryot would be induced to attempt improved methods of sugar cultivation.

In Upper India and the Punjab, there are numerous districts in which sugar factories would be found paying speculations Karnal, Umballa, Loodhiana, Jullundhur, Hosiarpur, Gurdaspur, Amritsar, Lahore, Muzaffarghur, Mooltan, and Shahpur, being the chief sugar producing districts of the Punjab.

In 1854, Captain Farrington, then Deputy Commissioner of Jullundhur, ascertained that the total sugar production of his district was equivalent to 600,000 maunds, valued at Rs. 9,99,000

In the same year, Hushiarpur was calculated to produce nearly 40,000 maunds, though within the last 27 years there is reason to believe that Hushiarpur has fully equalled, if not surpassed Jullundhur in its sugar production.

At Madhopur in Gurdaspur district, a large " Usine" has been started, conducted on correct principles, it should be not only a financial success, but a great boon to the country at large. In Mooltan it was reported as far back as 1854, that a " Refinery on the European system could be advantageously carried on "

Deputy Commissioners of Jullundhur and Hushiarpur in reporting on their own districts were of the same opinion.

The well-known Obaheite cane was introduced into the Muzaffarghur district, several maunds being distributed *gratis*, but the cane not being properly cultivated, died out in two or three years. In Muzaffarghur the return of sugar from country cane was 14 maunds per beegah of 6 kanals, 10 kanals=1 acre.

In conducting the business of a refinery or " Usine,' it may be taken for granted that the conditions on which the factory would purchase the cane would be similar to those prevailing in the European colonies in the West Indies, namely, that for every 100 maunds of cane the cultivator would receive from the factory the money value of so many pounds of sugar of a certain standard (which we will assume to be that known in the Indian market as No III. Shajehanpur). In other words for every 100 maunds of cane A supplies to the " Usine," he gets

the value of x lbs of sugar: x being taken at a figure varying from 3 to 5 according to circumstances.

Let us assume x=4, and that the crop weighs 700 maunds per acre, also that the cultivator lives about 10 miles distant from the Usine.

Carriage to Usine being defrayed by cultivator, and costing him 2 annas per maund.

His profit and cost of cultivation will be somewhat as follows :—

COST OF CULTIVATION.

	Rs.	A.	P.
Government revenue	2	0	0
Seed	5	0	0
Tillage operations	15	0	0
Manure 25 tons at 12as. per ton ...	18	12	0
Irrigation during summer months ...	10	0	0
Weeding, hoeing, &c.	5	0	0
Mineral (Bone-dust ashes, &c.) Manure ...	10	0	0
Reaping the crop	15	0	0
Carriage of 700 maunds of cane to Usine at 2as. per maund, say ...	90	0	0
Add 5 per cent. for wear and tear of stock, well gearing, &c.	15	0	0
	185	12	0
Contigent and unforseen expenditure at Rs. 10 per cent.	18	0	0
	203	12	0
Receipts by sale of 700 maunds of cane. Four per cent on 700=28, and the selling price of No. III Rs. 15 per maund	420	0	0
which represents his profit per acre as ... Rs.	216	4	0

Such a crop is impossible some may say. Not at all, when we are assured that in the Bombay Presidency on a Model Farm a growth equivalent to over 49 tons of cane per acre has been raised or something like 40,000lbs. higher than the average yield of a Louisiana plantation, Louisiana being one of the best sugar-producing States of the Union.

It may also be argued would the supply of cane be sufficient to keep the Usine in full work during the season and enough to enable it to turn out about 1,000 to 1,200 tons per mensem. Judging from results which the establishment of other industries have shown, it may be confidently predicted that in such a case the demand would create its own supply, and very probably it might just happen that the Usine would be suffering from a plethora of cane.

The Usine would be a highly popular institution with the cultivators because :—

a. It could afford to be more liberal in its terms than the "Shah" or village bunnia, paying a higher price for the canes, and at the same time it could also afford to make advances *without* interest, thus cutting the ground completely from under the bunnia's feet

b. The cultivator could cut and cast off his canes at once as soon as they were ripe to the factory.

7. The great wear-and-tear of live-stock entailed by crushing out the juice with native implement would be lessened and done away with.

8 The establishment of a factory would soon result in the improvement of communications, roads, bridges, as well as tanks, &c., and the natives would soon find their interests and those of the European settlers to be identical.

Would a factory or Usine pay if established in a good sugar-producing district. On this question there can scarcely be a doubt. In the French and English West Indian colonies where labor is expensive and coal fuel equally dear, Usines have paid on an average from 25 to 30 per cent. In India, however, labor is cheaper than in the West Indies, though coal fuel is undoubtedly dear, specially in Upper India. The machinery would have to be made either in England or France, and the capital required would vary from 5 to 6 lacks of rupees.

The following figures speak for themselves and represent an average stock, after collating the account of the three largest Usines in the Island of Martinique, "La Renty." Francois "Pointe Simon" which have paid 27·33$\frac{1}{3}$ 48 per cent. respectively on declared capital :—

Number of lbs. of canes ground per.		Cost per Hogshead.									Net profit to Usine per Hhd. of 1,102 lbs.		
Hhd. 1,102 lbs. of sugar.	100 lbs. of sugar.	Canes.			General expenses.			Total.					
		Frs.	cts.		Frs.	cts.		Frs.	cts.		Frs.	cts.	
14,308	1,300	146	57		76	68		222	26		115	73	
		L.	s.	d.	L.	s.	d.	L.	s.	d.	L.	s.	d.
Equal in sterling to		5	16	5$\frac{1}{4}$	3	1	4	8	17	9$\frac{1}{4}$	4	12	7

In a sugar factory the consumption of fuel is a most important point, as it constitutes one of the chief items in working expenses. "In the West Indies the consumption of coal has been reduced to a quarter of a ton of coal per ton of sugar produced ; but this is in addition to the megass, and triple action concentrators are in use."

Messrs Ransomes, Sims and Head, in their engines worked with vegetable refuse as fuel, steam cut off at from $\frac{1}{3}$ to $\frac{1}{4}$ of the stroke, found the proportion of consumption of coal to megass to be as 1: 2·96 which means that from 17 to 20lbs. of megass per H. P. per hour would be consumed in an engine of this description.

There are other substances such as straw, grass, maize, and cotton stalks, which could be used as fuel and procurable at a very low price, thereby precluding to a great extent, if not wholly the necessity for procuring coal which in Upper India must always be very expensive. A factory in a good sugar-producing district could in addition to sugar, always turn out a supply of good wholesome spirit, suitable for local or native consumption, in other words the factory could take the "Abkari contract" for the whole district, paying Government a higher sum than any native contractor, and at the same time supplying the native public with a pure good liquor at a cheap rate.

If the Aryan brother is to drink spirits, it as much to the interest of Government as to the interest of the people themselves that they should drink something wholesome, instead of the trash now vended in the "*Buttall's*" shops, a mess consisting of distilled juice, mixed with peppers and bark of kikar trees, the latter substance being added to impart a "*tone* and *body*" to the liquor.

The advantages to Government and the State at large, from the establishment of such factories in various parts of the country would be immense, both directly and indirectly. It would mean a large influx of English capital into the country. It could go a great way towards developing a very important industry. It could go a great way towards introducing an important and much desired agricultural reform, and last though not least native society could "be both accelerated in development, improved in quality, conciliated in sympathy by the presence of a large number of respectable non-official Englishmen, resident in the country, and as interested in its progress as the natives themselves. Such an element must largely avail to leaven the mass to tract improvement by example. to encourage enterprise and self dependence, and to disseminate Western ideas broadcast throughout he land."

EDITORIAL NOTES.

THE "Tea Cyclopædia" which has recently been issued from the office of the "*Indian Tea Gazette*" is well worthy of a place among tea literature. It does not pretend to tell us anything new, being avowedly a compilation. It is none the less useful on that account. Much has been written on tea of late years, and a large proportion of this writing has been the result of practical experience, and the work of practical men. This is the sort of information we want, not theorising, by people who have never seen a tea plant, but who smother us, and blind our perceptive faculties with a display of scientific terms. The Editor of the *Indian Tea Gazette* has done good service by collecting the best of this information, and placing it before us in a readable form. By means of a copious index, we can now at a moment's glance turn to any branch of the subject, and find the experience of several planters on that particular branch. It is not to be supposed that, because the book is a compilation, it therefore did not cost much trouble and anxiety to the editor. This is a mistake, careful editing is frequently of more value, when it exercises itself in cutting down and rejecting, than when it results in supplying "copy to the insatiable maw of the P. W., and we have to congratulate the editor of this volume on the skill he has shewn in deleting extraneous matter from the articles he has indented on for his information. We trust that the tea planters will appreciate this effort as it deserves to be appreciated.

WE hear from Canada that a great deal of testimony in favour of growing sugar-cane, comes from various parts of the province. The cane will in all probability be largely cultivated next year. The crop requires less attention than Indian corn, and produces besides about 200 gallons of excellent syrup to the acre, and first-rate fodder equal to the best hay.

IF we judge by the late cattle-fair at Umritsur, we shall have reason to believe in the agricultural prosperity of the Punjab.

Upwards of seventy-five thousand head of cattle were brought to the fair, and of this number, about two-thirds were sold. As might have been expected, the majority of the purchases were for the frontier districts, which, during the last two or three years, have been swept of cattle for transport purposes. The prices ranged from fifty to sixty per cent. above those of last year. One of the most attractive features of the fair was a Norton's tube well, round which there always seemed to be a crowd of people, anxious to understand its working.

We take the following table from a recent number of the *Economist* :—

The fertility of New Zealand is very great, and for agricultural purposes the percentage recorded below would, were there no financial drawbacks, point irresistibly in favour of that country :—

Average Yield per Acre. Mean of Six Years	Wheat bush.	Oats. bush.	Potatoes. tons.	Hay. tons.
Victoria	13	18¾	3⅕	1¼
New South Wales	14¼	19	2⅞	1⅓
New Zealand	27¼	33	5	1¼
South Australia	8⅜	12¾	3¼	1¼
Queensland	12	10	2⅛	1·3
Tasmania	17⅛	24	3½	1¼
Western Australia	11½	16¼	2⅝	1¼

The average of these is 15 bushels, and we are surprised to find it so low, in a new country like Australia, in India the average is 14 bushels, but this must be remembered is only the *rabi* crop. The land is beside, frequently called on to produce a *kharif* crop as well, so that compared with Australia, which only produces one crop a year, our yield must be considered better than theirs.

A CORRESPONDENT *Gardener* revives the subject of the value or otherwise of weeds. The subject is of sufficient importance to warrant some further discussion. There can be no doubt that a vast amount of plant food is consumed by these weeds, and the question is, whether it is better to allow the weeds to grow—short of seeding point,—and then hoe them in as green manure, or to keep them as short as the supply of labor will admit of. We never had a doubt on the subject. The late Lord Palmerstone used to say that "dirt was matter in a wrong place." Much the same might be said of weeds, and the more encouragement one gives to his bushes by good cultivation and manuring, it is grievous to find so much of his labor running to weeds. We adhere to the plan of keeping them well down.

IN another column will be found an extract from an Australian paper on the subject of artesian wells. It would seem that there is no difficulty in getting water, and that at very shallow depths. For instance, we are informed that a well 42 feet deep is yielding 10 gallons a minute, and delivering it at a height of 10 feet above the ground, when first opened this well gave 50 gallons a minute, but owing to its not being carefully made, it has become partially choked, and the flow is now somewhat restricted. By securing good workmanship this 50 gallons might have been secured as a permanency. It may be remarked that 50 gallons a minute is equal to 72,000 gallons a day, and this would supply one inch of water to 20 acres of land every week.

THE subject of improved ploughs has taken a strong hold on the public mind, and several are in the market. At the present time a discussion is going on in the columns of some of our up-country contemporaries, as to what constitutes the best plough, each inventor naturally considering his the best. We would suggest that a public trial be arranged for, in order to have an authoritative opinion, the details of such trial might be subject of mutual suggestion by the parties concerned, and if the various inventors of ploughs for ordinary native use, are disposed to go into the question *con amore*, we shall be glad to undertake the organisation of the meeting. We think that a committee might be named, whose decision would carry weight. We would suggest some such constitution as the following. That each inventor shall name one gentleman to sit on the committee, and that the Agricultural and Horticultural Society of India be asked to name, say three members to be added to those selected by inventors. That the trial be under the supervision of the Agri-Horticultural Society, and that they be asked to frame issues which shall include every qualification which such an implement should possess, and that whatever expense may be incurred shall be defrayed by the inventors in equal portions.

AN article on the production of a "large quantity" of good milk will be found among our selections. This is a subject which seems to be utterly neglected in India. This is the more surprising when we reflect on the fact that milk enters more largely into the diet of the mass of the people here, than in other countries. The people of India seem to be perfectly satisfied if their cattle are just able to exist. There is no desire for improvement in any shape or form. In the matter of milk, no care is taken with the food of the cows, and where milk is so valuable, this subject is surely worthy of a little attention.

WE would draw attention to a rather lengthy article in this number on the subject of the sugar-cane. It is from the pen of a gentleman in the Upper Provinces, who has had considerable experience, and we can confidently recommend it to the attention of all interested in this leading industry. We say "leading industry" more referring to the portion that the sugar-cane ought to occupy among our crops, than that which it does occupy. Few crops pay the cultivator so well as sugar-cane, and we are convinced that lack of capital is the only reason why the rayat does not engage in its cultivation more largely. Let this be supplied by private or joint stock enterprise, and the face of the country will assume a new aspect, so far as cane is concerned.

A NATIVE correspondent tells us (*Civil and Military Gazette*) that Monday and Thursday have been appointed the days by the Government for the passing of travellers into the Khyber, and it has been proclaimed that it will not be held responsible for the safety of those who proceed on other than these two days in the week. But a paper published at Peshawur says, that the Khyber is again full of danger for the traveller and describes, as the first instance of breach of faith on the part of the tribes, a case in which it is said that one hundred sheep belonging to the inhabitants of Kuchi were carried away by the tribesmen from a post which is situated between Ali Musjid and Lundi Kotal. They were pursued and lost two of their men, but the sheep were not recoverable unless Rs. 100 were paid to their maliks. In another case the tribesmen made away with Rs. 1,100 and six women of a *kafila* of Badakh-shanis who had been staying at a place called Haftchah between Lundi Kotal and Dakka. It is said that Rs. 6,000 have been paid to the robbers for the ransom of these women, and that this sum is to be deducted from the allowance of the tribesmen.

THE Mysore Planters' Association, among other bodies, tendered an address of congratulation to the young Maharajah, and expressed a hope that the relation which had hitherto existed between them and the Imperial Government, would receive no wrench at the change. His Highness has replied as follows :— "I feel grateful for your address of congratulations on my accession to the rule of my country under the protection of her Majesty the Queen-Empress, and for your voluntary assurance of loyalty to my throne and person. I place a high value on the importance of the planting interest to the prosperity of the province. As you rightly observe, agricultural pursuits are the mainstay of the people in this country, and an enterprize like the coffee cultivation by a body of English gentlemen possessed of science, energy, and capital, must promote the prosperity of the country, and stimulate and develope the native industry. I accordingly assure you, gentlemen, of every support and encouragement from my Government ; and I would express my hope that the planters living and working amidst the native population, with that mutual regard and respect for each other's rights which is the peculiar characteristic of the British race, will be able to raise the status of the native agricultural population, and bring English knowledge and energy to bear upon them for their benefit in a way which it cannot be in the power of any Government to accomplish. Once more thanking you for your address of congratulation, I wish every success and prosperity to the enterprize with which you are connected."

We fervently hope that the following item of intelligence from the *Indian Herald* is based on a good foundation. Few things are more urgently wanted in India than an Agricultural Department: "It is stated on what appears to be good authority, that the Indian and Home Governments are now considering the advisability of resuscitating the Department of Revenue, Agriculture, and Commerce, which Sir John Strachey, to indulge a pique on the part of Lord Lytton, abolished a little more than eighteen months ago. It is said that experience has proved that the sweeping away of the department was a decided mistake."

MISCELLANEOUS ITEMS.

FLOWER SHOW.—The annual flower show came off in the Lawrence Gardens on the 8th instant. The roses shown by Mr. Wrench were very pretty. The Arbori-Horticultural Society exhibited 96 sorts of roses, but they were very indifferent in quality. The vegetable show was a greater success. Forty-four prizes in all were distributed among thirty competitors. The show cannot be said to have been a success, neither can it be said that any great efforts had been made to make it so.

NEWCHWANG.—Large quantities of native grown opium have arrived from all parts of the country—and the stock of Malwa (Indian), although not large, has become a drug in more senses than one, only about ten piculs having so far been disposed of. The day is rapidly approaching when opium will become an article of export from this province, and the occupation of the Anti-Opium League will be gone through circumstances over which they have no control.

THE New Zealand wheat crop is spoken of as above average.

TREMENDOUS snowstorms have suspended railway traffic in Russia.

THE present harvest of Cyprus is the best that has been known for many years.

DEATH to the sparrows continues to be the motto of New Zealand farmers. At a recent meeting of the Brookside Club, it was announced that 6,000 eggs had been collected during the previous fortnight.

THE area of England, Wales, and Scotland is nearly ninety thousand square miles. Assuming the whole of this surface to be covered with snow to the depth of one foot, and that a foot of snow is equal to one inch of rain, the amazing result follows that there must have been discharged from the heavens, in the form of snow, a weight of water nearly six thousand millions of tons.

M. PREVALSKY, the Russian explorer of Chinese Tartary, is engaged in writing an account of his recent perilous journey in these unknown regions. When published, his book will doubtless afford much information of the highest interest to geographers and to the scientific world generally. In a recent letter to a European journal, he describes a rhurbarb plant which we imagine would be certain to take 1st prize at any European agricultural show. In one locality which he visited, he found this plant in prodigious quantities, and in some of the older plants the roots were of colossal size. Taking one at hazard, he found that it measured sixteen inches in length, twelve inches in breadth, seven inches in thickness, and weighed 26lbs. Vegetarians will be curious to know the exact locality of this favoured region where the root of a single plant can afford them an ample breakfast, lunch and dinner every day for a week.

A DISCOVERY which promises to have important results, has lately been made by a scientific gentleman in the neighbouring island of Reunion. He claims to have succeeded in solving the problem of extracting vegetable fibre from the Aloe or other leaves in an economical manner, and one which can be generally adopted. The principal features of the invention are as follows:—

The leaf is first placed for 10 minutes in a bath heated to 75° Fahr., and then removed to a second bath of water at its normal temperature, in which some inexpensive chemical substance (not yet made public) has previously been mixed. The leaves are allowed to remain some little time in the 2nd bath, after which it is said that the fibre can be washed out by women or children without any trouble. A Patent has been taken out for this process by its inventor in Reunion; and it is believed that one will be secured here immediately. The object of the researches, which resulted in this invention, was to obtain a means of cleaning the Ramie fibre; but the same process can be applied to the Aloe or any other leaf.

AMONG the new enterprises started here of late, I may mention that one of our wealthiest landed proprietors has lately begun Ostrich farming. Three or four pairs of these birds have been imported from Arabia and located on several hundred acres of this gentleman's estates which had been previously fenced and otherwise prepared for their reception. The ostriches have lately laid 12 eggs, so it may be presumed that they are satisfied with their quarters. Monsieur Lionard, the owner of these birds, has gone to a good deal of expense for their introduction, and has, I believe, good hopes for the ultimate success of his enterprise but what is wanted here is *experienced* attention to the birds.

IT is no doubt true that these two points are important, but what, of draught and efficiency of working. A plough may be simple in construction and cheap, but practically useless on account of the power necessary to draw it. This is the hitch in connection with any improvement in this direction, and from some correspondence which appeared in the *Express* we find that Mr. Martin and Mr. Phillips withdrew their ploughs from competition, because the *draught* was not to be taken into account. These gentlemen profess to have overcome the difficulty of providing a cheap, light, and simple plough which can do much more work than the country *hal*, without any appreciable excess of power being required, and it is a pity that they were not afforded an opportunity of submitting their ploughs to the test of working.

THE Lucknow correspondent of the *Civil and Military Gazette* has the following on the trial of ploughs at the recent exhibition:—

"The show of ploughs at Lucknow was very considerable, the chief exhibitors being "the Department," Messrs. Coen of Agra, Mr. Gavin Jones of Cawnpore, Mr. W. Martin of Etawah, and Mr. Phillips of Faizabad; but the two latter gentlemen withdrew from the competition, being dissatisfied with the conditions of trial. Our correspondent was sorry Mr. Martin's plough did not go to trial as it alone seemed to fufil one condition the Indian cultivator thinks much of, namely, that the man who holds the plough shall be within touch of the bullocks who drag it. A man is thus saved for each plough; whereas the other ploughs all required one man to hold the plough and another to drive or lead the bullocks. Perhaps, however, this would not have ensured Mr. Martin's success, for nearness to the bullocks was not one of the points taken into consideration by the judges, and two men were allowed for each plough. There seemed at first to be a good deal of uncertainty as to how the ploughs should be tested, and the soil was too light to admit of good work; but ultimately, a schedule of points, under the main heads of construction, working, and price, was drawn up, and each competing plough was separately worked and marks entered for each point in the schedule, according to the agreement of the judges. Capability of repair in this country, and price, were the main points which decided the competition, for several of the ploughs worked very well. The last sentence reveals a blot in the arrangements, and one which is fatal to any good results being obtained, or to any progress being obtained, or to any progress being made in supplying the ryot with a good plough.

FRUIT TREES IN BOHEMIA.—According to recently published statistics, the number of fruit trees in Bohemia of all sorts, but chiefly apples, appears to be 14,000,000. Of these 10,000,000 are in gardens, 1,600,000 in waste lands, and about 2,000,000 on the sides of the public roads. The number of young trees annually planted is about 1,500,000. Between 6,000 and 7,000 miles of road are planted with fruit trees, mostly of the best sorts, and the revenue therefrom is very large. The fruit is largely exported to the north of Germany and Russia.

A FREAK OF NATURE.—In Oceana county, Michigan, a large maple tree about 30in. in diameter stands about two rods from where one about 15in. in diameter starts from the ground, and both grew solid together at a height of about 40 ft.

THE LARGEST CHESTNUT TREE IN THE UNITED STATES.—This is growing on the farm of Solomon Merkle, at Berks, Pa., and is nearly 40ft. in circumference at the base. The top of the tree is reached without danger by steps that are fastened between the limbs. It is estimated that this tree contains about 17 cords of wood. It will yields about 300 bushels of chestnuts annually.

LARGE CEDAR OF LEBANON.—One of the finest specimens of this tree is to be seen in the garden of Mr. W. J. Lloyd, of Langleybury, Herts. It measures, at 4 ft. from the ground, 22 ft. 4 in. in girth, the branches extend over 105 ft., and its height is 107 ft. The weight of its branches after a heavy fall of rain or snow is such that each limb has been secured to the stem by iron rods to prevent them breaking off. Upwards of one and-a-half ton of iron have been used to secure it, and quite a network of iron is spread beneath the branches, so skilfully arranged as not to detract from the perfect and graceful form of the tree.

IN Great Britain the average produce of wheat, according to the best authorities, is about 23 or 24 bushels per acre, whereas in Guernsey, Jersey, and Sark, the average is 33 to 36, and on certain farms the yield has not unfrequently been as high as 54, 56, or even 60 bushels per acre.

CINCHONA bark for Venice, amounting to 47,611lbs., forms a prominent item in the list of exports from Ceylon recently.

CHAMPION POTATOES.—In the *Agricultural Gazette*. 'W. G.' Yorkshre, gives the result of his experience in the growing of champions. On a stubble field 35 cwt. of wool manure (Stanley's patent prepared) was applied per acre. The yield was 11 tons to the acre, and there was total immunity from disease. To the presence of kainit in the manure was attributed the fact that not a single worm-eaten potato was observed.

THE territorial extent of France is 132,000,000 acres, and of this 37,500,000 acres, more than one-fourth, is sown with corn; while

the area of Great Britain and Ireland is 77,800,000 acres, and the land sown with corn of all kinds is 11,000,000 acres less than one-seventh.

IRISH ESPARTO GRASS.—As foreign grasses used in paper-making are becoming scarcer than they used to be, attention is directed to the Irish product. *Nature* points out that in Ireland alone there are over 1,000,000 acres at the present moment not worth sixpence a year, each for any agricultural purpose; each acre would easily grow half a ton weight of dried melic grass, which at its lowest value would be worth £2. Would not this crop, in time, more than compensate for the loss of the potato? It seems a pity that the manufacture should have to go to the port of Mogador for what he might get with so much greater ease at the port of Dublin.

IT appears that a very great improvement in the process of breeding silkworms has been effected by the use of artificial heat. Experiments lately made in the division of Yofu, Prefecture of Hiyogo, are said to have been eminently successful, not only as regards celerity of hatching, but also in the quantity and quality of the silk produced. Hitherto the heat of the sun has been trusted altogether, and consequent variations of temperature have caused very uncertain results. A little attention to matters of this sort, supplemental by a Government edict prohibiting the export of silkworm eggs, would soon cause an appreciable increase in the export returns.

THE number of grain bags used in the transportation of California wheat, in 1880, is set down at 34,021,500.

THE total value of bread-stuffs exported from the United States in 1880, amounted to $263,295,359, against $239,201,899, in 1879.

THE grain exports from New York, in 1880, reached 107,000,000 bushels, an excess of nearly 13,000,000 bushels over the exports of any previous years.

EUROPE takes about 85 per cent. of the hog products exported from the United States. A small percentage is sent to Africa and to various islands in the Pacific and Indian oceans.

SUNFLOWER seed is recommended by some poultry fanciers as an excellent food. It is said to greatly increase the brilliancy of the plumage and also stimulate the production of eggs.

IT took only 400 horses to cultivate 24,000 acres of land in wheat, on the famous Dalrymple farm in Dakota, besides which 4,000 acres of raw prairie was broken—making 70 acres ploughed for each horse used.

The Utica, N. Y., *Herald* gives the result of converting 1,504 pounds of milk into butter by a new process, which gave 59lbs. of butter, (one to 25·5lbs., of milk), after which the skim and butter-milk gave 146lbs. of cheese.

POULTRY canning has become quite an extensive business at Dover, the capital of Little Delaware. In two days, November 22 and 23, one firm there bought 95,000 pounds, and had it all canned by the 27th, and some of it on the way to Europe. In four weeks the firm bought 240,000 pounds.

IN 1880, J. B. Bodwell, of Hallowell, Me., on a half acre raised "over four hundred bushels of nice turnips," says the Augusta *Farmer*. The land was drained bog, and had been treated to twelve-and-a-half bushels of unleached ashes, spread broadcast, with a sprinkle of superphosphate in the hills. The rows were three feet apart and eighteen inches in the hills. Growing turnips in "hills" would be a novel business for a western farmer.

MR. GLADSTONE ON BRITISH AGRICULTURE.—Mr. James Howard, M.P., has received the following letter from Mr. Gladstone, dated February 28 :—'Mr. Gladstone has had the honour to receive the resolution enclosed in your letter of the 23rd instant, which was passed at the recent meeting of the Hampshire branch of the Farmers' Alliance, in reference to the claims of British agriculture to the early attention of Parliament, and in reply I am directed to say that Mr. Gladstone is very sensible of the urgency of questions connected with land in England and Scotland, and he much regrets that they have been, for the present, thrust back from the immediate front of public affairs.—I remain, &c., E. W. HAMILTON.'

THE TOBACCO DUTIES.—A meeting of tobacco manufacturers was held at 31, Moorgate-street, yesterday, Mr. W. H. Wills, M.P., in the chair, to consider the question of the tobacco duties. The following resolution was unanimously carried :—"That so large a majority of the trade as regards number and amount of duty paid being in favour of a reduction of the duties on unmanufactured tobacco to 3s. 2d. per lb., this committee desires an interview with the Chancellor of the Exchequer on the subject." It was also resolved that Mr. Wills be requested to arrange for the reception of the deputation.

THE cultivation of osier-beds is attracting considerable attention in Rhenish Prussia.

SOME people imagine that farming needs but little outlay of brain power to make it successful. But as some one has truthfully said, "brains makes the best fertilizer a man can use."

I WISH to testify to the healthfulness of fruit. I have raised a family of six children and have allowed them to eat fruit of all kinds without stint, and if there is a family that has been raised with less medicine, or sickness, I should like to make their acquaintance.—*Cor. Live Patron.*

AN agricultural society in Maine has awarded a prize of $200 to F. E. Small, aged 16, for raising 2,256lbs. of corn in the ear, on an eighth of an acre; to Frank L. Jordan, aged 16, for 1,945lbs. $50; to Wm. J. Littlefield, aged 18, for 1,841¾lbs. The corn was all weighed in the ear "when ripe." The heaviest crop allowing 70lbs. to the bushel, would be at the rate of 257·84 bushels per acre of shelled corn. This crop was planted in hills ten inches apart with four grains in the hill—width of rows not stated. Value of manure applied at the rate of £72 per acre. The second crop was planted in hills eight inches apart and one stalk in a place—width of rows three feet. Value of manure applied $128 per acre. The corn was all of an eight-rowed variety.

THE FRENCH HARVEST FOR 1880.—The provisional valuations transmitted by the prefects fix the amount of the harvest for the whole of France, including Corsica, in 1880, at the following figures :—Wheat, 17,426,599,300lbs.; meslin (a mixture of wheat and rye), 1,060,625,060lbs.; rye, 4,102,928,060lbs.

THE gross income derived from the growth of tobacco by the United States farmers is estimated at about 22,000,000 dols.

OFFICIAL PAPERS.

REPORT ON THE ORES OF GWALIOR.

(*By Taj Kittirle Von Schwartz.*)

THE Gwalior *iron ores* are remarkable at once for their purity and their richness. They are chiefly red iron ores and magnetite, containing sometimes manganese, but there are also brown iron ores and siliceous hematite.

Magnetites contain 70 per cent. of metallic iron (or 68 per cent. oxide, and 29 per cent. protoxide of iron); the red iron ore from 60 to 71 per cent. of iron (or 86 to 99 per cent. of oxide of iron), the brown iron ores are from 42 to 54 per cent. and the siliceous hematites from 45 to 48 per cent. of iron metallic.

The few impurities of these ores are small quantities of quartz, clay and manganese, and exceptionally some lime; of sulphur there are but few traces; of phosphorus none: at least none have been discovered in the red iron ores and in the magnetites.

In general the European ores contain only from 35 to 40 per cent. of metallic iron. How great a value is put on rich and pure ores by iron makers may be learnt from the circumstances that vast quantities of such iron ores are yearly imported into England, France, Germany and Belgium from distant countries. In 1878, Bilbao, in Spain, shipped 1½ million tons of iron ores to Cardiff. Herr Krupp, the great gun-maker of Germany, has his own iron mines in Bilbao. France draws yearly 500,000 tons of iron ore from Moktas in Algeria, and England also imports large quantities from the same source. The exported ores of Bilbao are brown iron ores with 52 to 55 per cent. of iron, those of Algeria are magnetite and red iron ore with 69 per cent. of metallic iron, therefore from 10 to 12 per cent. and inferior to the Gwalior iron ores.

The red iron ores near Tantoro, Maesora, and Dharoly occur in enormous quantities on the surface of the ground; the erection of costly mining works is here not required.

These iron ores, containing as was said before, no phosphorus, are suitable for the production not only of bar iron, but especially of Bessemer cast steel for rails.

The ores containing manganese are especially useful for the production of that for cutting tools.

Equally the pure red iron ores containing manganese are suitable for the production of "Spregeleisen" specular cast iron), a kind of pig iron which is added to the iron in the Bessemer process, and in cast steel crucibles. America imports "spregeleisen" from Europe to the amount of 20,000 tons per annum; its sale price is in England £5¾, in America 43 dollars per ton (loco New York), also Cd. 50 per cent. higher than that of ordinary pig iron.

For converting these iron ores into finished iron or steel, there is ample wood available, as there is a large forest in the north-west part of Gwalior, at a distance of about 50 miles from the place, where the best and the largest quantities of iron ores occur.

This forest is bounded in the north by the river Chamba, on the west by the river Parboti, in the south by Khota, and Jhallavar territories, and in the east by the river Kunu. It lies on a plateau elevated about 1,000 feet above the level of the sea, covering 2,400 square miles. These forests may be counted upon to yield 15,000 tons of wood per square mile or about 56 millions of tons for the whole area, and would suffice to feed an iron work (one blast furnace with puddling and rolling mill) producing daily 12 tons of finished bar iron during nine hundred years, in which calculation the question of recoupment by natural growth and artificial planting has not been taken into account. If natural growth and artificial planting be taken into account, these forests can feed 40 blast furnaces with refining works for an indefinite period without being terminated.

There are great varieties of wood in these forests, about three quarters of them hard wood, which makes them more precious for smelting purposes, as the quantity of charcoal is proportional to its specific weight; and the harder the wood is, the greater is the specific weight of the charcoal made from it. The weight of the charcoal is 17lbs. per cubic foot and near the forests it may be had at the rate of as. 4 per maund. The German and Styrian iron works pay as. 12 per maund for charcoal weighing only 12lbs per cubic foot.

The chief advantage of wood and charcoal over mineral coal, as a fuel, consists in the greater purity of the former. The price of iron made with vegetable fuel is very much higher than that of iron made with mineral coal. Charcoal iron from Davemora in Sweden, has been known to fetch in Sheffield £14 per ton at the time when (iron made with mineral coal) was selling in the same place at £6 per ton. In Germany, charcoal pig iron fetches 160 shillings per ton, against 75 to 80 for mineral coal pig iron, &c.

Mr. Schwartz discovered fire clay near Girway and near Tisroon (about 35 miles, S. W. from Gwalior). This clay is not so good as English fire clay, but always good enough to make fire bricks for steam boiler masonry cupola furnaces, and such parts of the iron refining furnaces, where the temperature does not exceed 1,300° Centigrade.

Samples of the Gwalior iron ores of the different kinds of wood, and of firebricks made of Gwalior fire clay are at hand, and can be delivered by Mr. Schwartz if wanted.

List of Iron Ores

Occurring in H. H. Sindia's territory, discovered and analysed by Mr. Schwartz:—

Name of the villages near the place.	Name of specimen.	Average contented iron metallics in per cent.	How many miles from the forests.	How many miles from Gwalior.	Remarks.
Tantow	Red iron ores	66	50	7	Contents partly manganese. These iron ores occur in very great quantities.
Masera	" " "	68	50	9	
Gokolpore	" " "	65	50	2	
Dharoli	" " "	63	55	8	
Bamasri	" " "	66	50	10	
Raypoor	" " "	71	50	8	
Gokolpore	Magnetic ore	70	50	2	
Gurway	" "	66	50	8	
Besides these are others of inferior quantity &c.					
Binaseri &c., Baroda ...	Brown iron ores.	45	20	45	Contents manganese.
Tonilia		45	20	70	
Seeprie and Turwaya ...	Siliceous Hæma. &c., &c	48	34	64	Large quantities.
Goonjars, &c., Baran ...	Brown iron ores.	52	20	80	

THE NYNEE TAL LANDSLIP.

From Her Majesty's SECRETARY OF STATE for India,—To the GOVERNMENT OF INDIA,—No. 7 (Revenue-Forests), dated 20th January 1881.

I TRANSMIT herewith for your Excellency's information, copy of a letter dated 18th October 1880, from Colonel Pearson, proposing in view of the late disastrous landslip at Nynee-Tal, that Forest Officers who may be at home on furlough, should from time to time be deputed to visit the works in the Basses and Hautes Alpes for the prevention and repair of similar landslip on the sides of the Alps.

2. This suggestion seems worthy of adoption, and I shall be prepared to sanction the employment, on deputation, of any Forest Officer on furlough whom your Government may recommend for the purpose on the terms accorded to officers visiting works at the public expense.

From Colonel G. F. PEARSON,—To Her Majesty's UNDER-SECRETARY of State for India—dated the 18th October 1880.

I AM induced by the late disastrous landslip at Nynee-Tal to do myself the honor of addressing you, with a view if possible to the deputation from time to time of any Forest Officers who may be at home from India on furlough, to visit the works in the Basses and Hautes Alpes, especially near Barcellonette and Embrun with a view to the prevention and repair of similar givings-way of the mountain sides in the Alps. There are huge landslips in the Alps which have covered the vineyards and habitations for three to four kilometres along the bottom of the valleys, and have destroyed property to an enormous value, but which have been successfully treated by various works, and especially by planting the hills around and above them, thereby preventing the water, when there is a heavy fall of rain from forming a torrent which is the main cause of these catastrophes. Some of these landslips must be three or four times the size of that at Nynee-Tal, and it is impossible to suppose that the same means which have been effective in the Alps should not equally succeed there.

SELECTIONS.

CULTIVATION OF RAILWAY SLOPES.

THE project of the South-Western Railway Company to let the slopes on its line for cultivation, reminds me of the fine apple, pear, and I think peach and plum trees in full bearing I saw trained *en espaliers* to hurdles for miles along the line somewhere not far from Agen, ten years ago when I was on my way to the Pyrenees, and how I regretted the same plan was not pursued in England. Then, too, where cucumbers, melons, pumpkins, marrows, and other sun-loving plants could not be grown for fear of disturbing the soil in their culture, strawberries might be, wholesale, as their perennial roots would tend to consolidate the bank side, and the use which might be made of the now waste flats along our various line sides, to use a French idiom, " goes without saying." When hurrying past the pools and meres resulting from railway excavations, with the water hens and their callow brood mincing to and fro on them too, I have often thought at how trifling a cost these waters might be utilised as stews for pond fish, and as abodes and breeding places for more profitable fowl.—H. N. P. W. in *Land and Water*.

TO GET A LARGE YIELD OF RICH MILK.

THE " Farm," published in England, confirms our own experience in feeding milch cows with bran. "If a large yield of rich milk is desired," says the writer, "give your cows, every day, water slightly salted, in which bran has been stirred at the rate of one quart to two gallons of water. You will find, if you have not tried this daily practice, that your cows will give 25 per cent. more milk immediately under the effects of it, and will become so accustomed to the diet as to refuse to drink clear water, unless very thirsty."

Professor J. W. Sanborn, Superintendent of the College Farm, Hanover, N. H., reports experiments in feeding cows, giving full details of weights of each kind of feed, of milk and butter yield, and weights of the animals at the beginning and end of each period. In summing up, he says, "Meal will make more milk than bran. I no longer hesitate to say. The change in the butter is remarkable: in changing from meal to bran there was a loss of 17·7 per cent. in the butter-producing capacity of milk; in changing from bran to meal there was a gain in the butter-producing capacity of milk of 21·8 per cent. The results in weighing the cows form an exception to previous experiments, bran and middlings keeping weight better than meal in this experiment.

" Is it a chance result," asks the professor, " or is it due to well-defined causes? I will not discuss it," he answers, " but observe that it was at the season of the year when a cow needs a carbonaceous food to maintain heat, also the grass of our pastures was browned, and in different condition from June grass or properly-cut hay."—*American Paper.*

WHOLE-MEAL BREAD.

MISS YATES, Hon. Secy. of the Bread Reform League, writes from 17 St. Edmund's Terrace, Regent's-park, to *The Times*:—Will you allow me to call attention to the statement Professor Church made at the Mansion-house conference, that " the proper ratio in food for adult use was one-part of flesh-forming substance, to about five-parts of heat-giving substance, converted into its equivalent of starch, and in whole meal there is very nearly this ratio; but in white bread the ratio was 1 to 7½, even if it was a favourable specimen ?"

The great superiority of whole meal over white flour consists principally in the much larger proportion of bone-forming substances that it contains. Professor Church, in his standard work on " Food," states that whole meal contains 1 7 of mineral matter, whereas white flour only contains 0·7, and Liebig states that whole meal contains 300 per cent. more phosphatic salts than fine white flour. As it is these phosphatic salts which form bones and teeth, and nourish the brain, nerves, and tissues, it will be at once understood how essential it is that poor children should be able to obtain a bread which contains them—for their parents cannot afford to give them meat, milk, and eggs, to replace the phosphates and flesh-forming substances extracted from white flour.

The ordinary processes of milling reject about 25 per cent. of the grain. Professor Church states that only about 2·8 of the grain is innutritious so that 22 per cent. of valuable food is wasted in the manufacture of white flour. When it is realised that these rejected portions would feed, as Dr. Bartlett stated, many thousands of our paupers, the necessity for bread reform is very evident.

We do not, however, simply prove our case by mere chemical analyses. Considerable personal experience among Egyptian fellaheen and Sicilian peasants (who live principally on bread) has proved to me the truth of their statement that wheat-meal bread satisfied and sustains much better than white bread does, and that a much larger amount of work can be done on wheat-meal bread alone than on white bread alone.

As any one can easily put this statement to practical proof, we confidently appeal to the public to assist us in our endeavours to procure the general use of a bread which will enable every poor person to obtain proper nourishment, and give every child a fair chance of growing up strong enough to do his work in the world, instead of being a burden to society and a misery to himself.

ARTESIAN WELLS IN THE DARLING COUNTRY.

(From the Sydney Mail, Feb. 5.)

AT the last meeting of the Linnean Society, Mr. C. S. Wilkinson, the Government Geologist, being furnished with notes from Mr. H. A. Gilliat, Government Tank Inspector, imparted some interesting information regarding the progress of well-boring near the Darling River. Mr. Gilliat, on his recent visit to the splendid tract of pastoral country owned by Messrs. Officer & Co., was shown by D. Brown, the Manager for those gentlemen, on the Wee Wattah Station a bore down 142 feet, from which good fresh water of a temperature of 82deg. was flowing to a height of 10 feet through the four-inch pipe. [The machine employed is Wright and Edwards's Australian Water Auger.] This well, when first sunk, realised 50 gallons per minute, but owing to chokage by sand in a few days this quantity was reduced considerably, and when M. Gilliat was on the ground, the flow was not equal to one-fifth of the original yield. Wee Wattah is 18 miles north from the Darling, and is distant from Wilcannia about 80 miles. Close to the bore mentioned, there is a mud spring 40 feet in diameter, in which, although water does not flow from it, that fluid is always found. Near to this spring five bores have been put down, to depths varying from 134 feet to 142 feet. From all of these water has been obtained, but it is only the 142 feet bore, the one described above, which is now open, all the others were choked by the drift. The boring at Wee Wattah is through clay, and clay mixed with drift. At Mulyer, 14 miles north-east from Wee Wattah, and 24 miles back from the Darling, Mr. Brown recently put down four bores close to an old spring. All of these are running, although the pipes have, on account of the smallness of the supply, been drawn from three. In the last of these bores water was struck at 17 feet, and it is now flowing from a depth of 49 feet at the rate of 12 gallons per minute, its temperature being 63 deg. Fahr. The flow ceases at 4 feet above the surface; the pipes are 4 inches in diameter. At Gomery, 25 miles back from the river, on Messrs. M'Caughey & Co.'s Tourale run, there is a well bored to 100 feet which yields a small supply. Of this Mr. Gilliat has only meagre particulars. It is reported, too, that water has been struck by an artesian bore on the Gualla run, 60 miles from Wilcannia, and it would seem that there is among the lessees of the Darling country a disposition to expend large sums in thoroughly testing its subterranean water stores.

MONSTROUS FUNGI.

VISITORS to ancient wine vaults or damp coal pits are sometimes astonished by the curious fungi which drape the walls with gruesome tapestry; but every instance of this kind is thrown into the shade by the extraordinary growths which have recently been discovered in some of the deserted Mexican silver mines of Nevada, United States. The dank, warm timber galleries and drifts of these old workings, abandoned to themselves for years have silently given birth to a monstrous brood of morbid vegetation, which apparently, has no parallel in the regions of the sunlight and the upper air. In general they are all of a snowy whiteness, and some of the hooded masses rise up several feet from the ground like sheeted ghosts. Others, in the distance, take the form of bearded goats or sleeping owls. Here great bunches of long white hair hang down from the roof and there huge pulpy masses encumber the floor like bosses of brainstone coral. The latter appear to have sprung miraculously from something spilled upon the rocks in past days; while the former seems to have crystallised like hoar-frost from the atmosphere itself some of the roundd masses have actually lifted up from the floor blocks of stone weighing ten, fifty, and even a hundred pounds, to a height of three feet. In the higher levels of the mines, where the air is drier, the fungi are far less bulky than below, and much firmer in texture. The shapes here are, however, more elaborate and beautiful. One kind grows in a twisted spiral, like a ram's horn, to a length of five feet, and hangs from the rafters like a trophy of the chase or, rather, like a serpent suspended by the tail. Another sort sends out a stem the thickness of a pencil to a height of one or two feet, where it blossoms into a bulbous knob something like a flower. Nothing like the toadstool or the common mushroom is to be found, and the wonderous growths have all the aspect of being called into a special being by the peculartics of their environment.—*Globe.*

INDIAN WHEAT.

DR. FORBES WATSON'S Report of 1879 on the samples of Indian wheat forwarded from India has now been supplemented by a second Report on the samples received at the India Office last year from the Punjab. These samples show a marked improvement in quality and condition upon those formerly received. They are less weevilled, and generally worth more money, allowance being duly made for the rise in market values last year. The 192 samples averaged a value of 46s. 10½*d* per quarter, as compared with the former average of 39s. 8*d*. for all India. Only seven fell below 42s. while 14 per cent. of the previous samples did not come up to 37*s*. a quarter; and of these seven all but one came from Dera Ghasi Khan and Dera Ismail Khan. Their low value was due to "dirtiness" which includes an admixture of barley or other grain. Thirty-one samples of "soft white" ranged in value from 51*s*, to 46s. 6*d*. and in weight per bushel from 59lbs. to 65lbs. One of these from Muzuffargarh, is ranked with the "very finest" Oregon wheat; eight with "very fine" or "fine" Australian, four with Chilian, one with Californian and two are described as "extra No. 1." Not one is quite equal to the best Delhi sample of the previous report. Of "hard white" there are sixty-seven samples averaging 46*s*. 9*d*. a quarter against 39*s*. 5*d*. for all India in 1879. They range in value from 50*s*, for the Jhang sample and 49*s*. 6*d*. for one from Muzuffargarh down to 32*s*. for a very dirty sample from Dera Ghasi Khan. Their weight various from 54½lbs. to 60lbs. per bushel. The best of these are likened to pearl barley or to kuvanka, and only the five worst fall in value below 45*s*. a quarter. The "soft red" samples are thirty in number, ranging in weight for 58½lbs. to 63lbs. per bushel, and in value from 44*s*. to 48*s*. 6*d*. a quarter. Many of them are likened to No. 1 or No. 2 red winter, and the dirtiest samples come from Dera Ismail Khan, but these are better than the "inferior" sorts of 1879. Of the fifty-nine samples of "hard red," as many as fifty-eight range in value from 43*s*. up to 48*s*. 6*d*. a quarter, whereas in the former valuation none of them rose above 39*s*. a quarter. Allowing 8*s*. a quarter for the rise of market prices, we still have "a marked and characteristic advance" in the value of the present samples as a whole. The best come from Goojerat, Rohtak, Kohat, Jhang, Delhi, Gurgaon, Rawul Pindi, and even from Dera Ghazi and Dera Ismail Khan, while the last named also contributes the worst. More than half of them are valued at 47*s*. and upwards, and several of them weigh from 63lbs. to 64½lbs. per bushel.—*Home News.*

NOTES ON USEFUL PLANTS.

(From the Kew Report for 1879)

(Continued from page 103.)

The supply of India-rubber, or caoutchouc, is a question that has of late years occupied the attention of commercial, as well as scientific men. It has received a good deal of attention at Kew, as the following extracts from reports from various parts of the world will show:—

1. CASTILLOA.—SINGAPORE.—Mr. Murton reports:—"The plants of *hevea* and *castillon* in the gardens are now large plants, but hitherto propagation from the strong growths they are making, seems rather difficult, whereas they used to propagate freely from the weak wood produced while in pots."

2. CEARA SCRAP (*Manihot glaziovii*)—BURMAH.—Major Seaton reports:—"A quantity of seed of this India-rubber tree was received during the latter part of the season from the Botanical Gardens, Peradeniya, Ceylon; and at the request of Dr. Thwaites, an intelligent lad was deputed to Ceylon to receive instructions in the cultivation of India-rubber plants."

CALCUTTA.—Dr. King reports:—"The Ceara rubber promise to grow well in Calcutta. The seedlings received from Kew have thriven vigorously, and some of them are now 20 feet high. The Director of the Botanic Garden in Ceylon having, at the request of the Secretary of State for India, undertaken the propagation of this species, a quantity of seeds of it were distributed by him to Indian officers during the year. Supplies were, I understand, sent to the Conservators of Forests in Burmah and Assam, and to the Inspector-General of Forests for Madras. A large supply was received at this garden, and a thousand seeds were sent at the request of the Conservator of Forests for Bengal, to the officer in charge of the forest plantation near Chittagong. The seeds received here have begun to germinate, and I expect before long to be in a position to issue supplies of seedlings for trial in different parts of the country. The plant appears to thrive very well in Upper India, and if the quality of rubber yielded by it in this country turns out to be good, its introduction may prove of much importance."

SINGAPORE.—Mr. Murton reports:—"Ceara scrap rubber must be omitted from the list of rubbers adapted to the climate of the Malayan Peninsula, as it has invariably rotted off during continued wet weather."

ZANZIBAR.—Dr. Kirk informs me that with him the Ceara rubber yields seed most abundantly, but the seeds are slow to germinate.

3. HEVEAH.—BURMA.—Major Seaton reports.—"At Mergui eight Para India-rubber trees, the survivors of the batch of seedlings received from Dr. King in 1877, continue to do well in the office compound, and vary in height from 8 feet to 25 feet.

They are large enough to admit of a considerable number of cuttings being taken from them."

CALCUTTA.—Dr. King reports:—"Para rubber, of which 14 plants were alive in the garden at the date of last report, continues to be as disappointing as ever. Most of these 14 plants are still alive, but they have not grown much, and; it is quite clear to me that it is vain to hope that this species can ever be cultivated to profit in this part of India. Plants may be coaxed into growing in conservatories, but the species is by far too thoroughly tropical to withstand without protection the vicissitudes of the climate of Northern India. As I have before reported, I believe it is useless to try it any where in India, except in the south of Burmah or the Andamans, and perhaps in Malabar. I learn from Dr. Thwaites that in the Botanic Garden at Peradeniya, in Ceylon, there are plants of *hevea* of about 30 feet high, and that these are of the same age as the plants here, the highest of which is barely 6 feet in height.'"

JAMAICA.—Mr. Jenman reported:—"I regret to say that there are only two plants of the Para rubber in the garden, one which I brought with me, and which is now a vigorous young tree 10 feet high, the other, the only one saved out of a case of 16 plants sent from Kew Gardens over two years ago, but which unfortunately on its arrival on Kingston, was locked up in the Custom house for over a fortnight to the influence of which, after the voyage all but the one succumbed. The atmospheric conditions of this district appear favourably adapted to the successful cultivation of the Para rubber."

ZANZIBAR.—Dr. Kirk states:—"The Para rubber is a less quick grower than the Ceara, and does not branch. It is 10 feet high."

Like India-rubber, Liberian coffee, about which so much was written and expected a few years since from its introduction and acclimatisation into many of the British Colonies, has received a considerable amount of attention in the present report. In Burmah, it is said to be thriving and showing signs of flowering, so that it is hoped some opinion of the economic value of the coffee may soon be known.

From Dominica, the late Dr. Imray wrote as follows:—

"I am glad to say that the Liberian coffee cultivation may now be fairly considered as established in this island. The fine, healthy, luxuriant trees on my small plantation, with a crop of berries on many of them, afford sufficient evidence of the climate being congenial to the plant. The cultivation is successful, and only awaits extension by others taking it up. I have several thousand seedlings planted out in the open, and thriving well. I lost a good many seedlings, however, by putting them out when too small. To ensure their rooting they should be pretty well grown before they are transferred to the field. Protection of some kind or other is also advisable at first, as well from the scorching rays of the mid-day sun as from strong winds. When fairly rooted and growing, the plants are hardy enough, and will bear a good deal of exposure and neglect."

Dr. Imray further remarks on the coffee-leaf disease of Dominica (*Cemiostoma coffeelium*), which had succumbed in clearing off the old *Coffea Arabica* plants, but which it was hoped would not find a resting place on the new plants, that it really had attacked the plants in their very young state, and only on the cotyledonary leaves. The leaves were cleared by killing the larvæ, and brushing off the chrysalis wherever it appeared; after this the seedlings steadily increased in size, throwing out fresh leaves, after which most of them were planted out in the field, and were thriving well, with not a speck of the blight on them. Dr. Imray says:—

"This, however, is not the only attempt the insect has made to gain a footing on the Liberian coffee. On carefully examining the large trees some six or eight months ago, a few leaves were found where the insect

really had established itself, but in a very feeble manner. Some of the larvæ were lively enough, but others small and weak, and the skeletons, if I may so speak of others that had died, were found in the brown patches of the leaf, when the upper and under cuticle were separated. Very few cocoons were observed, and these were smaller than usual."

This report from Dominica, which is given *in extenso* in the Kew report, concludes with advice as to the absolute necessity of protecting the seedlings from the ravages of the white fly, without which protection very few of the plants will be saved.

In Jamaica it seems there is a great demand amongst planters for this kind of coffee, but attempts on the part of private persons to import either plants or seeds have failed. The plants, however, in the Jamaica Botanic Garden, have ripened their seeds, which have been sown to increase the stock.

From Seychelles. Mr. E. S. Salmon, the Chief Commissioner, writes:—"About 150 plants of Liberian coffee—mostly raised from seed you sent—have been planted at Mahe Island, at elevations varying from the shore to 1,500 feet above sea-level. It comes best, apparently so far, in the open without shade. One plant at an elevation of about 300 feet, without any shade and close to a granite rock giving out considerable heat, has about 100 strong looking flowers on it. This plant is 18 months old."

From Singapore:—

Mr. Murton reports:—"The Arabian coffee here is severely attacked by the disease *(Hemileia vastatrix)*, which has destroyed all hopes of our being able to supply seeds for planters in the Peninsula. The Liberian coffee has not yet shewn any signs of being attacked, although some Perak planters have been scared by yellow blotches on the younger parts of the branches." (They appear to have no connection with the disease.) "The species is evidently very impatient of deficient drainage. The plants raised from seeds received from Kew in May, 1878, are now blooming profusely. Eight hundred fruits from our plants have been sent to Government Hill, Penang, and 500 sent to Perak. Very favourable reports have been received from the Native States regarding the progress of the plants of this species there, and there can now be no doubt that the Liberian coffee has found a congenial home in the Malayan Peninsula and adjacent islands, and its future propagation may now be left to planters."

In Queensland, Liberian coffee is said to have become thoroughly established on the Herbert river, where it promises to attain complete success; while from Zanzibar the plants are reported to be in flower.

THE RECENT PLOUGHING MATCH.

MR. W. R. ROBERTSON, M. R. A. C., Superintendent, Government Farms, has submitted to the Board of Revenue. Mr. Benson's report on the ploughing matches recently held near Madras. The general arrangements of the competitions in the field were carried out by him and afforded general satisfaction. Mr. Robinson remarks:—"The match, which is an annual one, has hitherto been held on land belonging to the Farm at Saidapet, but at the time when it was thought desirable to hold the match, there was no suitable land available at the Farm. The land was well suited for showing the working capabilities of the ordinary and improved ploughs. An opinion was expressed by some of the visitors that the work to be done was too severe for the capabalities of native ploughs; but such land has not unfrequently to be ploughed, by these ploughs; however, instead of endeavouring to produce the necessary degree of tilth by one operation of the plough the ryot is content if, in dealing with such land, he can effect the tillage required by half a dozen ploughings. It is in the marked superiority of its work, and the low cost at which this is effected that the improved plough excels to greatly that in ordinary use, it has been contended that to economize the time of the ryot is a matter scarcely worth consideration, but such reasoners lose sight of the importance of *expediting tillage operations* in ordinary seasons in this country, when even a day's delay in getting in the seed may cause a difference of 30 per cent. in the yield of the crop. And it must be remembered that during the past twenty years, the price of labor has increased fully 30 per cent. and that therefore even though a ryot may farm on such a small scale as not to require the aid of employed labor, his own labour is nevertheless of greater market value, for such men not unfrequently supplement their form of earnings by the hire they obtain for their own labor. It will be observed that the country ploughs did not penetrate the ground to a greater depth than about 3 inches, while the improved ploughs, the draught of which was very little greater, worked the soil on the average to a depth of about 4½ inches The section of the furrow made by a country plough is a triangle with the apex downward, while that made by the improved plough is a rectangle. Assuming that the furrow of a country plough was 4 inches wide at the top and 2 inches at the bottom, in ploughing a mile the plough would move only about 12 cubic yards of earth, and this be it remembered is only stirred and loosened after the manner of a cultivator, and not raised and inverted. In an ordinary day's work, the country plough would probably travel 16 miles, loosening and stirring only about 196 cubic yards. The improved plough, working to the depth of 4½ inches, would turn a furrow 8 inches wide, the section of which would measure 36 square inches against 9 square inches, the area of the furrow-section of the country plough; while in a mile the improved plough would turn over 49 cubic yards of earth, or in a day's work of 12 miles 587 cubic yards; thus performing as much work as three country ploughs. In these calculations I have made an allowance for time wasted at the headlands. Ryots, therefore, whose holdings are above 50 acres in extent could readily obtain the means required for purchasing an improved plough or ploughs by selling one or more of the pairs of cattle the services of which the adoption of the improved plough would enable the ryot to dispense with. The extra cost attending the employment of the improved plough would be met by the lesser expenditure on labor and cattle-keep from fewer labourers and cattle being required than when the holding is cultivated entirely by country ploughs. It is a matter of importance, I think, that I should point out that six of the improved ploughs engaged in the match have been regularly at work for more than twelve years, and are now almost as good as when they were purchased. The *durability* of these ploughs should be taken into account when their comparative high cost is considered."—*Madras Mail.*

MANILLA HEMP.

MR. LIOTARD, of the Agricultural Department of the Government of India, has this year (1880) reported on the materials in India suitable for the manufacture of paper. Several of the fibre-yielding plants are mentioned by him and, amongst others, various species of the genus *Musa*, of the plantain or banana tribe, many of which have been grown in the East Indies from the most remote times. At pages 54 to 58 he describes the introduction, in February 1858, of the Manilla hemp plant, direct from the Philippines, into the Madras districts, by Colonel (now Sir George) Balfour. Nevertheless, the Import Trade Returns of the United Kingdom show a large and continually increasing delivery of hemp from the Philippine Islands, now averaging yearly about 20,000 tons, valued about half a million sterling I have ascertained from the London Produce Brokers, through Dr. Birdwood of the India Office, that this imported article is the true Manilla hemp from the *Musa textilis*, that the bulk of it is delivered in London, where it is made up into cordage and ropes for ships, especially for yachts running rigging, being very light, strong, and clean, and also for clothes lines.

Year.		Cwt.	£
1877	..	382,814	498,069
1878	..	421,160	551,856
1879	..	337,687	434,087

But there is no doubt that the Manilla hemp plant, *Musa textilis*, grows as well in British India as other species of the plantain or banana genus, and that British India could, in a couple of years, supply the London market with all that it could take of Manilla hemp fibre. The prospect of benefiting British India by creating an export trade from it of the extent and value above indicated might well incite to considerable efforts to attain success. In 1861 to 1863 the Madras Revenue Board made continuous efforts* to secure the naturalisation of the plants which Colonel Balfour had introduced; but their efforts seem to have been effectual only in the Wynaad,* from which, by 1877, the Conservator of Forests replied that the Philippine variety had been introduced on several of the coffee estates where it grows remarkably well, and no doubt is felt there as to the value of its fibre. The attention of of the Boards and Commissioners of Revenue and of the Agri-Horticultural Societies might be redirected to this plant.

EDWARD BALFOUR, SURGEON-GENERAL.

2, Oxford-square, Hyde-park,
London, 15th October 1880.

BRAZILIAN COMMERCE IN 1880.

THE *Journal do Commercio*, which undoubtedly stands at the head of the Brazilian Press, in its issue of January 9th, published (as has long been its custom) a voluminous retrospect for the preceding year. As illustrating the growing importance of the mercantile, agricultural, and industrial movements of progress in the great South American Empire, we will place some of the more significant facts and figures marshalled by our able contemporary and very admirably summarised in a special supplement of the *Anglo-Brasilian Times*, before the readers of our own journal.

The agricultural interests of Brazil,—the broad and stable basis of its national prosperity—has naturally received perferential consideration. Indeed, the prospects of agriculture in Brasil is at present a subject of serious discussion. The actual situation has given rise to a feeling of anxiety, in some minds amounting to positive apprehension. By a noble effort, the Brazilian people have struck a mortal blow at the institution of slavery, and in the course of a few years servile labour must cease to be available for agriculture. In view of this imminent change in the labour conditions of the country it is of course necessary, more particularly on the part of the public authorities, to adopt measures of timely precaution. It is the duty of the Government to provide against any evils that might ensue from a sudden cessation of slave labour before its substitution by free labour has been secured; and as we have every reason to believe, Brazilian statesmen are fully awake to the requirements of the situation, we may hope that they will be prepared to meet the demands of a proximate future. "Trade," remarks the *Jornal do Commercio*, alluding to this subject, "is anxiously awaiting the results of individual initiative and of the energetic action of the public powers, because the development of commercial business is intimately bound up with the development of agriculture. Without looking upon Brazil as essentially agricultural, we must acknowledge that agriculture, or coffee growing, will for many years yet form the fundamental basis of our commerce.

As a producer of coffee indeed Brazil occupies the first place; no other country, in this respect, coming within what may be called "measurable distance" of the Empire. The following figures, showing the comparative production of coffee in 1855 and in 1878 is interesting. They are derived from a German source:—

		1855.	1878.	
Brazil ...	...	168,400,000	225,500,000	Kilog.
Dutch possessions	...	71,832,000	91,404,000	,,
West Indies ...	...	29,300,000	41,800,000	,,
Ceylon ...	...	28,315,000	53,422,400	,,
South Africa ...	...	22,815,000	35,890,000	,,
Arabia ...	...	6,176,000	2,779,200	,,
Africa ...	...	4,000,000	4,000,000	,,
Central America	...	3,500,000	32,500,000	,,
Philippines ...	...	1,858,720	3,396,800	,,
Oceania ...	...	—	150,000	,,
		330,151,980	490,346,200*	

With regard to exports, we find the following:—

It will be seen from this statement that Brazil sends to market nearly half (49·1 per cent.) of the entire coffee production of the world, but it may also be observed that in several of the countries abovenamed a notable development has evidently taken place since 1855. In this sense the most remarkable example is Central America, whose production in 1878 was 32,500,000 kilogs., against no more than 3,500,000 kilogs, in 1855. Thus, though the Brazilian supremacy is indisputable, the planters of Brazil will do well to remember that they cannot afford to neglect any means of maintaining the honourable position they now hold in the coffee markets of Europe and the United States. They have of late been favoured with abundant crops, that of 1878-79 having been 3,705,930 sacks of 60 kilogrammes, and that of 1879-80 about 2,909,038 sacks, whilst, on account of that of 1880-81, for the first six months ending December last, 2,337,047 sacks had already been exported. With regard to the next crop our contemporary states:—

* This estimate is good deal below the mark for the world's production—see our Handbook.—Ed., C. O.

"We now know that the flattering hopes aroused by the first florescence have not been realised; still, though the old trees may not give all they promised, the new trees are affording more than was expected, and our information leads us to estimate the next crop at 3,000,000 sacks."

We concur with the *Jornal do Commercio* in believing that the agriculture of Brazil very materially depends, for its continued and permanent development, on the opening up of cheaper and more rapid means of communication from the interior to the seaboard ports, but it is only fair to add that the Imperial Government has, in this direction, done all that its revenue resources would permit, and has never failed to give legitimate countenance and support to every suitable enterprise calculated to stimulate into productive activity the vast territories still devoid of locomotive or other adequate transit facilities. The establishment of hypothecary banks, for the assistance of agricultural industry, is at present a topic of earnest controversy in Rio de Janeiro. Presumably, such institutions might be advantageous in promoting agricultural effort, but it is questionable whether, as is proposed, the Brazilian Government ought to grant a guarantee of interest on the capital engaged.

The year 1880 was not favourable to coffee exportation. The movement was always irregular, some days of great activity being followed at once by long periods of paralysation. The European markets remained apathetic during the first half-year, and the prices were constantly low there, whilst in the United States the presence of large cargoes, presumed to be for account of the Brazilian Government, kept speculators away. Here the holders and the buyers found agreement difficult, as the latter could not go above certain limits in accordance with the situation of the markets the shipments were for, whilst the sackers were unwilling to sacrifice the article, by selling at a low price, and made the greatest efforts to sustain their pretensions In the last months of the year, when coffee fell considerably in the American markets, some New York and Boston merchants, unable to meet their losses thereby, suspended payments. But the case did not produce the impression feared here and the fortnight in which the news of the failure came was that of greatest sale here.

In tobacco the year 1880 was unprofitable, if not, indeed, one of the losses and liquidations for all the classes depending on the manufacture of Minas tobacco. The low prices which prevailed almost unchanged throughout the year, despite a considerable decrease in the harvest, was attributed by the interested parties to the perturbation produced in commercial relations by the new taxes. But, whilst we acknowledge that the taxes contributed to the evils pointed out, we believe that the principal cause of the decline in prices to the point of being unremunerative consisted in the narrowness of the circle of our foreign customers. And thus the three years of abundant crops prevented the expected reaction after the suppression of the imperial taxes, by permitting the supply to exceed the consumption.

The liabilities of the Empire on December 31st, 1880, were about £70,000,000.

On the whole, the commercial record of Brazil for 1880 is not unfavourable, and presents many features of encouragement for the future.—*South American Journal.*

AN IMPROVED KAISARI PLOUGH.

THE first time I saw one of these implements was in January last, when it was tried in the Government garden, there seemed to be two defects in it. I: The beam was too short. II. The angle the beam made with the handle was too obtuse. At the suggestion of the Deputy Commissioner W. Coldstream, Esq., C.S., defect No. II. was to a great extent modified. A fresh hole was drilled in the handle about four inches lower down. At the second trial better results were obtained, the plough did not wabble or evince such a strong tendency to get out of the ground, and turned up a furrow much deeper than anything the native plough could show, but at the same time there was still a chance of laming the bullocks by running the pointed "share" into their heels—moreover the rope which ran through the eye or hook at the end of the beam and terminated in the yoke, had to be tolerably long, or else the upward strain drew the plough share out of the ground. Here again in remedying one defect we encountered another—the length of rope was such that practically the bullocks were out of control—and for this defect there was but one remedy, that being, to discard the short beam once and for all, and put in a beam which should be fastened with a loop and pin into the yokes on the oxen's necks.

This was done, and the results obtained most gratifying. A deep furrow and complete inversion of the soil was effected, the driver or ploughman had his animals completely under control, he could twist their tails to his heart's content, the motion was very even and regular, and at the same time, there was no fear except in unskilful hands of the animals being tamed by the sharp-pointed share.

The same plough was tried afterwards on rough ground which had never been ploughed within the memory of man, it answered very well, nothing could have done better. A native plough was tried on the same piece of land, and was nowhere. Natives like it, *ordinary* cattle costing Rs. 50 a pair, will drag it with ease, and under *ordinary* circumstances will give a furrow about six inches deep, though by the exercise of considerable physical force the ploughman *can* loosen the soil to a depth of 8" or 9."

There is every season to hope that the natives about here will take to them in time, as they admit their superior performance and consequent economy.

Another plough was made up here.

Wooden *vertical* handle, wooden beam, bolted to handle, and capable of being regulated to suit any sized bullocks from the largest to the smallest, to enable it to do this, a wrought iron "skife" is bolted to the angle iron slade, through this skife are drilled four or five holes, and into any one of these holes the beam can be adjusted to suit the size of the oxen.

Slade is of angle iron 2½"×2 ½"×½." Share is of steel breast of ¼ plate worked out to the proper shape, at its lower end rivetted to the slade and at its upper end secured to it by a strip of plate 1"×½." rivetted mid way between handle and skife to the vertical flange. It is somewhat heavier than the "kaisari," but in my humble opinion more effective. On Thursday last I gave it what may fairly be considered a good test, a field of old canes or more strictly speaking young ratoons had to be ploughed up, work was commenced in the morning, by evening one beegah of land had been ploughed. I should add, however, that the bullocks had been to the slaughter house in the morning for bones and had made two trips before being set to the plough. The old roots were cut through and torn clean out of the soil bringing out clods of earth weighing about 20 to 30lbs. Crowds of natives assembled to see the *tamasha*, and admitted that with their implements they would have had to plough up their soil *six to seven times* before they could have produced the same effect.

In carrying out the modifications of the kaisar plough as detailed above, Messrs. Ransomes, Sims, and Head, Primitive Plough, P. I. L., *vide* their catalogue No. 1420E, page 28, was taken as a standard, their ploughs weigh as much as 98lbs which is very heavy, and cost in their shops at Ipswich £1-10*s*, extra "shares" cost 11 shillings per dozen.

The kaisari and its modification do not cost more than Rs. 4 to Rs. 4-8, and each "share" costs 2 annas, or Rs. 1-5 per dozen.

There is one advantage about these ploughs, *viz*: that should you wish to prepare that soil before the rains, say early in June, these ploughs will turn up its surface however baked, and hard it may be. Whereas the native plough cannot do anything of the kind, in fact the chances are it would break to pieces before you had done one kanal of land—(1 kanal 1/10 of an acre)

A light though at the same time very effective ridging plough might be made on the principle of the kaisari by substituting a ridging share for the ordinary triangular piece now made up, and constructing two moveable breasts to be adjusted to any angle. For turnips, maize and wheat, an implement of this sort would be founed very desirable.

THE VALUE OF SAWDUST MANURE.

I AM glad to see that Mr. Westland has put the question as to the value of sawdust manure. The same thought had occurred to me more than 12 months ago in regard to its usefulness or otherwise for horticultural purposes. My experience here, amidst so much market-garden farming, had previously fully established its reputation as a highly-fertilising medium for fields and field-grown crops. As, however, from some cases not yet explained this material did not appear to be so popular as it should be, and knowing its value from personal observations made during my frequent visits to farmers around, I determined upon having a wagon load, and to test it for myself, as I am so frequently asked questions in regard to a manure readily obtainable for the use of amateurs. The load which I got came direct from the London General Omnibus Company's yard. It was quite fresh, and was very hot from fermentation. I had it shot in a convenient place for a day or two, and then began to test it. It would take up too much of your space for me to give in detail what I consider to be the complete success of my trial of this material with all kinds of crop, not excepting grass sward, vegetables, fruits, &c., especially raspberries, the canes upon which are now half as large again as they were previous to its use. I will give but one fact in regard to it, which I think speaks loudly in its praise. At the time I commenced to test it I had living in the greenhouse two dozen each of hyacinths, narcissi, and tulips, which had not yet been planted, though it was getting late in the season for so doing. To test this material I had a large box filled entirely with the material, and without even the addition of soil of any kind. The bulbs were then pressed firmly into it. First a row of dwarf tulips, then a row of tournesols, another of hyacinths, and at the back two of polyanthus narcissi. These made a wonderful start. The roots seemed to run rapidly into the sawdust, and fine breaks were made. When the leaves with flower spikes were some 4in. long, I had an intention to pot them off into very small pots for our Whitsuntide church decoration. Imagine my surprise when I found the roots so matted together that I could not separate the bulbs in any other way than by cutting them out in squares about the size of the bulbs. I tried to pull some up, but the stalks, flowers, and all, parted from the bulbs rather than lose their hold on this free, open material. The half which I left to bloom undisturbed in the box garden gave exceptionally fine spikes, &c. No greater proof is wanting that this manure is perfectly innocuous, and most valuable. I think it has received a most undeserved bad name from the fact that "sawdust manure" was at one time only to be had at the Zoological Gardens. Doubtless this mixture was too powerful for direct application to any vegetable growth. Those who now use it say little for or against it, because, as it is got very cheaply, it is to their interest to do so. It is in great demand in the neighbourhood of Manchester.—WILLIAM EARLEY.—*Gardeners' Chronicle.*

THE CONSUMPTION OF CAOUTCHOUC, OR INDIA-RUBBER.

FROM the report of Messrs. Hecht, Levis, and Kahn, on the trade in India rubber during the year just passed, we gather some idea of the importance of this commodity from a commercial point of view. It seems that larger supplies of most kinds of rubber came into the markets than in the previous year, and there was a largely increased consumption, especially in the United States of America. High prices ruled throughout the year, fine Para realising as high a price in April last, as 3*s* 9*d*. per lb. The total exports from Para to all parts are estimated at 8,500 tons, being an increase of 660 tons against 1879. The imports into London and Liverpool were 3,768 tons against 4,651 tons in 1879, showing a falling off 883 tons. The United States have therefore absorbed 1,400 tons more than in the past year.

INFLUENCE OF THE INTENSITY OF LIGHT ON THE DECOMPOSITION OF CARBONIC ACID IN PLANTS.—The last number of the *Annales des Sciences Naturelles* to hand contains a translation of an article on this subject, which originally appeared in a Russian publication. We extract the summary:—1. For a whole series of plants there is a maximum intensity of light favourable to the decomposition of carbonic acid: and if this maximum is exceeded, the plant never decomposes more carbonic acid, though in some cases the energy of decomposition is diminished under an excess of light. 2. A jet of gas equal to 50 candles is able, if the dark rays be carefully absorbed, to cause an extraordinary decomposition of carbonic acid, the quantity of oxygen liberated being in relation to that obtained under the influence of the sun as three to one. This indicates the existence of a favourable maximum intensity of light. 3. The existence of a maximum is probably intimately connected

with the changes of position and size of the grains of chlorophyll. 4. This maximum is of the utmost importance in studying the influence of the coloured rays on the decomposition of carbonic acid, and it also partly explains the contradictory opinions entertained by different writers.

PERPETUAL FLOWERING CARNATIONS.—Year by year the number of growers of these beautiful sweet-scented winter-flowering plants seems to increase, and those who do grow them can seldom get enough. It is also very satisfactory to know that they are easily raised from seeds. Some time ago it was recorded that Mr. Charles Turner of Slough, sowed some seeds in January, and flowered the plants in the autumn following. The variety from which the seeds were saved was the rather recently introduced variety, A. Alegatière. The habits of this variety is all that can be desired when dwarf bushy plants are in request, and its bright scarlet flowers are very showy. It is is not likely that any light-coloured flowers would be raised from this variety without crossing them, but it would be well to do this; it would not be easy to say what would be the result of crossing with dwarf white or flesh-coloured flowers. Although these dwarf forms are well adapted for some purposes, the height of many varieties is not objectionable. Of these may be named King of the Belgians, a fine rich rose; La Belle, white; Miss Jolliffe, pale pink; Rose Perfection, Scarlet, Defiance, and one or two others. There seems to be a craving for dwarf plants of everything, but in many cases this does not improve them, and sometimes it is the other way. The moderately tall forms work well in amongst other plants, and are at all times effective.

CONCERNING THE PLOUGH.

THE journal of the Anthropological Institute lately contained an interesting paper by Mr. E. B. Tylor, on the origin of the plough and wheel carriage. We propose to give our readers a sketch of several of the earlier stages by which the former of these useful implements has arrived at its present state of perfection. To some of Mr. Tylor's readers, who have never left the shores of England, it may have seemed that several of his conclusions were rather conjectural. From the pointed stick to the steam or electric plough, there is certainly a vast gulf, which requires a considerable effort of unaided imagination to bridge over. As a matter of fact, however, the imagination is not left without the help of solid facts. Those who have travelled among primitive peoples, and in Eastern lands, will have met with numerous intermediate forms actually in use at the present day. It is thus that a knowledge of the different stages in civilization of the men now living, affords us the means of ascertaining the steps by which the race has progressed in the past.

The primitive agricultural implement is the pointed stick. Here we seem to have the original whence have sprung, during the long course of ages, and by many curious modifications, all the principal implements of modern agriculture. The spade, the plough, the harrow, the roller, the sowing machine, can all be traced back to one and the same lowly origin. The natural laziness or intertia of human nature is so strong that we can well conceive how the beginnings of agricultural life might have been indefinitely prolonged had the primitive man been compelled first to invent an implement for the purpose. This, however, he had not to do; for the pointed stick had already been his daily companion, for probably thousands of years before he began to till the ground. It was both a weapon and an implement. With it he was wont "to dig up eatable roots, knock down fruits or dry branches for fuel, and even, if used were, break an enemy's head." In Lichtenstein's time the Kaffirs used the assagai or spear, and the kirri, both as weapons and as implements of husbandry: the kirri being a stick about two and-a-half feet long with a knob at one end, which served the double purpose of a club in war, and a dibble and clod-breaker in peace. The pointed stick, either by itself or along with more improved implements, is of amost universal use at the present day among those semi-savage tribes who have made the first rude beginnings in agriculture. It is in use among the Veddahs of Ceylon and the Hill Tribes of India generally, in New Guinea, Fiji, and the South Sea islands, and to a less extent in Africa and America. It is usually assumed that the spade is the predecessor of the plough; which is doubtless true if we look at their actual introduction into modern agriculture. But this must not be supposed to mean that the spade was one of the steps by means of which men came a length to invent the plough. For, as Mr. Tylor points out, it does not appear as it the plough was developed from the digging-stick by passing through the transition stages of the spade. Rather it would seem as if the plough and spade were divergent branches from the same parent. Like certain variations in the vegetable and animal kingdoms, which soon reach the highest devolpment of which they are capable, the spade would appear to have undergone at a comparatively early period almost all the improvement of which it was susceptible. The plough, on the other hand, when it diverged from the original digging-stick in long bye-gone ages, and before the dawn of history entered upon a career of progressive improvement, the end of which we do not even yet see. Let us recall a few of the intermediate stages.

The primitive pointed stick, implement, and weapon in one, seems to have undergone two modifications; its point being in the one case flattened like a paddle, and in the other bent. The former diverged in the direction of the spade, the latter in that of the hoe and the plough. Here again we are not to suppose that primitive man set himself deliberately to invent an implement which would combine the advantages of a digging stick and a hoe. Nature herself has filled the forest with sticks of every variety of shape, and a lucky accident suggests to the savage's uninventive mind how they may be used to satisfy his few and simple wants. Mr. Tylor gives figures of several implements which illustrate the early forms of the digging-stick. One of these is a hoe or pick from New Zealand—a pointed stick curved so as to resemble a side view of the Indian mamoty, which by the way has more affinity to the hoe, or pick, than to the English spade. The next figure is that of an implement from an opposite quarter of the globe. In Sweden tradition points to the use of the hack in tilling the soil and "within a generation there was still to be seen in use on forest farms the 'hack' itself, made of a stake of spruce-fir, with at the lower end a stout projecting branch cut short and pointed." When sticks with the requisite bend or projecting branch could not be found, invention would show itself in fastening a pointed bit of wood at the proper angle to a handle, as was done by the North American Indians. The next and a real step in advance is seen in the substitution of something harden than wood for the pointed part. Thus we find the shoulder-blade of a buffalo, or elk, fixed to a handle in use among the Mandans of North America; elsewhere a piece of shell takes the place of bone. All this prepares the way for the introduction of metal blades or points, which at once puts us in the way leading to the most improved forms of the modern hoe.

A word may be added respecting the prevalence of the hoe. It may be regarded as being in a special manner the agricultural implement of the African continent, appearing in a variety of forms, such as the simple hoe, the pick, and the mattock or mamoty. It is used by the tribes on the North-Eastern frontier of India, and occasionally by the more settled races of North and South America. Few who have intelligently studied the structure of Indian ploughs, and seen them at work, will question Mr. Tylor's conclusion "that the primitive plough was a hoe dragged through the ground to form a continuous furrow." Divest it of the stumpy handle by which the ploughman keeps the point in the ground and it is easy to see that the native plough is a huge hoe or pick, the pole by which it is dragged representing the original handle of the hoe. This opinion is borne out by historical and pre-historical research as well as by the pictures on ancient monuments. In Sumatra, says Marsden," the soil is either turned with a wooden instrument between a hoe and a pickaxe, or with a plough, of which they use two kinds; their own, drawn by one buffalo, extremely simple, and wooden share of it doing little more than scratch the ground to the depth of six inches; and one they have borrowed from the Chinese, drawn either with one or two buffaloes . . . turning the soil over as it passes, and making a narrow furrow." In Sweden the wooden hack already described "was followed by a heavier wooden implement of similar shape which was dragged by hand, making small furrows; this 'furrow crook' is still used for sowing. Afterwards was introduced the 'plough-crook,' made in two pieces, the share with the handle, and the pole for drawing. The share was afterwards shod with a three-cornered iron bill, but the implement was long drawn by hand, till eventually it came to be drawn by mares or cows." It is interesting to find our theory supported by facts drawn from countries so far apart, and so dissimilar in character as Sumatra and Sweden. In additon to the hoe and the plough, both countries possess an intermediate form of implement (part hoe, part plough), which helps us to understand how the the former has by gradual modifications been tranformed into the latter. Mr. Tylor calls attention to the parallelism between these transformations in comparatively modern Sweden and what took place in ancient Egypt.

The study of Egyptian monuments cannot leave a doubt in the mind that the hoe and the plough are the same implement, modified in the former case to be worked like a pick, and in the latter to be dragged by men with ropes. Mr. Tylor gives a copy of one of these ploughing scenes where "the man who follows the plough to break up the clods is working whith ordinary Egyptian hoe remarkable for its carved wooden blade longer than the handle, and prevented from coming abroad by the cord attaching the blade to the handle half way down. This peculiar implement, with its cord to hold it together, re-appears on a larger scale in the plough itself, where the straight stick is lengthened to form the pole by which the oxen draw it, and a pair of handles are added by which the ploughman keeps down and guides the plough." Italian monuments present a variety of form of the plough, all in suggesting that they are merely enlarged and transformed hoes. All of them have the long pole more or less straight for dragging them, and the share fastened to it at varying angles. Some have a handle for the ploughmun to hold by, others not; while others again are provided with both a handle and a projection for the ploughman's foot. Along with these more primitive forms there existed in Pliny's time ploughs resembling our modern plough, and provided with coulter and wheels. This fact is interesting as showing how inferior forms of implements may exist for centuries side by side with those of superior construction. By those who expect great and sudden results from the establishment of model farms and agricultural colleges in India such a fact ought to be taken to heart. We are apt to assume that the native ryot is one of the most singular of beings, because he persistently adheres to his time-honoured plough, notwithstanding that superior implements are forced on his notice. But we expect more from the ryot than we have any right to look for. If the primitive plough could hold its own for centuries in the ancient world against all comers, what right have we to expect, as we often do, that the Hindu ryot is in the course of a single generation to abandon his venerable plough (enlarged and transformed 'ee though it be), for the more finished productions of Saidapet? In the end, no doubt, the native plough must succumb to the modern implement, but this can only be by a process so very slow as the lead ardent reformers to despair of agricutural future of India.—*Madras Mail.*

THE *SURGUOJA* PLANT.

From F. B. Peacock, Esq., Officiating Commissioner of the Presidency Division,—to the Secretary to the Government of Bengal, Financial Department.

REFERRING to your letter No. 241, dated 1st December, with enclosure, I have the honour to submit, for the information of his Honor the Lieutenant-Governor, the following report on the cultivation of *surguoja* plant in the district of Nuddea.

2. This plant is cultivated in the sub-divisions of Chooadanga, Jhenidah, and Meherpore, and bears different names in the different sub-divisions. In Meherpore the Hindoos call it *surgooja* and the Mahomedans *gunja*. In Jhenidah it is known as the *guji* or *surguji*, while *sukargoojari* is the name given to it in Chooadanga, which is apparently a corruption of the word *surgooja*. Mahomedans from the chief element of the population of this district, and as they have a prejudice to pronounce the word *sukar* (swine), they omit the first two syllables and call the plant *goojari*.

3. This plant is not an indigenous product of the Nuddea or any adjacent district, but is reported to have been brought originally from Chota Nagpore, where it is said to be in extensive cultivation. The Sub-Divisional Officer of Chooadanga reports that the cultivation of *surgooja* was introduced into the Nuddea district about 30 years ago by one Miboo Boona of Barribonha in thana Gangani of the Meherpore sub-division, and has gradually extended until, in the sub-division of Chooadanga alone, it is estimated to cover an area of 4,000 beeghas. The Sub-Divisional Officer of Jhenidah, a sub-division of Jessore, writes to say that the plant has been known in his sub-division for many years.

4. The plant is generally grown as a second crop following rice, tolerably high lands being preferable for its cultivation. The seed is sown in October, three seers to a beegha, and the plant flowers in December. In January the seed-pods form and mature, and by the end of the month, or early in February, the plant is cut and the seeds gathered. The method of cultivation is comparatively simple. Two ploughings only are given before the seed is sown, and no weeding is needed.

5. The cost of cultivation amounts to about Rs. 2 per bigha:—

	Rs.	A.	P.
Ploughing and sowing	1	5	0
Cutting and thrashing	0	9	0
Seed from mahajun	0	2	0
	2	0	0

The outturn from a bigha of land is from 2 to 3 maunds of seed, or on the average 2½ maunds. The value of the seed is Rs. 4 per maund. Thus an average crop gives a profit to the ryot of about Rs. 8 per bigha, from which, however, has to be deducted half the rent of the land, the crop being a second crop.

6. The Small Cause Court Judge of Chooadanga in his report to his Honor, which forms the enclosure of your letter under reference, stated that a maund of *surgooja* seed yielded about 14½ seers of oil. This proportion is considered by the Sub-Divisional Officers of Jhenidah and Chooadanga as rather high. The former puts it at 10 seers, and the latter at 13 seers 2 chittacks. One maund of mustard yields about 14 seers I chittack of oil, but this difference is compensated by the fact that the *surgooja* is a more certain and easily grown crop, and its yield for the same area larger.

7. The *surgooja* seed is rarely used unmixed in the preparation of oil, but generally in combination with mustard and linseed, in the proportion of one to four. The oil expressed from the *surgooja* is thicker and less palatable, and is used chiefly to adulterate lamp oil. Some of the poorer classes used the adulterated oil in the preparation of curries, but the flavour is not liked, and all who can afford it use pure mustard oil, keeping the mixed oil for lighting purposes only.

VANILLA.

THE genus vanilla, says Mr. G. W. Septimus Piesse, is indigenous to Peru, Brazil, and Mexico, and some of the species have been successfully cultivated in the West India Islands, Ceylon, and Mauritius. From the last-named, wonderful fine specimens were sent to our inter-colonial exhibition of 1862, for which the jurors awarded a gold medal.

The vanilla will produce saleable pods the third or fourth year after propagation, and they may then be gathered annually in September, in increasing quantities, for thirty or even forty years. Two good specimens of the plant may be seen in the Orchid House at Kew.

When the pods are gathered, which should be done before they are quite ripe, it is most important that they be properly cured, otherwise they rapidly become mouldy, and lose their scent. Parcels in this condition may often be found in the Mincing-lane drug auctions. The curing of the pods is best effected by drying them in a moderate heat, pressing them with the thumb and finger from end to end and then brushing them over with an oil that does not itself become rancid, such as that of cocoa or cashew nut. It is at the apex of the pod that the mouldy parasite first appears, the pods then quickly become soft and flabby, or dry and chippy. On the other hand, when vanilla pods are in good condition they become covered with an efflorescence of needle-like crystals of vanillic acid; the interior of the bean is then soft, unctuous, and balsamic. These crystals may be sublimed by heat of a sand bath. Few objects are more beautiful than this when viewed by a microscope with the aid of polarised light.

I. F. H. Johnston states that the fruit of this plant when ripe is said to yield from two to six drops of a liquid which has an exquisite odour, and bears the name of "balsam of vanilla." This balsam is, however, never seen in Europe, consequently it has never appeared commercially in the market. The pods are dried in the sun, and afterwards slightly fermented, for the purpose of developing their odour; when fresh, they are said to have no perfume. Physiologically, the fragrance of vanilla acts upon the system as an aromatic stimulant, exhilarating the mental functions, and increasing generally the energy of the animal system. About two centuries ago vanilla may be said to have been unknown in this country; it is, however, stated that Morgan, apothecary to Queen Elizabeth, showed her Majesty a sample, but he knew nothing more about it than that "it was brought from abroad by some Spanish merchants."

A few years back the average importation of this article was about five or six hundredweight, which arrived, from some unknown cause, very irregularly, and as a consequence caused great fluctuations in the price. At the present time the total annual average crop of all the varieties of vanilla from the several countries which produce it may be estimated at 80,000lbs., representing a value of not less than £150,000.

In order to obtain the perfume, or essence, half a pound of the pods are slit from end to end, so as to lay open the interior; then cut them up in lengths of about a quarter of an inch, and put into one gallon of pure alcohol of 60° over proof, and macerated with occasional agitation for about a month, at which time all that is worth extracting will be found in the spirit, which may then be strained off quite clear and bright. It is then suitable as a flavouring agent, or when blended with other scents it makes compound odours or bouquets. Those sold under the titles of clematis, heliotrope, wallflower, &c., mostly contain about one-half of vanilla extract.

The following gives a good

ESSENCE OF WALLFLOWER.

Extract fleur d'orange	...	...	...	1 pint.
" " vanilla	...	...	...	½ "
Esprit de rose	...	...	...	1 "
Extract of orris	...	...	...	½ "
" cassie	...	...	...	½ "
Essential oil of almonds	...	...	...	5 drops.

This should be prepared for two or three weeks prior to putting up for sale.

The odour of heliotrope resembles a mixture of vanilla and almonds, and is well imitated thus:—

EXTRACT OF HELIOTROPE.

Spirituous extract of vanilla	...	...	½ pint.
" " French rose pomatum		...	¼ "
" " orange flower "		...	2 ounces.
" " ambergris "		...	1 ounce.
Essential oil of almonds	...	...	5 drops.

—*Monthly Magazine.*

HOW TO USE BONES AS MANURE.

OF the various ways to make use of bones as manure, crushing to bones dust, or converting them into superphosphate of lime are the two best; and burning to ashes or converting them into charcoal the worst.

The dust can be either harrowed or ploughed in as circumstances warrant.

The superphosphate can be spread broadcast and harrowed in, or, what is better, drilled in with the seed, or with potato sets. It can be made at home with the exercise of a little care, and it will reward the trouble better than burning the bones to ashes, the benefit from which might be much more economically obtained from a few pounds of lime direct, seeing that only a small percentage of lime is all that is got by burning bones; and as for converting them into charcoal, all the goodness or virtue of them is lost, changing them into an imperishable substance of no use whatever.

If all the bones that collect on a farm were systematically preserved, it is astonishing the quantity that accumulates in a year, but which are usually allowed to lie about slovenly and untidy. Sometimes they are spasmodically gathered and dug under a tree in the orchard, but not with that judgment that is displayed in other ways on the farm. Let three or four oblong holes about 18in. deep be dug round a tree, at a distance from the butt equal to the spread of the widest branches. Here probably will be found the extreme rootlets of the tree; if not, try another hole a little nearer; then throw in bones to the depth of 6in. or 8in., and fill up with earth. This method of applying bones to trees will be found of more avail than using them in the form of ashes dug into the surface round the butt, which last method is only serviceable so far as loosening the surface, giving better facilities for the absorption of rain in summer.

It is not generally consider ed that the roots of fruit trees and vines are far below the reach of spade manuring, and consequently the digging in of farm-yard manure is labour absolutely wasted, particularly on ground trenched 18in. or 24in. deep.

ON THE PREPARATION OF TAPIOCA (*MANIHOT UTILISSIMA POHL*) IN THE EAST.

THE granulation or coagulation of various speculent or gummy extracts, has frequently been stated to be brought about, or at least expedited by the addition or instrumentality of plants or parts of plants added thereto.

That the addition of the bruised stems of *Calonyction speciosum* to the milk of the *Castilloa elastica* of Nicaragua brings about the more ready coalescence of the contained India-rubber there seems to be no doubt, the effect being analogous to that of rennet in the case of milk. Dr. Seemann, speaking of the preparation of rubber in this way, adds, "I saw a similar process for thickening sago in Singapore."

In his narrative of the voyage of H. M. S. *Herald*, Dr. Seemann also remarks that in the preparation of Gambier, a piece of wood is dipped into the watery extract, which becomes, by means of this wood, quickly inspissated (*vide* vol. ii., p. 250).

The same remark has also been made as to the cause of the agglutinated measures of tapioca, but with regard to this latter substance and sago, our opinion has always been that the agglutination was caused by part of the starch being changed to dextrine by the application of heat.

A recent traveller in the East thus writes us on the subject: "In the case of Gambier, I only saw a part of its preparation. It was in Malacca near a Gambier, plantation, where I saw two or three Chinese coolies just boiling down the freshly gathered plant in a large shallow iron pan of 'kwali' in the open air. Their stirring apparatus consisted of *two or three* different kinds of wood, and a long handled iron shovel flat in the blade, somewhat of the same shape as that used by bakers. The latter seemed to be the most prized. Either from jealousy, or because the coolies understood little Malay, I could not ascertain whether any *particular* wood was used or prized.

"As to sago, although I took many a journey purposely, I never saw the whole of the preparation from beginning to end. What I did see, however, left me no grounds for the belief that the granulated kind owed its form to the use of any particular wood. Moreover, I was assured by European planters and native operators that various wood were used as stirrers, but none for possessing any particular properties, and that iron stirrers were much perferred.

"As to the preparation of tapioca, I was more fortunate, seeing the whole process from the fresh root stock to the finished product in the process of packing for market.

"Being in Malacca, I ascertained that there were two or three large tapioca plantations some miles up-country, and a friend kindly offered to make arrangements for my visiting them. Travelling in the East, by the way, is no easy matter, and moreover, very costly. Unless one accepts the lumbering springless bullock cart, and is satisfied to spend a night or two in some filthy native hut (if he can find one), he must often employ six horses in relays to travel under thirty miles. In our case, to accomplish a journey of thirty-seven miles, we changed ponies five times; of course three of them were left at various intervals on the outward journey to rest and be used again on our return. Having seen to our provisions and weapons, we started by moonlight, the time being about 4 A.M. daylight, as is the rule in the East, coming suddenly and swiftly about 6 A.M.

"As to our ride and what we saw on the way, I need not dwell on here, suffice it to say that we visited three or four plantations all conducted on the same principles, and it will be sufficient if I describe what I saw of the largest and best.

"The factory which we entered was well and substantially built of stone and brick, and belonged to a wealthy Chinese. We were soon ushered into the owners presence, and received with that courtly ceremony, for which the well-educated celestial is remarkable. Refreshments were quickly served, consisting of tea, 'tigers's milk, *i.e.*, the milk of young cocoanuts with a dash of brandy, various fruits, &c. We had to learn it we had never yet learned, that an Eastern must not be hurried, but at last having really made our host understand that we could not partake of more, we wended our way across a court laid out in real Chinese style with gotesquely cut plants and fountains, and found ourselves in the busy manufactory. Here, above and around us, were endless bands and shaftings, driven by a large horizontal engine of English make, and in charge of a European engineer. The streams of water led hither and thither sounded like some gigantic water-fall, and the natives with but a loin cloth, and that of the scantiest dimensions, with the glowing fires playing on their well oiled bodies, added interest to the scene.

"Taking our station at the far end, we saw droves of Chinese arriving from the fields with baskets slung on poles, and filled with the fresh tapioca root-stocks. These were at once taken by another gang to large tubs fed with a constant stream of water, and the root-stocks thoroughly cleansed from adhering mud. Thus cleansed, they were passed on to a 'paring' table, where the dark outer coat was peeled off, just as one would treat a turnip, and all discoloured or bad parts cut away. Next the cleansed root stocks were passed on to a machine furnished with

knives, and sliced, and then passed on to a crushing machine, by which it was reduced to a pulp. After being thus treated, the pulp was removed in cane baskets to the 'strainers.' These strainers were large wooden frames with calico bottoms, and were filled with pulp from the baskets. Above these strainers were tanks, giving off a powerful stream of water which impinged on the pulp, and by means of the shafting, motion was communicated to the strainers exactly the same as that given to the sieve in hand-sifting.

"As the starch became washed out, it was received into inclined troughs and allowed, whilst in suspension, to run into settling 'vats.' Here, afte well stirring, the starch was allowed to settle, and the now dirty, water, drawn off. Fresh water was next pumped in, and the process repeated two or three times, till the starch became clear and white. In this part of the building, which was on a lower plane than the rest, the smell of hydrocyanic acid was by no means faint. The starch was next drained, and whilst still moist removed to the drying department.

"The machinery I have mentioned occupied the central line of the first half of the building, and on either side next the wall was placed the drying apparatus.

"On the one side tapioca flour was prepared, and on the other the granular forms. The flour was prepared by simply spreading the still damp starch on a long iron table or slab, heated *slightly* by fires underneath, and constantly stirred and turned over with iron shovels till perfectly dry.

"The granulating was done as follows:— There was a long range of "kwallies," or shallow iron pans, standing on ledges of brickwork and slightly tilted forward. A wood fire was under each, so that each operator had a fire and 'kwali' to himself. Taking up a quantity of damp starch it was placed in the 'kwali' stirred constantly with the iron shovel, and the heat being greater than that employed in the simple drying of the flour, the starch soon became agglutinated together by the formation of dextrine. I could not but admire the dexterity with which the operation was performed to a 'turn,' and how well the open fires were managed.

"Such, then, is the operation as seen by me, and when I asked (although a disbeliever) whether the use of any particular wood would bring about the same change, or ever hasten it, I was told no. The only reason wood was occasionally used was because iron was dearer, and no one would use the former who could produce the latter.

"The Chinese and Malays are very superstitious, and their Materia Medica filled with most grotesque things, yet some of our own books of the last century would not yield the palm in absurdity. The wonderful affect of certain woods, &c., finds, too, its parallel in our own 'divining rod,' which, if made of hazel, peeled, cleft, and held in the orthodox way, would, aided by the pixies, discover hidden mines and springs. But to conclude. After seeing all that was to be seen, we found a varied table spread for us, consisting of soups, fish, fowl, curry and rice, pork cooked in twenty different ways—in fact, a regular, mixture of European and Chinese fare. After enjoying our host's kind hospitality we took our leave."—*Ceylon Observer.*

LOSSES WHICH FARMERS MIGHT AVOID.

PROFESSOR WRIGHTSON, writing to the *Squire*, one of the latest additions to our stock of monthlies, says:—

'Every mickle makes a muckle,' is an old Scotch proverb. It means, as readers of the *Squire* know, that a number of trifles, which singly might appear unworthy of attention, may when added together form a very considerable aggregate of loss or of gain. It points in the same direction as our well-known sayings, 'Take care of the pence and the pounds will take care of themselves,' and 'Every little helps, as Jenny Wren said,' &c., &c. In no place more than in the field and farmyard is either proverb applicable.

I proceed to amplify it, by pointing out a few of those numerous ways in which trifling sums are lost in farming. Firstly, attention might be called to the fact that on a large farm money is lying about in all directions Here lies a trough worth three half-crowns, and there is a heap of old iron and other rubbish worth 30s. A visit to the simplest sheds, or even a cursory look along the backs of hedges or behind walls, reveals the presence of implements, logs of wood, old carts with good iron work still clinging to rotten wood, and numerous worn-out or broken tools. A low valuation of these sundries would probably astonish their owner. They might be converted into several shining sovereigns, while at the same time the general tidiness of the farm and buildings would be greatly enhanced. In these times, when farmers are short of the sinews of war, such a source of ready cash certainly ought not to be lost sight of.

In looking around many farms, a source of profit is to be seen which has been long neglected. On the sides of roads, accumulated about the buildings, and by hedges and ditches, are to be found large quantities of rich vegetable mould often covered with grass. This soft black soil is peculiarly rich: it has received constant additions of straw, rubbish, lumber, barn refuse, refuse from heaps of mangel, &c., &c., and it would pay to get it up and cart it on to the neighbouring pastures, and spread it thereon. This is a source of fertility which many farmers never dream of utilising.

A glance at the stock-yards of nineteen farms out of twenty reveals a dribbling loss which might be converted into a profit. Large yards, surrounded with big-roofed, old fashioned buildings, are found shooting their rain-water into the quadrangle. The farmyard manure is literally swamped. It is veritably under water; the cattle stand contentedly enough knee-deep in slush. This may satisfy certain old-fashioned ideas, but it does not meet the requirements of modern farming. A reduction in the size of yards, abundant shed room, and sufficient troughing or spouting to carry off the rain, should be insisted upon by every would-be tenant and granted by every good landlord. It is impossible to carry out a system of high feeding with profit unless premises are made suitable for the preservation of farmyard manure.

A source of profit wilfully neglected by the average farmer is the poultry. He actually thinks this branch beneath his attention, and as in some cases he leaves it to his wife, conceding the profits thereon, we hear that he actually grudges the food which, in the long run, is destined to appear in the shape of ribbons and laces on his wife's person. This is short-sighted policy and mean, we are sure our lady readers will think it to be. The fact is, poultry are coming to the front, and a well regulated poultry yard is a very desirable adjunct to the farm buildings. If poultry are attended to, new blood imported, goods breeds adopted, and the [illegible] kept sweet, they will pay well. If the farmer, then, is too much occupied to look after the hens, perhaps an arrangement might be come to with his wife, by which the funds accruing from the [illegible]

of eggs and chickens should be devoted to more solid and useful functions than that of buying bibs and tuckers.

The feeding of animals is a profitable pursuit, but unless reasonable care is taken a great deal of food is wasted or rendered unpalatable. How often do we see a stupid lout serving pigs, and throwing 10 per cent. of the rich barley-meal porridge on the litter! and a glance into the cattle troughs often shows a disgusting accumulation of fetid matter, which must be injurious to the animals which feed from them.

Hay and straw are wasted every day in ways which a little care would easily prevent. Every straw rick is worth thatching. No large 'cuts' into either hay or straw ricks should be allowed, and care should be taken to prevent loose litter from getting wet and useless.

It must, however, be said, in justification of the farmer, that the crass stupidity of the labourers in this particular is most aggravating. They will not see the importance of taking care of straw, and in this careless state of mind they are encouraged by the traditions of the past, when, as long as straw was trod under foot or got crushed down into some semblance of manure, it was thought a good end for it.

I would also draw attention to the evil consequences of allowing implements to stand out in the fields month after month and year after year. Carts, wagons, rollers, ploughs, troughs, bodkins, and 'tackle' of various kinds are often to be seen exposed to the heat of summer and the rains of winter. No wood work or ironwork will stand such treatment. A very definite depreciation must be recorded at the end of a year in all such cases, and the bill for repairs and replacements must be greatly increased. And the larger and more expensive implements fare but little better. Farmers' portable engines, steam cultivating apparatus, thrashing machines, chaffcutters, horse gears, &c., fare but badly. Clotted with old oil and rust, left unpainted from first to last, insufficiently protected from the weather, worked with but little care or judgment, these implements soon deteriorate in value and do not last out a reasonable time.

ARTIFICIAL POULTRY RAISING.

A PROMINENT dealer in poultry, Mr. H. W. Knapp, of Washington Market, New York, gives a discouraging opinion of the probably success of chicken-raising by artificial means. He said recently when questioned on the subject:—

I went to France to study the matter, for if it can be made to succeed it will make an immense fortune, as it has already done in Paris. I was delighted at what I saw there, and the matter at first sight seemed to be so fascinating that I do not wonder that new men here are always ready to take hold of it. Even clergymen and actors are bitten with the desire to transform so many pounds of corn into so many pounds of spring chicken. The now successful manager, Mackaye, spent about a thousands dollars in constructing hatching machines and artificial mothers in Connecticut, but he found that the stage paid better, and his expensive devices may now be bought for the value of old tin. Enthusiasts will tell you that by the new discovery chickens may be made out of corn with absolute certainty. In Paris this has been done; but the conditions are entirely different here. There the land is valuable, and they cannot devote large fields to a few hundred chickens; the French climate is so uniform that the markets of Paris cannot be supplied from the South with produce which ripens or matures before that of the neighbourhood of Paris; the price of chickens is so high and labour so cheap that more care can be given with profit to one spring chicken than one of our poultry raisers could give to a dozen. Here we have plenty of land, the climate south of us is so far advanced in warmth, that even with steam we cannot raise poultry ahead of the South, and the margin of profit is so small that one failure with a large batch of chickens sweeps away the profits from several successful experiments. When persons wanted me to go into the project I declined and was called an 'old fogey.' One man spent a fortune on the enterprise in New Jersey, and at first was hailed as a public benefactor. What was the result of all his outlay and work. He managed to hatch quantities of our chickens every February; but although he could fatten them by placing them in boxes and forcing a fattening mixture down their throats, he could not make them grow; they had no exercise; they remained puny little things, and another defect soon appeared—though fat, they were tough and stringy. The breeder sent lots of them to me, and they looked fat and tender; but my customers complained that they could not be young, for they were tough and tasteless, and that I must have sold them aged dwarfs under the name of spring chickens. It was found absolutely necessary to let them run out of doors as soon as the weather allowed it, and by the time that they were ready for market, the souther nchickens were here and could be sold for less than these. The upshot of the business is that this breeder has sold out, and another man has now taken hold of a small part of his old establishment to try other methods of making it a success. As to raising turkeys in that manner, it will fall more disastrously than the chicken business. Size and weight are wanted in turkeys; and that reminds me, continued Mr. Knapp, that the newspapers ought to impress the country people with the necessity of improving their poultry stock; breeding in-and-in is ruining poultry; every year the stock we receive is deteriorating, and this is the cause. I could give you some striking examples from my experience of forty years in the business. Some years ago we poulterers thought that ducks were going to disappear from bills of fare altogether; they were tasteless, worthless birds, which people avoided. On Long Island a farmer made experiments in breeding with an old Muscovy drake, tough as an alligator and the common duck. The result was superb, and has changed the whole duck industry. If the farmers of Northern New Jersey, the sandy country best suited to turkeys, would bring from the west a few hundred wild turkeys, we should have an immediate improvement. I see no such turkey now as we had twenty years ago. The breast is narrow and the body runs to length; it is all neck and legs, and can be bought by the yard. Rhode Island sends us the best turkeys, but they are not what they used to be. If instead of attempting to beat Nature at her own game, the rich men who have money to spend would vote it to better breeding, there would be an improvement. I do not yet despair of seeing immense farms wholly devoted to raising better poultry than we yet have.—*Home and Colonial Mail.*

THE DEFECTS OF INDIAN AGRICULTURE, AND HOW TO REMEDY THEM.

ENGLISH people of late have been taking a great deal of interest in India and her people. To show this, some of the leading Anglo-Indian officials have been giving lectures and speeches in different places on Indian subjects. A few weeks ago, Dr. Hunter gave a

lecture in Edinburgh, which he took two evenings to complete, and he supplied much interesting information to the Scotch people which, they never had heard before. Some few weeks ago Sir Arthur Hobhouse gave two lectures on India; and Sir Richard Temple, the late Governor of Bombay, gave a lecture for the National Indian Association on Education in India, and a second lecture, at the Society of Arts, on Forest Conservancy in India.

Now what does the giving of all these lectures show? Surely and clearly, that the English people are perceiving the wants of India, and are anxious that some one should inform them more on the subject and enlighten them on India—the chief possession of her Majesty's dominions.

Little has been said in England on the Agricultural practice in India, so I will take this opportunity to try to give some information on this subject. The more so, because agriculture is the chief industry of India, and that on which the Indians live. There is no other industry worth speaking of at present. It is true, they have started many cotton mills, jute factories and others. But we must remember that these industries are but started, and not developed; but some mill-owners have already given up their new industry of cotton-spinning, because the repeal of the cotton-duty has given them a death blow, while it has seriously injured others. What other manufactures or city industries exist in India but those connected with the cultivation of the soil? Moreover, it is easily perceived that where agriculture is the sole industry, and where an average population of 212 persons to the square mile has to be maintained on it, the improvement of that industry ought to be prominent above all other considerations. Even in crowded England they have not got to feed more than 200 persons to the sq. mile and then look at the industries England possesses!

But to give some information on Indian agriculture, it is necessary that I should give a brief account of (1st) the agricultural population, (2nd) the agricultural products.

Every one in this country, who is interested in India, is aware of the fact, that caste prejudices in India are ruining the country. They throw obstacles in the way of everything; for instance, one who is a blacksmith by caste cannot follow any other profession, but that to which he was born. He cannot be a carpenter, neither can he be a weaver; but he must, if he wants to live by honourable means follow his hereditary profession. But the greatest drawback is, that he must follow it, whether he likes it or no, or is proficient in it or the contrary, for every profession requires proficiency and a knack to do the thing. I have heard of many families ruined from this, and have seen a few cases also. For when a man is unable to carry on his business, he must fall back on the money-lenders, who are the greatest curse of a country, and especially the way in which the Indian money-lenders do their business is very bad. They take the meanest advantage, and as they are generally a clever set of men, they easily entrap the poor man in their snares, and the borrower soon finds that he has borrowed a few annas to live that day, at an exorbitant interest, which will in all probability ruin his future prospects. In course of time, this very man will most likely turn out a beggar, and he can no longer face the money-lenders; and the family is ruined. I can give many an instance of this; many a family has been impoverished. And not only is it so with the blacksmith or the ryot (cultivator), but with every caste; they must all follow their respective hereditary profession. If any venture to deviate from this general rule, he is soon outcasted, and he has no society for the rest of his life.

This will plainly show that caste prejudices do a great deal of mischief, hindering people from prosecuting what they think they can best do. These prejudices stop travelling too on the part of many of the Indians to different countries, and thus prevent their gaining the knowledge and civilization which can only be derived from travelling in foreign lands and mixing with the society of people of different countries.

I have said that caste prejudices have done, and are still doing a great deal of mischief in various industries; but in all these is not it a providential escape for agriculture, that noble industry, that it brings no dishonor to him who pursues it! It is true that agriculture has its enemies in the caste system also, but those are but few and insignificant. The Brahmins among all their intrigues, and when they used their power so unworthily, have kept the art of agriculture free from this pollution, because they well knew the inevitable result of not doing so. It is open to all, whoever wishes to pursue it and no one is outcasted for following it. There are sundry things which a Ryot of a certain caste is prohibited from doing, for instance, a Hindu ryot cannot rear pigs or poultry, and a Mahomedan ryot cannot rear pigs. But these are, as I have said, few and insignificant restrictions. A man can easily farm without keeping either poultry or pigs. A farmer has only to keep them where there is a great competition. And this idea we never get until we come to see England. In the South of England, the farmers go in a good deal for pigs, which is a favourite thing with them, and they keep poultry in small numbers; but in the Lowlands of Scotland the practice is just the reverse, and a farmer there keeps a lot of poultry for home consumption as well as for market, and keeps one or two pigs solely for home consumption.

The people who form the agricultural community in India are poor in capital, generally uneducated, ignorant of the practice of other countries, and consequently without the knowledge of improvements which might well be adopted. But last and not least, they are without a leader who would devote his life to the well-being of the agriculturists, and to the improvement of agriculture in general. We all know very well that nothing can be done without experiments, and more especially among the Indian ryots, it is next to impossible to advise them to do a thing in a different way to what they have been accustomed to do. You must show the ryot by experiments that a certain thing can be done in a certain way which way is far superior in every respect to his own. Well, and this is what we want in India. But this is not the only or greatest want; the Land-law has many faults. I am not a lawyer, so I will not trespass in the province of the law; perhaps some of our lawyer friends will inform us on the Indian land-laws hereafter.

The holding of a ryot is very small indeed; it is generally about two or three acres, or it might be five acres. For a holding like the last the ryot must be rather rich. His land generally adjoins the village. His capital consists of Rs. 10 or £1, or might be as high as Rs. 20 (£2). The ryot lives in the village, and works day after day in his plot of ground, getting the help of his family during the harvest. But let us see what he does in his plot of land and what he grows there. We will suppose that it is a piece of arable land. The first thing he does is to plough the land with a wooden plough and a pair of bullocks. The plough has a triangular section; the body is made of wood, and just at the point which digs into the ground, there is an iron ploughshare, about 12 inches in length and about an inch and half in breadth. This is fixed to the plough lengthwise. There is no coulter, neither is there any skim-coulter. Now, supposing the ground is weedy, or has a thick swathe of natural grass, it is evident that the plough must proceed very slowly indeed and the pair of bullocks will have to exert an extra amount of strength to draw the plough. But after all, the want of coulter or skim-coulter is not of such importance as that which follows. The body of the plough has, as I have said, a triangular section, so of course the furrow made by it will have the same section. Now here is the problem: when the ploughman has thrown up the first furrow he turns round and follows one of the borders of the previous furrow, and next time he follows that border, and so he proceeds with his work. When the work is finished, what will a section of the field show? It will look like a saw, the hollow parts of which would represent the furrows, which are, of course, dug into the soil, and the teeth of the saw will show the parts on either side of the furrows, which are always left unploughed. Thus it is evident that only half of the field is really stirred, mind you, not ploughed, because in ploughing you bodily turn up the stratum of earth upside down, and then let the bottom layer, which is now exposed to the sun, be acted on by the weather. Now if we even want to stir the land, we effect this only in half of the field, though the operation is done over the whole field. The English drag-harrow will do it much better, it will stir the soil thoroughly over the whole field, at the same time collect weeds and break clods, and do the job more effectually than the Indian plough does. This will also do away with separate harrowing and collecting weeds. We will assume that the land is ploughed after the Indian fashion it is then left for a few days, when the sun dries up the clods. The ryot now comes with a wooden mallet and breaks the clods. The weeds are collected in a rather ingenious way. The implement used for this is very simple, and consists of a wooden or bamboo ladder, about 12 feet in length and 18 inches in breadth generally pulled by two oxen. This collects the weeds, as well as breaks the small clouds which might have escaped the eye of the husbandman. The weeds collected are burnt and the ash spread. In 98 cases out of 100 it is the sole manure applied to the land. When the land is ready the seeds are sown and left to Nature's care. The harvest time comes, and the crop is cut with a sickle, a light thing, smaller than the English sickle, which does the work slowly. There are various systems followed at harvest time, but as it is needless to pay more attention to this point, I will only notice it by saying that the ryots help one another in this important operation of their industry. The crop is carried to the stackyard, and there stacked round a tall tree with hardly any branches, which is generally planted for the purpose. I do not think the Ryot knows why he follows this practice, but this is the real reason. The tree acts as the centre-piece of his stack, and however compact the sheaves may be laid, there is always a certain portion of the space round the tree unoccupied by anything, and consequently this allows a current of air to pass through the stack, and prevents its over-heating and fermenting. When the weather is favourable, the sheaves are taken out from the stack and laid on a firm circular piece of ground, and trodden by four or five bullocks in a line, tied horn to horn. There is always a great loss in this operation, as however firm the ground may be, a considerable quantity of the corn sticks into the ground, which would not pay to dig out besides, when the animals get the chance, they do justice to their appetite. The winnowing process is a very old one indeed, and for this the ryot must wait for a favourable wind, but if there is a shower of rain or a gust of strong wind in the meantime he must bear the consequence. The corn is heaped up after thrashing. A framework, generally made of bamboo, and after the fashion of a sieve, about 2 feet by 18 inches is the next article resorted to. This is filled with a quantity of the corn, held up towards the wind, and then let the grains drop down gradually. The plump, heavy corn drops immediately near the operator, while the light husks, &c, are blown away from him. We will suppose that the winnowing is done thoroughly and under favourable circumstances, the corn stored up and taken to the market whenever convenient, and there sold. Here we will stop from following the produce of the farm as the moment it is sold in the market the farmer has no more interest in it. We cannot say anything with accuracy as to his profit; this is really a difficult thing in India. The value, of course, depends on the market price; and besides, India is a bad place for statistics and especially to deal with the ryot for the statistics of his farm why you might just as well ask a baby to give an account of the quantity of milk he had when he was three weeks old, and when he was seven weeks old, respectively.

We have followed the crop from the time it was sown to that when it was sold, and now it remains for me to notice some of the crops the ryot grows. In this he follows no regular course and he grows year after year the crop, which his land yields best. Has any Indian Ryot or his landlord asked himself what will be the result of the continuous growth of the same crop, year after year? Neither of them know it nor, do they care to know it, though it is the most important thing in farming. But I pity the descendants, who will inevitably sorely feel the ignorance of their forefathers.

Under the present exhausting system of corn-cropping the land is sadly and slowly being deprived of the elements of plantfood, and if this system be not at once checked and some new system introduced which will restore to the soil its exhausted fertility, the Indian soil will as a matter of course be unfruitful; and this is not only theory, but it is a fact, and there are many parts of India where they are feeling it already. Whence arises this poverty of the soil? Surely from its having been exhausted. This exhaustion of the soil is one of the chief sources of those Indian famines which are annually looked for in that country with dread and awe. The crops grown in India differ in different places, but for all that they are doing the same work in the soil: some are taking away from the soil something, and others taking away other things. This exhaustiveness of the Indian system of husbandry has been even shown experimentally. In Madras, places where they used to grow the fine tobacco some years ago are quite barren now, and will not produce the crop. And here I will mention one thing. Tobacco is one of the most exhausting crops, and carbonate of potash is one of its chief elements of food; consequently when tobacco is grown year after year in the same land, of course the land will lose this important element. Some of the Madras tobacco soils have been analysed and found to be in want of carbonate of potash, and consequently they do not grow any tobacco now. These experiments were made by the Madras Government, and they have discovered the mistake of the ryot. In the North-West Provinces wheat-land, which during Akbar's time yielded 1,140lbs. to the acre, now only gives 840lbs., and that very land would be made to produce 1,800lbs. in some of the eastern counties of England. But still, how few of the landlords are aware of the fact, still less are their tenants!

To notice some of the chief crops grown in India we will divide India for convenience, as follows:—(1) The Brahmaputra and Lower Gangetic basins, (2) the Upper Gangetic and Indus basins and Central India, and (3) Southern India, which will comprise the Eastern and Western Ghâts, Mysore and Hyderabad, &c.

In the first division, where the Ganges and Brahmaputra flow into the Bay of Bengal, rice is the principal crop. The ryot mainly depends on it to pay his rent and to provide his family with food; indeed, the rice grown in Barissal and the delta of the Ganges has a world-wide fame,

and much of it finds its way into the English market under the name of Patna rice, though Patna grows but little rice. But it matters very little to the Bengalee cultivator what the English people like to call his produce, as long as they consume it. The potato is another thing which forms the staple of the Bengalee ryot. Tobacco is largely grown in Northern Bengal while Cayenne pepper forms one of the chief industries of Eastern Bengal Maize, melons, and sundry other things are also grown. Patna is the chief place for opium.

In the second division wheat forms the chief crop for cultivation. Barley is also grown in some places. Maize is largely grown all over this division, and in rainy weather it supplies a great want of the ryot. A good deal of it is used roasted when green. Water melons and other melons are also grown here, and in the Punjab and higher up the country the apple, the grape, and other articles of luxury are grown. It is from these places that the Bengalee is supplied with his apples, cinnamon, grapes, and the various spices.

In the third and last division wheat again forms the staple food of the people. Here tobacco is grown somewhat extensively, and the tobacco from Trichinopoly and its district is made into the Trichinopoly cheroots, well-known among the Anglo-Indian smokers. Here in some places coffee plantations are to be seen, but this again is taken up by the English cultivators only. Various experiments have been tried by the Madras Government on the growth of exotic tobacco, but they have as yet not been successful. But the Madras Government has done one thing; it has established a Model Farm at Saidapet, and lately an Agricultural School was opened in connection with it.

Besides the crops noticed above, there are some others which are grown pretty nearly all over India, such as millet, the various varieties of peas, beans, onions, and sundry others.

We have now noticed briefly the present state of Indian agriculture. We have seen how the ryot holds his land, how he cultivates it, and last of all, what he grows in it; and I have also touched on the future of the present system of husbandry. Now I will make a few suggestion as to howwe might remedy the impending ruin of our country. These can only be carried out by the Indians themselves. They are as follows :—

1. The establishment of Agricultural Societies for the general improvement of agriculture and the agriculturists. These institutions must be in various districts, because of the variations in climate, soil, and produce. We at least ought to have four principal societies, and they must co-operate with one another. And these societies ought to start with (a) breeding of stock, for improving the native breeds, (b) trials and introduction of seeds and improved implements, (c) encouraging agricultural education for which prizes should be offered, (d) introduction of local rotation of crops, as this want is of utmost importance at present in Indian agriculture, (e) holding of annual shows for agricultural produce with gifts of implements and prizes. There ought to be local Agricultural Societies established, which can only be done by the Landlords themselves and not by the Government.

2. The Indian Government ought to help the Societies, by (a) providing them with seeds from other countries, (b) giving full consideration to any suggestion which the Societies may make as to land-tax, or any other thing concerning the ryot, (c) re-establishment of the Agricultural Department apart from the present combined Department of Agriculture, Revenue, and Commerce. The Indians should rejoice to hear that the Famine Commissioners strongly urge this. (d) Extensive irrigation-works and less irrigation rate on forage crops, which will enable the cultivator to keep a certain number of stock and consequently to procure manure for his land, (e) elements of agricultural education given in the village schools.

3. Landlords ought to take a more lively interest in their land and ought to spend some more money in its improvement than they have hitherto done. They ought to introduce new implements, seeds, and improved breeds of stock.

4. Forest conservancy more widely followed, by which the moisture in the land will be reserved, and we shall not suffer so frequently and dreadfully from those famines, which every year devastate districts after districts. This (forest conservancy) will also yield fuel from the underwood and prevent the dung from being employed for fuel. The importance of dung as manure cannot be too highly recognised. It contains everything that the plant requires.

There might be many more suggestions made in connection with the improvement of Indian agriculture, but I believe the four that I have mentioned are the most important ones.

Rajah Jaggut Singh of Bijnour has established an Agricultural Institute which he has endowed with a building and a large sum of money in Government Securities. He has done a noble work in not only setting example, of this kind in India, but investing his money for the welfare of the ryot. Who can say what wonders the Bijnour Agricultural Institute might do in time! Why do not the other native Princes follow the noble examples set by this Rajah?

The Madras Government has been trying several experiments for the last 10 or 12 years at its experimental farm at Saidapet, and is doing some very important work, little appreciated by the ryot, because of his inability to do so. Let us hope that the other Governments will follow the example of the Madras Government.

I will close this article with a few words of Mr. Hunter's, in his "England's work in India," where he says, "English writers who tell our Indian fellow-subjects to look to the Government for every improvement in their lot, are doing a great dis-service to the Indian races. The permanent remedies for the poverty of India rest with the people themselves." I quite agree with what Mr. Hunter says. If we want to remedy our poverty we must try to do so ourselves and not leave it to others. The Indian Government is willing to help us, but we must let it see in what way it can help us, and consequently we ourselves must first begin the improvement of our agriculture.

GOGENDRA NARAYAN, Jr. (of Kuch Behar).

—*National Indian Association Journal.*

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The Monthly General Meeting was held on Thursday, 17th March, 1881.

W. H. COGSWELL, ESQ., *President, in the Chair.*

The proceedings of the last monthly meeting were read and confirmed.

The following gentlemen were elected Members :—

Major, the Hon'ble E. Baring, H. H. Shewaja Rao Holkar, Messrs. C. E. Fendall, Edward Poppé, R. Williamson, Baboos Lalit Mohun Raya, Homchunder Gossain, and the General Manager Indian Glenrock Gold Mining Company.

The names of the following gentlemen were submitted as desirous of joining the Society :—

The Manager Rajmai Tea Estate, Assam,—proposed by the Secretary, seconded by Mr. J. E. Maclachlan.

Col. A. W. Twiss, RA, Commanding R. A. Morar,—proposed by Lt-Col. E. L. Hawkins, seconded by the Secretary.

O. G. R. McWilliam, Esq., C.S., Deputy Commissioner, Luckimpore, Assam,—proposed by Mr. F. St. C. Grimwood, C.S. seconded by the Secretary.

E. A. Roussac, Esq., Deputy Postmaster-General, Dinapore,—proposed by Mr. T. M. Francis, seconded by Mr. R. Blechynden.

CONTRIBUTIONS.

1. Wardle on the Wild Silks of India. From Government of India.
2. Proceedings of the Agricultural and Horticultural Society of Madras from May 1880 to February 1881. From the Society.
3. Report on the progress and condition of the Government Botanical Gardens at Saharunpore and Mussoorie, for the year ending 30th June, 1879.
4. Transactions of the Asiatic Society of Japan, Vol. 8, Part 4. From the Society.
5. Journal of the Asiatic Society of Bengal, Part 1, No. 4, and Part 2, No. 4 for 1880, and Proceedings for December 1880, and January 1881. From the Society.

PATRON OF THE SOCIETY.

Read the following letter from the Private Secretary to his Excellency the Viceroy, dated 24th February :—

"I have submitted to the Viceroy the Resolution passed at the monthly meeting held on the 17th of the Council of the Agricultural and Horticultural Society of India, soliciting his Excellency to allow himself to be named Patron of the Society; and he desires me to request you to inform the Council that it will give him great pleasure to comply with this request.

I am to add that his Excellency will have much pleasure also in subscribing Rs. 250 annually towards the funds of the Society, and I accordingly enclose that sum on account of the subscription for this year."

Resolved.—That the best acknowledgments of the Society be tendered to his Excellency for his kind compliance with the Council's request and for his handsome subscription to the funds of the Society.

GARDEN.

A report from the Superintendent of the Garden was submitted, of which the following are extracts :—

1. The garden labour has been kept well employed in clearing up the garden, removing aloes and other plants that had got too thick for ornamental and other purposes—transplanting, manuring, cleaning up the drains, and other general routine work.

2. Rose plants from Mr. Bull received on 7th December 1880. Of these the final loss has not exceeded 5 per cent. 136 have been planted out in an open spot, adjacent to, and south of west tank: another plot to north of same tank is being prepared for the remainder.

3. Rose plants received from Mr. Bull on 1st March current. These have not unfortunately reached in such good condition, as the lot received of 7th December 1880—fully half of them being dead or unlikely to recover.

4. Several new varieties of Crotons, Begonias, and Coleus have been added to the garden and propagated from.

5. 40 Rose plants have been received from the Khoshroo Beg, Allahabad, 20 of Rein des Violets, and 20 Princess Adelaide; these have been planted out to east of, and adjacent to, west tank.

6. *Peas.*—The following varieties were sown in the latter part of November :—Woodford Marrow Peas, Rising Sun, Maclean's little gem, Yorkshire Hero and Blue Prussian, in a biggah of land, the plot where it is purposed to carry out manure experiments for the Bengal Government; the seed is now being gathered, and a fuller report will be submitted hereafter. The germination was very good, and a fair outturn is anticipated.

7. *Annuals.*—The result of sowings have been successful, and they are now making a good show, in beds prepared on the large grass plot. Notably Antirhinums, Phlox, Petunia, Portulaca and Verbena; these will probably continue in flower for another month, and will yield a plentiful supply of seed in duecourse.

8. *Water.*—In consequence of the unusually dry season we have experienced, not even one shower of rain for upwards of four months, there has been a great demand on our labour force for artificial watering. The tanks are, however, tolerably well supplied with water, especially that to the west, and we may hope to tide over our annual difficulty in this respect.

9. *Propagation.*—The stock of fruit grafts, Roses and other ornamental plants that were propagated during the rainy season is tolerably large. We have succeeded in disposing of a good number of Roses, but still the supply is not equal to the demand. A large number of Rose cuttings were put down in January. A great many have struck root, and if they survive through the season, the garden will have a fair quantity for issue to Members.

10. The garden has a large quantity of Red Pumelow, Avacado Pears (Persea gratissima) and Citron plants ready for issue. Also Liberian and Arabian Coffee seedlings.

11. Caladiums are being potted off.

12. Seeds of trees and shrubs are being now gathered which will be useful to meet applications from Members.

13. *Manure.*—A large quantity has been received from Mr. H. A. Firth of Garden Reach and others at no cost to the garden. The garden carts being employed in conveying the same.

14. There has been full occupation for the two garden carts, delivering plants purchased by Members, carting manure, &c.

15. A specially fine lot of *Araucarias* of different varieties are now at the garden for sale, some being well grown and of fair size.

5th March 1881.

Supplementary Report.—At 6-45 P.M., on the 5th Instant (just after my first report had been sent in), there was rather a heavy fall of rain accompained by hailstones of considerable size. The damage to the glass houses, propagating, and leanto, was 284 panes of glass broken. The Mangoe and other fruit trees have been entirely stripped of this season's crop, which, before the storm, promised to be abundant. Some Araucarias have been slightly damaged, also several other plants of no special value. The rose cuttings mentioned in report of 5th instant have suffered likewise, and I very much fear ⅘ths at least will be lost.

Out of the lot of Rose plants received from Mr. Bull on the 1st instant, 50 arrived dead, 55 very poor and unlikely to recover, 97 promise well.

The acclimatized peas have been gathered, the quantity being 44 and-a-half seers. The outturn would have been better, but the hail and storm of the 5th destroyed fully three times the quantity collected.

The annuals have suffered very much, and the quantity of acclimatized seed that will be gathered will not be as large as anticipated.

The Garden has, on the other hand, benefitted by the rainfall; the draw off from the tanks of water for some eight days being almost entirely suspended, and the garden labor being deviated to other pressing work, one of the bamboo sheds for plants being entirely repaired and renovated during this period.

The Pineapple bed has got very thick, transplanting will be taken in hand as opportunity offers.

Special arrangements have been made for the different kinds of manure for farming experiments.

A large quantity of Poinciana regia seedlings ready for issue.

16th March 1881.

The Secretary called attention to the large collection of cutflowers on the table, consisting principally of Verbenas, Petunias, Phlox Asters, Pinks, Antirhinums, Browallias and Heartsease which have made a good show in the garden during the last two months, but have suffered considerably from the recent severe hailstorm. The Verbenas, Petunias and Snapdragons have been especially good.

REPORT ON FIBRE OF THE "BURRIÂRA."

(SIDA RHOMBOIDEA).

Read a letter from the Secretary to the Government of Bengal, forwarding some specimens of Burriara fibre received from the Rajah of Balihar, in the District of Rajshahye, for the favor of a report "on the quality of the fibre and its commercial value and suitability for the Indian and home markets."

Read also the following reports thereon by a section of the Fibre Committee:—

Mr. W. H. Cogswell.—I have been called upon on several occasions, and through various channels, to express opinions on samples of similar fibres submitted to me, and as these alluded to by the Government of Bengal in their letter No. 467/61 forwarding now under consideration, are identically the same, *viz.*, the "Sida rhomboidea," I think I cannot do better than preface my present remarks with the following report which I made to the Secretary of the Economic Museum in January of last year:—

"Replying to your No. 2901 of the 13th instant, I beg to say that I have carefully examined the sample of fibre prepared from the Sida rhomboidea, and which I return herewith. I am of opinion that none of the samples have been steeped a sufficient time; those subjected to 2, 3, and 4 days' submersion, particularly the former ones, are very imperfectly done, and the best sample subjected to 5 days' treatment, proves insufficient. There is much hard, harsh, barky, gummy substance adhering to the fibre which would have been removed under a more lengthy process. There is also much of what I term croppy ends about some of it which would not be apparent if the plant had been better matured before it had been cut. I would suggest that some of the longest stems of the plant should be taken, prepared in the usual way, and steeped for 7 to 10 days, about the same time as jute is steeped, care being taken that the steeping or retting process be not carried beyond the above period, as the fibre may become very weak, and towy in consequence. A large sample should be prepared, and I will get it tested in one of the Jute Mills, to see what percentage of warp yarn can be spun from it, and a correct value shall be arrived at. There is much in these samples of a soft, bright, glossy, clean fibre, but it is very short in comparison with Jute, barely half its length, the value being very materially reduced in consequence."

These samples now under review are from Rajshahye the same district as those alluded to in my foregoing report, I imagine, and probably from the same source; for whilst in those of the former, I pointed to deficiency of steeping, I have now to remark that some portions of these new samples have been kept too long in the retting process, the result being that some of the fibre has suffered in strength, and is somewhat towy, or to use a Scotch expression, most pregnant with meaning, it is "fosie," *i.e.*, the fibre is wanting in body, in substance, weight for weight, with that of a similar quantity of Jute. To a few, even experienced men, this fibre might be mistaken for that of fine Jute, though not one-fourth of its average length, when deprived of the root ends, as this has been. Its colour is glossy bright in the extreme, and of a very high order. The fibre is strong, fine, round, and of excellent spinning properties, and is well suited for the finest yarns of Jute manufacturers; some of it is so silky, as to render it in my opinion fit for higher purposes. I value it at about Rs. 4-8 @ 4-12 per bazaar maund. I think the flax manufacturers at home would be ready consumers of it. The fibre is somewhat more irregular, in staple than that of fine Jute, due in some measure if not entirely so, I think, to its treatment in the duration of steeping, drying, and bundling afterwards.

I believe this order of plant, the Malvaceæ, is to be found growing wild. Its cultivation, and treatment, and preparation of the fibre is exactly like that for Jute, and I think it is to be regretted that no data have been furnished as to the cost of its production, and the yield per beegah. It would be necessary to have this, to arrive at its correct commercial value in comparison with that of Jute, when a full opinion is required as to its spinning capabilities, &c., and a reliable commercial value has to be arrived at, it is necessary that very large samples should be submitted for experiment, if proper justice is to be done. Of its suitability for the Indian and Home markets, there can be no two opinions, and the following remarks fully endorse my own views. I am indebted to the courtesy and kindness of Mr. Alexander of Messrs Macneill and Co.'s "Ganges" Jute Mill to whom I gave the samples, to be passed through his reparing and spinning machinery, and the following is the result with the specimens I now submit:—

"I send per bearer the samples of 7½ lbs. yarn one warp, and the other weft, made from the sample of fibre you handed to me last week. There is also a sample of sliver from the drawing, and to allow of better comparison I send you a sample of our Hessian Sliver taken of the same drawing. The sample we had was so very small, only 3¼ seers, that it was with the greatest difficulty we got it made into yarn, which accounts for it being so unlevel. We could, however, judge that there would be no more difficulty in working it than the usual country Jute. There is more gum in the sample than is usually found in the common Jute. It is not quite so strong apparently, having been oversteeped in preparing, and the fibre rather coarser. There is no reason why it ought not to be largely used."

I forward the three samples in question.

Mr. W. Stalkartt.—Mr. Cogswell has given such a very full report on these samples of Sida fibre that I have nothing more to add. The question is, can it be produced as cheap, or nearly as cheap, as Jute.

Resolved.—That the specimens of the yarns above alluded to be forwarded to the Government of Bengal with copy of the reports.

In connection with the above the Secretary called attention to a report in 1851 on this Sida fibre which was submitted by the then Fibre Committee. The specimen was sent by Col. Hannay, from Assam, and most favorably reported on. Subsequently, a further and favorable report was given on specimens raised in the Society's Garden. These were forwarded to the Chamber of Commerce at Dundee, who intimated that the quantity was too small to admit of a definite opinion being given. (*See Journal of the Society, Vols.* 8 *and* 9 *old series.*) Since that time this fibre has been occasionally brought to the notice of the Society.

COTTON FROM THE CAWNPORE EXPERIMENTAL FARM.

Submitted a letter from the Assistant Director, Department of Agriculture, North-Western Provinces, forwarding certain specimens of cotton raised on the Experimental Farm at Cawnpore, and requesting an opinion thereon.

Submitted also the following report by a Section of the Cotton Committee (Messrs. Cogswell and Mosley) on these specimens:—

Mr. Cogswell.—No. 1. (Kulpahar)—Color good; staple short but strong, containing a little seed, and some leaf and stain, would class with "good" Bengal, worth	5¼*d.* per lb.
No. 2. (Bamia)—Color brown; staple long, strong and fine; free from seed, but containing a little leaf, and much stained and perished staple; would class with "good fair" brown Egyptian, worth	7⅝*d.* "
No. 3. (New Orleans)—Color fair; staple short but strong; containing a little seed, leaf and stain; would class with "middling" Orleans, worth ...	6½*d.* "
No. 4. (Tree)—Color good; staple irregular; free from seed and leaf, but containing a little stain; would with "good middling" white Egyptian, worth ...	6¼*d.* "
No. 5. (Upland Georgia)—Color good; staple fairly long but irregular; containing a little seed and leaf, and some stain; would class with "good middling" Uplands, worth	6 13/16*d.* "
No. 6. (Farm Bamia)—Color very good; staple poor, being short and weak; containing much seed and some leaf and stain; might pass as "middling" white Egyptian, worth	5⅞*d.*

Mr. Mosley.—Replying to your circular letter of 2nd instant I now return the six samples of *cotton* said to have been grown on the Experimental Farm at Cawnpore, and which I find to be very fully described in the Report by Messrs. W. Haworth & Co., the several specimens representing useful qualities for the European, and or China markets. Their indifferent condition is evidently the result of a want of proper care in the gathering of the bolls and subsequent separation of the fibre from the seeds, and it would have been interesting to know some particulars of the nature and extent of cultivation, as also whether the produce was raised from imported or acclimatised seed.

CROCODILE OIL.

Read the following letter from the Secretary of the Eglington Chemical Company, "Limited," Glasgow, in continuation of previous correspondence:—

We duly received your favor of 7th December last, and printed copy of Transactions of your Society, in which reference is made to Crocodile Oil. We are very much obliged for the extremely courteous manner in which our communication has been entertained and attended to, and we should feel ourselves still further indebted to you if you could procure and send us a small sample of the oil (any convenient size) and give us some idea of the price at which it could be obtained.

Our attention has been drawn to Crocodile Oil as being likely to be of use in *dressing* leather which is *tanned* by a new process in which we are interested, and we should like to make trial of it. We are sending you by this post some pamphlets and trade journals containing information as to this new tanning process which dispenses entirely with vegetable substances, and which we venture to hope may be of interest to your Society.

We shall of course, be ready to pay the whole cost of transmission of the sample of oil.

Agreed.—That the Secretary of the Company be requested to communicate direct with the parties mentioned in former letter, the Society having done their part.

Letters were read—

From J. McGibbon, Esq., late Director, Botanical Garden, Cape of Good Hope, offering to exchange plants and seeds with the society. (Agreed to.)

From the Superintendent of the Public Garden Allahabad, advising despatch of some Rose plants (Received).

From Mrs. Walker, Purneah, expressing her satisfaction with the flower seeds received last year Mrs. Walker adds—"I have grown potatoes yearly from the genuine Darjeeling seed with very great success both as to size and quality. May I send some specimens this season to the Society when the bulbs have been dug up. I think they will compare favourably with any kind grown in India. (Accepted with thanks.)

THE KHARAGORA SALT WORKS.

THE salt-tax is one of the largest sources of revenue to the Indian Government, (and the salt from which the tax is raised is manufactured chiefly, as might be supposed, along the sea coast near Bombay, by Tanna and Bassein, and in many other parts of India; but one of the largest and most important of the works is on the lesser salt Runn of Cutch, near the village of Kharagora, and it is of these that we propose to give a brief description. They were opened in 1872, all other works north of Bassein and on the Runn being closed at the same time, a branch line of the B. B. & C. I. Railway being laid to Kharagora from the great cotton station of Veerumgaum, distance of twenty-nine miles. In order to ensure the efficient collection of the salt tax, the works are all under the control of Government—that is to say, they are superintended by Government servants, and the salt is bought by Government from the native manufacturers at a fixed price, and is then resold with the amount of the tax added on, to wholesale and retail dealers, The cost of production is only a few annas per Indian maund of lbs. 82, but with the tax it is sold at about Rs. 2-13 per maund, and at this price tax does not come to more than three or four annas per head of the population. In order to prevent smuggling, the inducement to which is necessarily very great, it would be well if the Government could get all the salt manufacture of Guzerat into its own hands; but unfortunately several of the native chiefs have long exercised the right of manufacture, and though many of them have come to terms with the Government for a consideration, there are others who cannot be induced to yield their privileges, and these are a source of considerable inconvenience. A cordon of police has to be kept round each obdurate State, in order to prevent the entrance of untaxed salt into British territory, and this, it need hardly be said, cannot be done free of expense.

Ordinary sea-salt is obtained simply by allowing sea-water to evaporate in large shallow pans excavated near the sea-shore. After the water has evaporated the salt is scraped off the bottom of the pansin a powdered state, and is necessarily much mixed with earth and other matter in the wrong place, so that to make it like the driven snow it has to be put through process known best to the *babarjee*. But Kharagora salt is turned out in beautiful large crystals of the size of an almond or thereabouts, so hard that the wastage caused by removal is quite insignificant, and all that is required to make it fit for *sahib'* table is to crush it like ordinary sugar-candy. No wonder, then, that Kharagora salt is in high repute in Kattywar and the regions round about.

The Runn of Cutch is one of the most desolate and forsaken of places. It extends for miles and miles presenting nothing to the eye but brown, barren waste without a living or even a dead thing to vary the scene. In fact, it grows nothing but cracks, and these grow larger and larger as the hot weather advances. Perhaps the great deserts present a somewhat similar appearance, but with this difference that desert sand is loose and drifting while the Runn is all "hard-bake. It is supposed at one time to have been an arm of the sea, but the earth had indigestion, and there was an upheaval, and the unfortunate sea lost its arm. The whole Runn is permeated with salt enough to make it keep for ages, and if wells are dry in almost any part of it, there filters through the sand a brine of such saltness that sea-water is sweet beside it. It may be said almost any part of it, because there are three or four kinds of soil in the Runn, all lying in different layers, and it is only through one of them that brine percolates. This layer if found at a very great depth, and sometimes, however deep the men dig it, is not found at all. It must be very trying to the patience to have to dig so deep and get nothing for one's pains, but there is no possible means of ascertaining or even guessing which are the likely spots and which the unlikely. It must have been in some such spot that the Israelites found the wells which they called Marah. The site which the Government has chosen for its salt works is close to Kharagora, a small village lying on the outskirts of the Runn. One of the reasons for the choice was that Kharagora is in British territory, whereas other sites that might be suitable are in native territory. Another reason is that it has a moderately good water-supply—an important consideration in a land where aerated waters are not in vogue; thirdly, it is the most convenient point to which the B. B. and C. I. Railway could lay a line; and fourthly, the Agrias, or salt manufacturers, can be most easily obtained from the surrounding villages. As the salt manufacture only lasts from the beginning of October to the end of April, these Agrias transform themselves into cultivators during the rains, and it is expedient that they should not have to travel too far between the works and their fields, or, once off, they might never be seen again.

The works consist of between three and four hundred pans in ten rows, with a railway siding running between each two rows, and the whole is surrounded by a cordon of *chowkies*, so as to prevent the possibility of theft. Each pan is 250 feet in length and 60 in breadth nd has at one end a well: and very often, where for some unknown reason, the water in the well is not of the right strength, a shallow reservoir is built by the side of the pan, and in it the water from the well is allowed to stand for two or three days that it may purify and thicken before it is poured into the pan. The pan is a work of labour, if not of art. As the value of the salt depends much on its purity, there must be no soft mud left in the pan. The Agrias therefore work up the mud with their feet into a stiff paste, and then beat it down with heavy wooden mallets until it presents a smooth, hard, or rather tough surface, and this is a process which takes two or three months. The sides of the pans have also to be lined with grass, so as to prevent loose earth from falling in. The sides of the wells have likewise to be protected, only a firmer kind of matted basket work is used. The mode of raising water is primitive and ingenious. In a region which is swamped for four months in the year, it would be useless to get up any costly contrivance which would be destroyed by wet, and which could not be easily removed. The son of the soil, therefore, has hit upon a device which, while it laughs at the rain, can also be removed with the greatest ease. It consists of two long rafters resting near and on fulcrums fixed by the side of the well, and the short arm of each is heavily weighted with hardened clay, so as to bear it down and send the other end towering up over the well. Earthen chatties are suspended from the higher ends by ropes, and two men standing on planks above the well draw down the chatties until they have gone down into the depths and been filled; then letting go the ropes, the beams fly upwards, the chatties come up with a rapid swing to the top of the well, and are emptied into an earthen channel which communicates with the pans. It seems unaccountable that the earthen chatties, which are within a few inches of each other should not, like John Gilpin's bottles of wine, get "shattered at a blow," yet so it is. The great speed with which they ascend seems to protect them and the men at the top lay hold of them in an instant without allowing time for vibrations. It is not known whether the man who invented the process took out a patent. When the pans have been filled with water and allowed to stand, the formation of minute crystals soon begins to take place, and from then until the crystals are fully formed, or, technically speaking, until the "salt is ripe," the pans must be raked from end to end and fresh brine passed through them every day. If this is not done, all sorts of salt, such as Espom salt and Eno's fruit salt, gets mixed with the table salt, and the result is a mixture with which the Government does not know what to do. The raking is done by a man with a rough wooden rake, the spikes of which are made of common jungle twigs which are too pliable to injure the bottom of the pan. A foot or two of each twig remains on the upper side of the spar, and as the lower end gets worn down or broken off, all that is required is to knock through another inch or two from the top. During the earlier hours of the day, before the heat is great, each Agria trudges up and down his pan with this instrument behind him until no crystal has been left unshaken. So far the operations have been conducted according to primitive methods, but by the end of March the salt is ripe, and its removal takes place according to English ideas under the eye of some magnate of the Salt Department and it is therefore, of course, quite uninteresting. To state it briefly, the salt is piled up by the side of the pans; from these it is removed along the sidings in railway wagons to the great godown which has been built for its storage during the wet months; and from thence it is distributed as fast as it can be sold and the railway can carry it over the length and breadth the land until it has gone so far that it comes into competition other salt, which it cannot undersell owing to the cost of carriage.

A cultured and critical Englishman, sitting in the seat of the corner and viewing the scene, may say within himself:—"What a way of doing work is this? The pans should be of the best English make—if possible the agency of steam should be invoked—and then the outturn would be twenty times as large." It is highly improbable. Considering the extreme cheapness of labour, the indigenous plan is the best, and the introduction of exotic systems would probably only ruin several seasons' salt without, in the end, producing any improvement. Experience, after all, is the surest guide and cannot be successfully transferred from one country to another.

Towards the end of June, when the works have all been deserted and the sounds of labour have past ceased, and nothing remains to remind one of the past but have hardened pans and drying wells, suddenly one evening the south-west monsoon is ushered in with whirling sand-storms and howling gusts of winds, and heavy black clouds which come rolling up darkening the sky, and then burst in one universal torrent of rain over the whole land, filling the heart of man and beast with joy and gladness. During the hours of darkness the downpour continues and next morning—what a change? The Runn and salt works have disappeared, and in their place is one wide watery expanse, which soon teems with storks, sandpipers, and flamingoes and every form of aquatic life, and for the burning tropical heat of yesterday a soft damp balmy breeze blows over the face of Nature. Such is the variety which Nature furnishes to take away the monotony of our lives.—*Bombay Gazette.*

MINERALOGY.

AN official paper on the ores of Gwalior, points to a good opening for capital in that direction, the quality seems good, the quantity large, and wood for smelting purposes abundant, all that is wanted therefore is capital, and *that* will surely not we wanting long.

GOLD IN NORTH WYNAAD.—We have just received from a friend in North Wynaad, whose position and respectability preclude all doubt of its authenticity, the following information:—"Extensive auriferous reefs, more valuable than any yet found either in Devala or S.-E. Wynaad, have been discovered in Terriout, containing visible gold in large quantities, the pebbles (?) all over and through the ore being as large as raggee seed, and some even nearly as large as gram, justifying an estimate of over one lb. a ton; and another reef near to Mananntody, bearing gold, but in which silver predominates. This last favours the idea that silver also may become one of our great productions. Mr. Thomas' opinion, therefore, which you alluded to in one of your late editions, seems likely to be verified sooner than was expected."—*Athenæum.*

FUEL IN AMERICA.

THERE are 26,887 square miles of coal deposits in the State of Missouri, and a "calculating machine" has demonstrated that they can supply 100,000,000 tons a year for the next 1,800 years, and still leave a handsome margin for future generations. There is also an iron mountain in the State 228 feet high; its base covers 500 acres, and it is computed that the quantity of ore above the surface is 230,187,875 tons. Adjacent to the mountain is a "knoll" 581 feet high, with an acreage at the base of 360, and the iron ores in it are estimated at 13,972,773 tons. Large as this supply seems, it is said that in several provinces of China the supplies far exceed the quantity available in the whole of the coal fields of Europe. There are also large quantities of metals, and everything requisite to enable China to become a great centre of manufactures.

FORESTRY.

ACCORDING to an American contemporary, a giant of world-wide renown has lately been laid low, a victim to the levelling spirit that rules the present age. "Old Moses," one of the mightiest Sylvan patriarchs of California, was mercilessly cut down a few weeks ago, and the greater portion of his venerable remains have already been sold to the timber merchants of San Francisco. This colossal tree, judging by the number of rings contained in a sound section of its trunk, had attained the amazing age of four thousand eight hundred and forty-one years, when the fell fiat was issued for its destruction. The hollow portion of its huge and massive stem afforded standing room for nearly three hundred full-grown men. Its term of existence was a longer one than that of the world's known, or at least authenticated, history, and it must have been a "brave green tree" when Noah built his Ark. That so extraordinary a relic of the dim prehistoric past should have been thus ruthlessly made away with—unless its sacrifice were the outcome of some imperative necessity—cannot but be a source of universal regret, and we can readily imagine what the feelings of Professor Wendell Holmes, the true lover and chivalric champion of giant trees, must have been when the dread tidings reached his ear that "Old Moses" had fallen before the axe.

OUR FORESTS AND CLIMATE.

AT frequent intervals during the last quarter of a century our forests have been the subject of discussions in the columns of the Press and of legislation within the walls of Parliament. We do not remember that any objection has been raised to forest conservation on the ground of its being uncalled for; but, in spite of all the discussions, and the measures adopted by sucessive Ministries, forest conservation, it is needless to say, is as far off accomplishment as ever. Outside of the colony, Victoria is credited with having exhibited a great deal of energy in this direction, but we who live within it know that it has no claim to any such distinction. Not only has every stick of timber been cut down in certain districts that has reached a size fit for props underground, but even the saplings that would in time have furnished other props, or have reclothed the area with timber, have been wilfully and wastefully destroyed. Throughout the whole of the diggings areas evidences of a most prodigal use of our forests may be seen. The little area around many a hut is rendered goat-proof by the use of thousand of saplings from the thickness of the finger to that of the wrist. These if left where they sprung would, ere this, have furnished supplises of the timber that is now said to be so much needed for mining. Our sympathy with the classes that are now declaiming against the proposed elimination of portions of the Bullarook country, formerly afforested, would be enlisted more strongly had not the miners themselves been the principal transgressors—the chief agents in bringing about the scarcity of timber of which they now complan. But, in the interests of the common wealth, these features of the case must be overlooked and attention be turned to the consideration of the best method of preventing further mischief, and of remedying, as far as possible, the evil that has been wrought. Hitherto, whilst we have legislated against forest destruction, we have taken no steps to give effect to the law. We have seen boards possessing no powers, or those so overriden by political considerations as to render them merely nominal. Beyond collecting licence fees from sawmillers, splitters, cutters, and owners of Jinkers employed in the forest, nothing has really been accomplished. The wasteful cutting still went on, nor did Mr. Casey's plan of handing over the forests in sections to local boards prove a better method of management than that it had superseded. The clearances continued, and local bodies reaped the pecuniary benefit instead of the State. Victoria is indebted to its Agricultural Department for having augmented the area of forest reserves by great many thousand acres, and for having inaugurated a somewhat better system of management. It has, however, been unable to obtain such new legislation as would enable it to effectively control the reserves; one bill after another has been drafted and presented to Parliament, only to be disposed of in the general slaughter, at the close of the season. The department whose well-directed energies have thus been wasted gains an undeserved reputation for doing nothing, and the forests remain, as before, a means of perpetrating electoral bribery. All this has been presented from time to time in our columns, together with the natural deduction that no effective conservation of forests can ever take place until those portions of the State property be taken from under political control, and placed in the management of an independent board. It is such a course only that the forests can be conserved, and, at the same time be made to produce a grand revenue. These immediately financial matters are, however, of secondary importance, in comparison with the effect a proper system of forest management would have upon our climate. The denudation of our mountain ranges means nothing less than permanent sterility and the ultimate reduction of the whole of the adjacent country to the condition of a desert. Of the effect of trees in modifying climate, the results of ringbarking on the ranges in New South Wales afford striking examples. Whilst the heights were clothed with timber small rivulets trickled down to the lowlands; but at certain times they ran nearly dry. After the timber had been destroyed the streams, when rain fell, became swollen to a great size, rushing rapidly down and carrying away to the sea the water that formerly was absorbed by the roots of the trees, and held partly by the leaves and vegetable matter on the surface of the soil, whence it was gradually evaporated, and thus exercised a modifying influence on the aridity of the atmosphere. The death of the timber is soon followed by the loss of the surface vegetable matter. As no fres layers are supplied, the soil is eventually laid bare, and as the climate of the locality has also become drier, the growth of grasses on the adjacent lowlands is lessened in vigour. When graziers ruthlessly destroy the whole of the timber by ringing in order to produce grass instead of trees, they do not calculate the mischief they are doing to the climate, or the effect their proceedings will ultimately have upon the grazing capabilities of the very country on which they have operated. In the interests of grazing some clearances may be necessary; but it is obvious that if every temporary occupier (Crown tenant) exercises the rights of a proprietor, by clearing the timber off the land he has taken up as a grazing run, the interests of the State will suffer in a manner that statesmen do not as yet appear to have realised. It may not be possible to prevent freeholders from "doing as they choose with their own;" but each colony can, at all events, prevent its property from being despoiled of its most valuable crop by its tenants.—*Australasian.*

CULTIVATION OF CAOUTCHOUC TREES IN INDIA.

IN Mr. Markham's recently published "Peruvian Barks," there is an appendix on the above subject, and from this and other sources the following account has been drawn up by Mr. James Collins :—

In January 1868, a paper appeared in Dr. Seemann's "Journal of Botany, on "The Commercial Kinds of India-rubber or Caoutchouc," by Mr. Collins. This paper was, for the most part a *résumé* of what had been written on the subject, and also contained the results of personal observations on the preparation and commerce of that article, together with an endeavour to fix the botanical source of the various varieties.

At the instance of Mr P. Le Neve Foster, and the distinguished botanist and traveller, Dr. Seemann the author of this article followed up the subject, and the result of his further researches were given in a paper entitled "India-rubber: Its History, Commerce, and Supply," read before the Society in December 1869. The concluding remarks in this paper are as follows:—

There is one subject which I would more especially recommend to the attention, not only of those present, but also submit to the attention of her Majesty's Government, that is, the acclimatisation of the different species of *Hevea* (and also incidentally, I would mention the species of *Isonandra*, which yield gutta-percha) in such of our own eastern possessions, as will be found best suited."

Owing to the prominence thus given, the subject of the introduction into and cultivation of, caoutchouc trees in India was not allowed to drop, and through the representations of Mr. Markham, Mr. Collins was commissioned to prepare a report on the subject for the Secretary of State for India. This "Report on Caoutchouc" was published in 1872. The following passage from it may be quoted here:—

"The cultivation of economic plants, and the acclimatisation in localities where the various conditions, which are so many elements of success, are more controllable than in their native habitat, has a very important bearing on the commerce of a country, and becomes the more necessary for the sustentation and improvement of trade and manufactures, as the march of civilisation and colonisation or the recklessness of native collectors reduce the area and number of spontaneous forest products. It may be taken as an axiom beyond all controversion, that we cannot long rely on the spontaneous products of the forests but that recourse must be had, sooner or later to conservation, cultivation, and acclimatisation in order to keep up supplies of all necessary vegetable products."

The recommendations were that the (1) *Heveas*, yielding Para caoutchouc; (2) the *Castilloas* Central American caoutchouc; (3) the *Vaheas*, Madagascar caoutchouc; (4) the *Landolphias*, African caoutchouc; and (5) the *Urceola elastica*, Borneo caoutchouc, should be introduced into India, and that the cultivation of the indigenous *Ficus elastica* should be forthwith attended to. Of the various plants mentioned, the relative values of their products were taken into consideration, the *Heveas* and *Castilloas* being specially mentioned.

These views were adopted, and steps taken to carry them into effect. Meanwhile, Mr. Collins sent out full instructions to a correspondent on the Amazons, and was fortunate enough to obtain seeds of the *Hevea Braziliensis* and plants raised from these seeds at Kew, were taken by Dr. King to India, in 1873. Thus India obtained her first Para caoutchouc plants. A still larger supply was collected and brought home by Mr. Wickham in 1876.

Still, not only were seeds and plants to be obtained but, as was pointed out, there were many questions to be cleared up. Further information was wanted on the physical and climatic conditions under which the trees best flourished, and the best methods of preparing the caoutchouc, &c., and for this purpose observations on the spot were absolutely necessary. In the selection of a proper person, Mr. Markham was so fortunate as to secure the services of Mr. Robert Cross, whose previous travels in search of cinchona plants, and his knowledge of the country and languages, eminently fitted him for the task.

Mr. Cross left England for Panama Isthums, in May, 1875, and first searched for *Castilloa* plants, yielding the well-known Central American caoutchouc. The species which he first met with proved to be the *Castilloa Markhamiana*, so named by Mr. Collins in honour of Mr. Markham. This species grows to a height of 160 to 180 feet, with a diameter of about fies feet and a full grown tree yields about 100 lbs. of caoutchouc. The wood is soft and spongy and rapidly decays. Some caoutchouc prepared from these trees by Mr. Cross was reported to be superior in quality to that yielded by the historic *Castilloa elastica*. The range, too, of these trees was so wide that in certain districts part of the year is dry. Of the plants collected, 134, flourished at Kew, and of these a goodly supply was forwarded to India in 1876.

Mr. Cross again left England in 1876, this time to procure seeds and plants of the Ceara caoutchouc tree, and further supplies of the *Heveas*. In both efforts he was successful, resulting in the establishment of 1,000 plants of *Hevea Brasiliensis*, and a goodly number of Ceara plants, all in fine condition at Kew.

The tree yielding Ceara caoutchouc till this time was unknown, and to Mr. Cross is due the honour of clearing up its origin. In trying to get up young plants he could not move them, till digging round the roots he

found them furnished with tubers of the size and shape of kidney potatoes and from materials brought home, the plant is recognised as the *Manihot glasiovii*, a near relative of the tapioca plant. Quotations from Mr. Cross's report on this journey have already been published in this *Journal* (July 12th, 1878), and the report is full of practical information of the utmost cultural value.

Mr. Markham sent the bulk of those plants to Ceylon, from whence, as he says, they can be distributed to suitable spots in India as soon as the Government are less luckewarm on the subject, and fully recognise the importance of the scheme. In Ceylon, the *Heveas* grew remarkably well, and some trees have reached a height of nearly 30 feet, with a girth of 14 inches. The *Castilloas* also do equally as well. Later information from Ceylon shows that private planters are taking up the question, and Dr. Trimen, the newly appointed Director of the Peradeniya Gardens has published for their use a series of instructive notes on the cultivation, based on the reports of Messrs. Collins and Cross.

As to Madagascar caoutchouc plants very little information is to hand. Mr. Markham mentions (*Journal of the Society of Arts*, April, 1876) that seeds of *Vahea* have been sent to India.

With regard to African varieties, Dr. Kirk has displayed much interest, and has procured many plants of the Landolphias. Mr. T. Christy has procured several plants of *Landolphia* S. Mr. T. Christie has procured plants of *Landolphia florida* and *Urostigma Vogeli*, as well as plants of an apparently new kind from East Africa yielding an excellent quality of caoutchouc, and some fine and healthy examples of these are now in that gentlemen's nursery.

Thus of the various introduced kinds it is pointed out that the *Heveas* produced the choicest and best caoutchouc, and are well fitted for the moist zones of India. Castilloas will grow over the largest area, and new homes can be found for them in the Western Ghâts. Ceara kind thrives on drier ground and may find a fitting home in the hot dry plants of India.

In the efforts to introduce these exotics into India, the primary recommendation to cultivate and conserve the indigenous *Ficus elastica* yielding Assam caoutchouc, has not been lost sight of. The first attempts commenced in 1873, were comparative failures; but since that date the superintendence has been placed under Mr. Gustav Mann, and under his able manaagement the experiment begins now to assume some importance and, roughly speaking, there are now 1,000 acres in Assam under this cultivation, and the trees are making vigorous and excellent progress.

One other plant deserves notice—a Burmese one—as likely to prove of great utility as a source of caoutchouc. It is the *Chavannesia esculenta* This plant, of a climbing habit, was always looked upon as a pest by the Forest Department of British Burmah, and every means taken for its extirpation, as it injured the teak trees. Mr. Strettell, one of the officers, however, discovered that it contained caoutchouc, and seems to have proved conclusively that it will repay cultivation. If this turns out to be the case, it will only be another exemplification of the fact that "a weed is an unutilised plant"

Thus, although but yet in its infancy, the subject of the acclimatisation and conservation of caoutchouc-yielding trees has arrived at such a stage that its practicability is placed beyond all doubt, and the Society may well congratulate themselves that the warm support accorded to the idea when first brought before them, has proved an important factor in the present state of affairs. Nor must the action of Kew be forgotten. The valuable aid and support given to Mr. Collins by Sir Joseph Hooker, and the great care he has bestowed on seeds and plants sent to that establishment, have been of the utmost practical moment.

As Mr. Markham says:—This if intelligently and continuously followed up, will thus ensure in the future, as the demand increases, a regular and large supply of the best kind of caoutchouc from British India."

GARDEN.

THE DECIDUOUS MAGNOLIA.

In presence of the ruin caused by our recent winters, we were pleased to notice at Sion the other day that the two sturdy trees of the Chinese magnolia were quite uninjured, and bristled with bold flower buds, ready to open in March. What a noble tree this is, and how worthy of our best attention! No doubt our hard springs sometimes disfigure it; but then, the beauty of the bloom is so fine when the season is at all fair, and the bloom is also so constant, that no trouble is too much to secure the tree a good position. At Sion the tree struck us as being very happily placed, not shaded or approached by others, but with some friendly shelter near; and the alluvial soil of the Thames valley seems to suit it well. The large evergreen magnolia, which forms so noble a tree in the west and south of France as well as in its own native country, is unhappily not nearly so valuable as a standard near London, though it survives here and there. With us it can only be usefully grown as a wall tree, and as such it is often very fine; but for the open there is nothing like the large deciduous magnolia.—*Field.*

PLANTS BLOOMING WITHOUT EARTH.

M. ALFRED Dumesnil, a son-in-law of Jules Michelet, and the editor of the first edition of Edgar Quinet's works, claims to have made an interesting and useful discovery—how to preserve plants in a perfectly vigorous state without any earth. Since November 1880, the date at which his researches proved successful, he has, with the exception of a six weeks' stay in Paris, been continually taking plants from the ground and applying his process to them; has never found the least interruption in their vegetative functions; on the contrary, winter and spring plants have blossomed with a vigour which, as an experienced horticulturist he has never seen in his garden. With the shelter of a glass, hellebores, taken up at the end of November and the middle of December have remained from two and-a-half to three months in blossom. Other plants, primroses, daisies, violets, auriculas, &c., have not only been in bloom for three months, but have thrown out new buds. Bulbous roots, small shrubs, exotic plants, such as azaleas and cyclamens, take equally well to the process. M. Dumesnil exhibited some specimens of plants, blooming whithout earth, in the Square Solverine, in Rouen, last December; and at his home at Vascoeul, about fourteen miles from that city, any one may have ocular demonstration of the results he has obtained. In any light, the discovery is an interesting and an important one, as its applications are numberless, and the fresh scope it would give to the floral decoration of interiors delightful to contemplate.

FRUIT GROWING IN THE UNITED STATES.

CONSUL Cridland, in a recent report, states that East Florida has very great natural advantages for fruit growing, and especially for the orange and lemon fruits peculiar to warm climates. Large districts in the countries situated between the latitudes of 27° and 29° 40' north, and longitudes 80° 30' and 82° 40' west, seem to be particularly adapted to the orange and lemon tree, and little else is profitably grown on such land. Formerly, in Florida, as in most of the cotton States, the whole time and attention of the people was engrossed in the cultivation of the cotton plant and the sugar-cane. Fruit-growing was looked upon rather with contempt, and no value was attached to the wild orange groves in the States any more than to the same quantity of other timbered lands. In fact, very frequently the wild orange trees were cut down and destroyed to make room for cotton and sugar. Of late years, however, the people have found out the importance and profits of tropical fruit culture, and the old wild orange trees are highly prized, and are converted into sweet oranges by grafting. The difficulty in regard to orange culture is the impatience for immediate results. The orange, if cultivated from the seed, requires from seven to ten years of attention before it begins to bear, and the lack of patience and confidence deters people from starting an orange grove, and presisting in its care. Experience has proved that there is no fear of frost south of Pilaka. The quality of the Florida orange, and the excellent condition in which it reaches the northern markets, renders it a most profitable crop. There can be no fear of an over-production of the orange or lemon when it is considered what a vast country has to be supplied. In 1879, 4,000,000, dollars' worth of oranges and lemons were imported into the United States and the orange crop of Florida was valued at over 1,000,000 dollars. From information lately published in the United States, it is estimated that the orange crop in Florida next season will be 100,000,000 of oranges, for which the dealers will give the growers 1,500,000 dollars. The orange crop will double itself every three or four years; and considering the reports to the Governor show that there are over 20,000,000 of trees in the orange groves of Florida, in future years the crop will be enormous, and exceedingly profitable, and if the 20 per cent. *ad valorem* duty continues, it will stop the importation of oranges from Sicily, Spain, and the West Indies. Persons who engage in the cultivation of an orange grove in those parts of Florida where frost is almost unknown, proceed there and purchase from five to ten acres of land. Suitable land for orange culture costs from 15 to 20 dollars per acre. The land is then fenced in, which can be done for 6 dollars per acre. Clearing the trees and grubbing the roots, if done thoroughly, will cost 20 doollars per acre. This work takes some months to accomplish. Persons are found who undertake not only to clear, grub, and plough the land, but to purchase the orange trees and set them out. Most people purchase and replant trees three years old. From 60 to 80 trees are planted per acre; to plant and set out 300 trees would cost 200 dollars. In two months after being set out, which is generally done in January or June, the trees are fertilised with guano: the ground ploughed heavily once a year, and lightly six times a year A crop of Southern peas is raised between the trees, and, when ripe, ploughed in to enrich the soil. The trees receive two applications of guano a year. They grow little the first year; after that they become firmly established in the soil, and grow faster. There are no serious diseases of the orange, in good soil, in Florida. There are a great variety of orange trees but none so good as the Florida seedlings, or native trees. In starting an orange grove, the land should be cleared of everything and well broken up. The holes for the orange seedlings should be 30 feet apart, and 18 inches deep, and four feet in diameter. Consul Cridland states that for a total outlay of 1,030 dollars, a person can have an orange grove in Florida which will, after the fifth or sixth year, beg in to yield a good income.

A BIG MELON PATCH.

MISSOURI boasts of possessing one of the largest and most productive melon patches in the United States. It is situated on the borders of Scott and Mississippi counties, and equals if it does not exceed in size and adaptation of soil and climate the famous melon patches of Georgia Indiana, and the eastern shore of Maryland. The St. Louis *Republican* describes it as a tract of sandy prairie, four miles wide and ten miles long, with a thin warm soil, just adapted to the cultivation of the melon, and such melons as are raised nowhere else in that region. There is much richer and deeper soil all around there, but it is not adapted to melon culture. This land is capable of producing 1,000 melons to the acre. At a place called Diehlstadt, in Scott County, there were shipped the past season 439 car loads of 1,000 to the car, and Bertrand, in Mississippi County, shipped 180 car loads, mostly to Chicago. The melon county was visited by 25 commission merchants from Chicago, who paid as low as 40 dols and as high as 140 dols. per car load, being an average of 70 dols. per car, the market price varying with the advance of the season and the number of melons ripening at the same time. Most of these melons were shipped over the Cairo and Vincennes and Illinois Central Railroads in fruit cars, properly ventilated and arranged for the purpose. These melons found their way not only to St. Louis and Chicago, but to most of the lake cities, and even to New York and Philadelphia.

Melons are getting to be such a staple of production that the cultivators are asking for increased railroad facilities to move the product at the present season, and recently the Hon Henry J. Deal, the newly-elected member of the Legislature from Charleston; Mississippi County, applied to Superintendent Super, of the Iron Mountain Railroad, with a petition numerously signed, representing that they would plant 700 acres more next year in melons if the railroad will give them a side track and station at a point on the Iron Mountain Railroad three miles north of Charleston, to be called Melon Station. Mr. Super gave assurance that he would comply with the request of the petition. Col. Deal estimates that 700 acres ought to produce 700 car loads, at the rate of 1,000 melons to the acre, making 700,000 melons. One man can attend to 25 acres of melons. The variety of seed used is that of the Georgia melon, which is very luscious and grows to a great size, some weighing as high as 60 pounds. The hills are planted 14 feet each way apart, and from three to four seed are put in a hill. They commence shipping melons about the 20th of July, and continue to the end of August.

ON THE MANAGEMENT OF THE CHINESE PRIMROSE, SINGLE AND DOUBLE.

THE single-flowered sorts of the much favoured China primrose are raised annually from seed which should be sown from February till May as according as they are wanted early or late. They should be reared in a temperature of 60 degs. night to 75 degs. day. The sowing must be very carefully done, as regards the point of covering. The seed must not be buried deeply, but yet should be covered sufficiently. Perhaps the best plan that can be taken with them as regards this point is to make the soil in the pot or pan in which they are to be sown perfectly even and smooth on the surface. Let the seed then be sown evenly and regularly, and pressed down level with the soil by means of a circular piece of board. A thin strewing of moss may then be laid on the surface to prevent excessive evaporation, and the pot or pan may also be covered with a piece of glass the better to prevent evaporation. The soil should be loam and leaf mould or well-rotted manure; a good portion of sharp sand should be added, to render the mass porous and thoroughly permeable to water. Drain the pot or pan thoroughly. If possible give bottom heat; indeed, there is no better place in which to start the seedlings than an old-fashioned hotbed or dung frame. Keep them close to the light, so that they may not become drawn and leggy. Pot them off singly as soon as the plants are fit to handle; let the first pots be 'thumbs,' and the soil the same as that recommended for the seed pots. They must never be allowed to become stinted or pot-bound till they occupy the pots in which they are to flower. The size of these must be determined by the size to which the plants are to be grown. Excellent blooming plants may be grown in six-inch pots, but if wanted for the purpose of exhibition they must have larger pots. For the latter purpose the seed should certainly be sown in March early. When the plants have filled their blooming pots with roots they should be well supplied with liquid manure, and never be allowed to become dry, as they will not in that case throw up their flowers vigorously and well. The best strains only should be cultivated, and these can only be obtained by dealing with thoroughly trustworthy houses.

Double primulas originate in the first instance from seed, but they can only be propetuated by means of cuttings after they have been raised. There is, however, a class of semi-double flowered sorts which may be raised from seed, and they are only second rate in value for the purpose of cutting to the full double kinds, as they last much longer in that condition than the single-flowered sorts. These require the same treatment as the single-flowered sorts, and are not worth the extra trouble of rearing by means of cuttings, except anything really good and worth perpetuating should be discovered among them. But those indispensable kinds named the old double white, fimbriata, Mrs. Eyre Crabb, delicatissima, and the old double red, and many others can only be raised from cuttings. The cuttings require to be taken in spring when the plants are in full growth, the shoots being cut as low down as insure a portion of the hardened old growth at the base of each. These should be put in small sixty sized pots in sandy leaf mould and loam well drained, and plunged in bottom heat of 75 degs. to 80 degs. Much care and watchfulness requires to be exercised to prevent damping, to which they are particularly liable if kept very close and moist. If they are done in an ordinary hotbed or dung frame, and with care they can be done in such with excellent success, they must have a little air night and day left at the top of the lights to let the superabundant vapour pass off. The only difficulty to be anticipated in doing them in the ordinary dung frame, besides the tendency to damp alluded to, is that of maintaining an equable temperature. But the strictest attention must be paid to this point if failure is to be avoided. When the cuttings are rooted they must be gradually inured to more light and air, and the potting should be attended to as the plants require more pot room. The compost should be rich but mellow, that is it should have been laid up in store some time before being used.—*N. B., Agriculturist.*

SPIRŒA JAPONICA (HOTEIA).

THE popularity which this plant has attained in this country within the last ten or twelve years, is a proof at once of its merits as a decorative plant and of the quick appreciation of a good thing by the lovers of flowers, among not only gardeners but the now gardening public. The plant was grown in gardens for a period long preceding its general popularity, but proved unfit for use in many parts of the country on account of its liability to be cut off by late frosts in spring, which destroyed its beauty for the remainder of the season. Only in the most favourable seasons or in the best parts of the country does it appear at its best out of doors. But the discovery of its adaptability to forcing for winter decoration in pots, brought it into requisition to a degree that no plant previously used for that purpose had attained. The demand quickly exceeded the supply, and for a time the plant was scarce and dear; but this was soon rectified by the Dutch and Belgian nurserymen, who now send us millions annually, at a price which little exceeds the cost of the carriage even in these days of cheap and rapid transit of goods from all parts. Some idea of the enormous numbers that are grown annually in this county may be gathered from the fact that many of the large growers for the supply of Covent Garden Market turn over upwards of a hundred thousand each. It is, in fact, one of the most popular of winter flowers, and one of the secrets of its popularity is its cheapness. It is easily produced at small cost on the Continent, where the climate is favourable and land and labour are cheap. Another recommendation that has contributed largely to its universal adoption for winter flowering in conservatories, greenhouses, and rooms, and for the no less important purpose of supplying cut flowers on a large scale for trade or home consumption, lies in the extreme simplicity and ease with which it may be pushed into flower as much as six months before its natural period of flowering in the open air. Home-grown roots have neither the vigour nor the quality to force early. They make late growth, which, as has already been said is liable to be checked if not utterly destroyed by late frost, or by the hardly less destructive influence of east winds, which are a characteristic in spring of our general climate: and in consequence imperfectly matured crowns are a result which operates against doing well when any attempt to force them out of their natural season of rest is made. Such roots may do fairly well for late forcing, but will not stand being pushed with the view of bringing them into bloom in January or February. By those who grow largely for market supply, the roots are destroyed if they happen to remain on hand over the forcing season, they are not reckoned worth the labour of keeping, nor would they pay the rent of the ground they would occupy to keep them, even if they have not been forced; while forced plants are simply regarded as rubbish, and treated as such.

When the roots are received from the dealers in late autumn, no time should be lost in getting them potted up; or if the number received happens to be beyond the power of the available labour at the time to pot up the clumps should at least be covered with soil sand or ashes, or any other protecting material, out of doors, still it is convenient to attend to the potting. They should on no account be allowed to lie about exposed to drought, or it may be also frost, which would injure them even in a dormant state. The pots should be no larger than what will easily accommodate each clump, and the quality of the soil is a matter of small consequence, provided it is open and porous. Sustenance during the course of growth under forcing must be provided by means of abundant and stimulating waterings, rather than by a concentrated compost, for the small amount of soil that can be got into any of the few sizes of pots usually employed along with the bulky clumps would give them little to depend upon. The plant is also so greedy of water after it has formed its fibres in the soil and started to grow, that it will imbibe almost inexhaustible supplies of water, a peculiarity which presents to the cultivator the readiest means possible of feeding and stimulating to any degree hardly possible by means of even the richest soil mixtures. In fact, as soon as the pots have become fairly filled with roots, they should be put in saucers, which should never be allowed to become dry, and the contents of which should be largely mixed with cow's urine or manure water made from cow or sheep dung. The plants should be placed as near the light as possible while growing, so as to ensure short stubby growth. They should also be so placed as to have abundance of light and air on all sides, otherwise they are liable to become lop-sided and disfigured. The neat, nicely porportioned habit, the elegant foilage and flower spikes, and the fact that it stands in need of no such thing as stakes render it one of the most desirable subjects for decorative purposes that could be desired at any season of the year, and guarantees that its popularity will not be soon abated, for it has no rival in its way, and is never likely to have one in which all its merits will be combined and excelled at the same time.

Spiræa plumata, this is another Japan plant of rare decorative excellence, but being later in flowering than the preceding, it is not possible to force it so early into flower. Yet it is so choice in its tint of deep crimson rose colour, and its inflorescence is so dense yet graceful in style, that it is welcome at any season of the year, indoors or out of doors. The plant is hardier in constitution and less liable to be injured by late frosts in spring than the preceding, but it also in districts that are liable to visitations of late frosts, becomes disfigured by them, though not quite destroyed for the season. A sunny position and moist cool bottom suit it best out of doors, and in pots it requires similar treatment to the preceding but with somewhat less moisture.—*North British Agricultural.*

JAPANESE GARDENING.

JUDGING from a paper read at a recent meeting of the St. Petersburg Society of Gardening, the Japanese must be allowed to have distanced us altogether in at least one branch of education. Enthusiasts in gardening would fain live to see the day when every householder will have his plot of garden, and will know how to cultivate it. The universal spread of such knowledge seems to be almost as hopeless as the possession of plots for its exercise in our large towns. But the Japanese, M. Grigorieff tells us, are all taught gardening in their schools, and all have their little plot of ground. They are instructed in practical horticulture, and in the artistic arrangement of bouquets, and all classes, from the palace to the cottage, manifest a passionate love of such humanising and healthful occupations. Nowhere in Europe, we are assured, are gardens so numerous, or the love of floriculture so extensively developed. One very curious art they seem to have brought to great perfection. Their gardens often being small, and their taste leading them to take pride in the possession of trees of the bigger species, they have gradually developed the art of dwarfing them without in any way sacrificing their general shape and proportion. Father and son and grandson will grow an oak, for instance for fifty years or more, and will take means of preventing it ever attaining more than eighteen inches, or a couple of feet in height, though still presenting all the characteristics of the full-grown tree in trunk, branch, and foliage. Among their family treasures to be handed down from one generation to another, may often be found a well-arranged garden, established in some antique specimen of Japanese pottery in the shape of a capacious bowl. Within this receptacle will be walks and trees and flower-beds, with a great variety of floral favourites all dwarfed to the proper proportions. One further development of this odd manipulation of natural objects, is the patient training of the minified trees and shrubs into the forms of birds and beasts, or any other object that may strike the fancy, or may be suggested by the accidental shape of the plant, a refinement of gardening which in barbarism very nearly approaches our fashion of clipping shrubs into plum-puddings, or perpetually snipping trees that might become beautiful, into close imitation of German toys.—*Globe.*

NEW WAR OF GROWING CYCLAMENS FROM SEED.

IT may be said that in my case the use of cocoanut fibre and charcoal is a mania, but I must write to inform your readers of the complete success of an experiment with that mixture which I have been trying in the raising of cyclamens from seed. On October 19th I sowed a packet of seed just below the surface in a saucer filled with fibre and charcoal, and from that time never allowed it to become dry. It stood on a shelf in a badly-lighted dwelling-room. On November 23 I burrowed down to see how the as yet invisible seeds were getting on, and I found that though they had not sprouted, they had made fine strong roots, which had firmly taken hold of the compost. On November 30 they had all come up, and are now in their second leaf, and I shall plant them out in the ordinary way as soon as possible.—GIROFLE, in the *Garden.*

LILIUM GIGANTIUM.

THE following from the *Garden* may afford a useful hint to some of those who cannot succeed with this magnificent lily:—"This is undoubtedly one of the finest of all the lilies, both as regards flowers and foliage. It is empahati ally a lily for the south or milder parts of our climate. In Devon and Cornwall, in some old country gardens it is a sight not readily to be forgotten; there it not unfrequently grows from 6ft. to 10ft. in height, and bears from six to 12 flowers. In Devon, quite near to Exetor, I have seen great clumps of this lily, bulbs and offsets 3ft. or more in diameter, and when the first great glossy leaves unfurl themselves in the spring, the plants are very ornamental even if they never blossomed, as indeed with me they sometimes do not. In pots it does fairly well, and has a great liking for strong manure-water once or twice during the week, and, of course, plenty of moisture at all times. Even when supposed to be at rest in winter the soil should ever be maintained in a moist condition. Both in pots and in the outside borders this plant is now making active growth, albeit as yet below ground, and I am persuaded that at no other season do lilies suffer so much from drought at the roots as at this season, when a good sound foundation for the top growth of leaves and blossoms is being made."

TEA.

SO it is proposed to give us a quasi-governmental tea warehouse. We have heard quite enough of governmental interference to inspire us with a lively dread of encountering any more of it. When the tea industry wants a warehouse, it will provide it. If the object be to help the industry, we can point out a variety of modes, by which this can be effected. Let the Government interest itself in providing better means of communication between the tea districts and Calcutta. The intercommunications be are not what they ought to be, let them be seen to. Let the obnoxious forest rules be modified. These, and fifty other things might be done with advantage to all concerned, but we do not want any fresh interference.

WE have repeatedly urged of late, the propriety of making only the finer classes of tea. That low class teas can be made to profit is beyond a doubt, but it is suicidal to flood the market with a large percentage of cheap low-class teas at the present moment when the industry is suffering from a plethora of stock. The *Produce Markets Review* in a recent issue, says:—"There has been less activity in the Indian tea market, and most descriptions are, not so firm. The low broken proportion is considerably in excess of the demand, and as much of it is below the average quality, even of this class of tea, prices have further declined. If the supplies of low broken sorts continue as large as during the past few weeks, values may reach an exceptionally low point, as the lower China sorts are being freely offered at declining values. The medium kinds of which the grocers appear to hold good stocks at present, have also declined, although not to the same extent. The competition for the finest teas shows no abatement, and the few fine brands brought forward have fetched extreme prices." THIS exactly bears out what we have been urging.

SINCE the advent of tea rolling and withering machinery, a radical change has taken place in the mode of manufacturing teas. We do not now speak of the present rage for underfermenting to produce pungent rasping liquor, but of the system which is now in vogue by which panning is considered unnecessary. There can be no doubt that the abolition of panning received an impetus, from the demand for this rasping tea, because panning tones down this very bitter quality in the leaf, and while rasping tea is required, it is of course not advisable to have this flavour toned down. The demand above referred to was brought about by the custom of using Indian tea for the purpose of strengthening weak China qualities, and such being the case, rasp may have been an advantage. Now, however, that Indian tea is assuming its proper place in the market, and is being largely consumed alone, and unmixed with the China article, the raspy flavor is objected to, and hence we find Messrs. George White & Co. in a recent review of the trade, retrospective and prospective saying:—

Under the old fashion, that is to say, the system of hand rolling, &c., there used to be some very fine tea made, and we are inclined to think that one of the processes, *viz.*, that of panning, which has been discontinued, might be revived to advantage.

We quite agree with this remark, an effort to make only the finer grades of tea would tend materially to raise Indian tea in the estimation of the consumer, and would at the same time prove of considerable benefit in reducing stocks.

AT the present moment, and for a few months back, tea stocks in London have shewn a tendency to become less, this tendency has been frustrated to a certain extent by the enormous quantities of tea which have been pouring into the market, and these being principally of low quality, have tended to keep down prices. The cause of lowering stocks is, of course an increased demand, this too may be largely brought about by the low prices prevailing, but there are not wanting sure signs that it arises principally from an increased consumption, and a steadily growing taste for the Indian article as compared with that of China. This is a healthy sign, and the tea planters of India will surely make an effort to meet this revival half way, by making a tea which will give satisfaction if drunk alone.

A LONDON Trade journal has the following on the tea sales for week ending 18th March:—

"Of the 12,000 packages brought forward at the public sales a very large portion consisted of low broken descriptions, which in consequence of their undesirable quality, fetched exceptionally low prices. Souchongs and Pekoe Souchongs sold at comparatively steady rates, but for the medium sorts previous quotations were scarcely maintained. The finer qualities were actively competed for, and readily taken at full prices.

THE PROPERTIES AND USES OF TEA.

IN a book written by Professors Bentley and Trimen, entitled, "Medicinal Plants," we read:—"The principal use of tea is to form an agreeable slightly stimulant, soothing, and refreshing beverage. It was formerly believed that tea, from the *theine* it contained had the effect of diminishing the waste of the body, and as any substance that does this necessarily saves food, it was regarded as indirectly nutritive; but Dr. Edward Smith has shewn that on the contrary tea increases the bodily waste by acting as a respiratory excitant and in other ways. From containing gluten, tea has also been regarded as directly nutritive. As a nervine stimulant, tea may be taken with great advantage in headache and neuralgia, and in other affections caused by the exhaustion of the system from depression of nerve power. Its effects in such cases are said to be analogous to quinia, and hence tea has also been given in intermittent fevers—in asthma, whooping cough, and other spasmodic disorders. Tea is drunk by upwards of 500 million people," in other words by half the human race.—*H. & C. Mail.*

SHIPMENTS OF TEA FROM CALCUTTA.

FOR the information of our home readers, and as a complete record of the movements in Indian tea, we give the following particulars of tea shipped from Calcutta during 1880, with the names of the firms shipping, taken from the annual "export summary" of Calcutta:—

	1880.
Messrs. Williamson, Magor and Co.	6,665,841
" Begg, Dunlop and Co.	3,751,293
" Macneill and Co.	3,442,046
" Schoene, Kilburn and Co.	2,818,196
" Balmer, Lawrie and Co.	2,060,742
" Barlow and Co.	2,036,901
" Stanley and Co.	1,446,887
" Lyall, Rennie and Co.	1,238,112
H. P. Thomas, Esq.	1,205,785
Messrs. Octavius Steel and Co.	1,045,685
" Andrew Hoyes and Co.	985,043
Messrs. Macknight, Anderson and Co.	958,786

BOHEMIAN TEA.

We translate the following from the *Indische Mercuur* for February:—For some years a shrub has been cultivated as *Thea Chinensis* in different parts of Bohemia, the leaves of which prepared as green and black tea, has been used to a considerable extent even in other countries. Not only is it brought into the market as "Chinese" tea, but it is used to adulterate the finest sorts of tea. A botanist named A. Vogel has identified the plant as *Lithospermum officinale*, and has subjected it to a careful botanic-chemical analysis, regarding which we give the following particulars:—Theine or any other alkaloid is not found in the plant, but only cellulose, gluten, gum, glucosides, fat, etheral oil, rosin, tannin, chlorophyl, albumen, acid salts, water, &c. Dextrine also appears to be present in it. The composition differs greatly and notably from that of Chinese tea.

COFFEE.

LIBERIAN SEED.—A correspondent writes: "I notice the fruit vendors at Polgahwella Station are offering Liberian cherries at one cent. each. Where do they get it? One would scarcely suppose the proprietors of Liberia Estate (in the neighbourhood would put such a premium upon coffee stealing by thus opening the path to thieves.

LEAF-DISEASE IN NATIVE COFFEE.—It would appear that the injury caused to Native Coffee gardens in the Central Province by repeated attacks of leaf-disease, has been far greater than that suffered by estate coffee, probably, from the fact that the native gardens are less cared for, and are generally in a less vigorous state of health than plantation trees. But be this as it may, the accounts we have received from the Central Province, and especially from the neighbourhood of Badulla which we all suppose to be the peculiar home of coffee, are most distressing. On a recent occasion, when the Government Agent, on a tour through his province, brought to the notice of the headmen of Uva, the heavy arrears of revenue, the reply was that the villagers were quite unable to meet their payments in consequence of the serious losses they had by their native coffee gardens having almost entirely gone out of bearing. In proof of this, the Agent, we believe, was shewn a number of Native Coffee gardens which certainly bore out all the statements made to him. We mention this particularly, because in the Uva country, coffee is always supposed to thrive far better and yield better crops than in any other part of the Island, yet, here we see native gardens suffering most severely from the attacks of this pest.

MADRAS COFFEE AT MELBOURNE EXHIBITION.—Madras has a second time beaten Ceylon, by standing first in the order of merit as to the quality of her coffee. The former defeat was at the Sydney Exhibition, and the Colombo Press on that occasion attributed Ceylon's want of success to the fact that their planters had not got sufficient warning, and that the demand for specimens was made at an inconvenient period of the year. On the present occasion not only had they due warning, but a special Commissioner was sent to the Exhibition to uphold the merits of their exhibits, while Madras was unrepresented as regards a local Commissioner. We shall be curious therefore to learn the cause to which this second triumph of Madras is attributed by the Ceylon Press.—*Mail.*

THE correspondent who writes about the great prevalence of grub on his and his neighbours' estates, should take heart by what has been accomplished in other directions. No pains must be spared to clear out this serious pest, and that it can be done we have no doubt. Having enjoyed immunity for several years, these insects have multiplied exceedingly, and no wonder. But the indiscriminate slaughter hat has been going on in Maskeliya and Lindula for months past, must have the best effect in lessening the number of our enemies. The efforts of planters must not slacken until they have completely overcome this insidious foe.

LARGE SALE OF CEYLON COFFEE PROPERTY.—We believe the Elkadua group of estates have been purchased by a company of gentlemen for somewhat about Rs. 210,000. There are about 1,200 acres of coffee and 50 of tea. Among the coffee there is much cinchona, over 500,000 plants having been counted, from six months to four years' old. The coming crop of coffee is said to be between 10,000 and 12,000 bushels parchment. Should such be the case, there is no doubt the purchase is a good one for the Company; and we congratulate them on having, as their representative here, one of the shrewdest, most far-seeing and popular men in the planting community. We wish him and his partners every success.

THE BRAZIL COFFEE CROP.—Messrs. Robert von Glehn & Sons in their monthly coffee report, make the probable deficiency in the coming, as compared with the last, Brazil crop equal to 1,200,000 cwts. and hew altogether a total deficiency of coffee crops in 1881-82 of 2,270,000 cwts. as compared with 1880-81.

LEAF-DISEASE IN COFFEE.

A CORRESPONDENT, writing on leaf-disease in Coffee, says:—"Something might be found out of the manner the Arabs treat the coffee plant. Mocha is the king of coffees—either by climates or treatment—perhaps it is that arid climates grow the best. There remains no doubt of the plant being perfection. Doctors and botanists may advise a good deal to counteract influences, yet Arabia is the starting point, because it gives the best. Dent's Concession in Borneo in its most arid parts should give next to Mocha. English coffee growers must beware that the Spaniards in Manilla do not take to, and surpass them in coffee growing. Any one finding out the mode to dispense with fungus, I think must do so from Arabia. If any one cannot be found here who has been in Mocha, by bringing one plant with fungus upon it, and taking it to Mocha in a week, perhaps he might find out the Arabs' secret from that add to his fortune in a treatise on the plant, and thus surpass those who cannot dispense with fungus. Of all the people who have gone to plant coffee, has one of them asked at Aden anything about ?"—*L. & C. Express.*

THE JAVA COFFEE CROP.

IN the British Consul's Report for 1879, dating from Batavia, we read:—The coffee leaf-disease (*Hemileia vastatrix*) broke out in March on some plantations in the neighbourhood of Buitenzorg, but its effect does not appear to be so pernicious to the growth of the shrub as it has proved in Ceylon.

No doubt the comparatively fair crop of that year deceived the Consul, but we suspect very different will be his opinion of leaf-disease now that 1880's crop shews a falling-off by more than one-half the previous return. We have received the following authentic statement from a reliable quarter:—

Java Coffee Crop:—1879 and 1880.

District.	1879. Private coffee.	1880. Private coffee.
	cwt.	cwt.
Bantam	2,550	971
Buitenzorg	15,786	7,286
Preanger	6,436	2,185
Krawang	15,543	2,793
Cheribon	1,032	1,214
Pecalongan	5,461	1,948
Samarang	42,014	38,857
Kadoe	3,096	1,518
Bagelen	2,368	425
Solo	114 750	88,086
Djocja	644	182
Pasoeroean	37,946	20,643
Probolingo	206	486
Betakie	729	729
Kedirce	6,079	5,464
Madioen	101.382	9,714
Total private coffee cwt.	265,625	182,446
Government	1,529,951	678,537
Total for Java	1,795,576	860,983

It seems that a good deal of coffee was lost in 1880 for want of transport, labour, &c., but of course, it is rank heresy to preach such a doctrine to the Dutch authorities in Java, for they believe their management of their colony to be perfection.—*Ceylon Observer.*

THE COFFEE TRADE.

IN its commercial retrospect for 1880, the *Anglo-Brazilian Times* refers with some natural pride to the position of Brazil as the largest producer of coffee in the world, and quotes the following estimate of the total production in 1855 and in 1878:—

	1855. Kilo-Tons.	1878. Kilo-Tons.
Brazil ...	163,400	225,500
Dutch poss ...	71,322	91,404
West Indies	29,300	41,800
Ceylon ...	28,780	53,422
South Africa	22,315	35,890
Arabia ...	6,176	2,799
Central America	4,000	4,000
Philippines ...	3 500	32 500
Oceania ...	1,358	3,396
Africa ...	—	150
	330,154	490,843

Brazil has of late been blest with abundant coffee-crops in the year 1878-79, the exports alone reached 3,705,830 sacks of 60 kilos, and those of 1879-80 were 2,909,05 sacks, while subsequent returns are of a promising character. Ceylon, on the other hand, has suffered in many recent years from adverse crops, in a great measure owing to the disease of the plant, and 1878 was a year specially adverse in this respect. Brazilian coffee, however, does not to a great extent reach this market, which is mainly the European rendezvous for colonial growths, and the figures below which are taken from the Board of Trade Returns, show our trade in this article during the past four years:—

Imports.	1877. cwts.	1878. cwts.	1879. cwts.	1880. cwts.
From Ceylon ..	780,341	539,151	627,433	540,676
From other British possession	274,032	269,917	307,381	355,246
From Brazil	187,912	200,998	260,297	272,442
From Central America ..	228.686	153,544	260,141	208,388
From other Countries ..	138,096	136,797	162,182	179,187
Total Imports ..	1,609,717	1,273,410	1,617,389	1,555,939
Consumption—				
Home consumption ..	293,127	298,154	309,788	290,802
Exports	1,104,397	1,017,062	1,288,624	1,174,514
Total Consumption ..	1,397,524	1,315,216	1,598,412	1,465,316
Stock in bond, Dec. 31 ..	871,918	808,104	805,708	389,933
Prices per cwt.—				
Ceylon Midd. Plantn. ..	107s.	95s.	104s.	86s.

With increased stocks and diminished consumption, it is scarcely to be wondered at that prices have fallen heavily, and do not as yet show any signs of revival. Indeed, prices are exceptionally low just now.

CACAO.

It has been ordered by the Admiralty that for the future cacao will be offered to sailors in lieu of grog. Formerly sailors under eighteen were not allowed grog. Under the new rules there is to be an extension of age to twenty, and foremast men within that category will receive instead of a ration of rum, an allowance of 'soluble chocolate' during the middle of morning watch in addition to tea and sugar. The issue of spirits to officers will also be discontinued, but those gentlemen will receive instead a monetary compensation amounting to the 'savings price' of the spirits. This arrangement, it is to be presumed, will not preclude the officers of the ward-room mess from enjoying or offering their friends a *petit verre* with their coffee after dinner, but it will, we suppose, render the midshipmen utterly grogless. No doubt pessimists will see in this an additional reason for supposing that the service is going to the dogs, but the sweet 'little cherub which sits up aloft' will not turn his back on poor jack because he has become the victim of enforced temperance. On the contrary, it will, it may be hoped, keep him in view with a still more kindly eye.

CINCHONA.

The Trade in Cinchona.—The action of the Madras Government in continuing to compete with private planters in the growth and export of cinchona bark was becoming a matter of serious moment to cinchona planters in Ceylon as well as in India, and Mr. Dickson Manager of the Scottish Trust and Loan Co. of Ceylon, deserves the thanks of the planting community generally for his protest, addressed to us, though the necessity for further action has fortunately ceased on account of a resolution come to by the Madras Government that in future the bark from their estates shall not be sold but used for the manufacture of alkaloids for use in India. It seems that they do not intend to follow the example of the Bengal Government and have the alkaloids extracted on the spot, but will have this done in England. We suspect, however, that this will not be for long, the expense of freight proving a formidable item of the expense.—*Ceylon Observer.*

Some new specimens of cinchona have been introduced into Madras by Mr. Cross on behalf of the Government, having been obtained by him in South America at a distance of about three hundred miles from the coast. Amongst the plants are three *calisayas* of the Santa Fe variety, which yield on analysis 10 per cent. of pure sulphate of quinine.

In his excellent work just published, describing the introduction of cinchona cultivation into this country, Mr. Clements Markham gives reasons for spelling the word "chinchona" and not "cinchona," or "cinhona," as it was spelt by Linnæus, and the altered spelling has raised a botanical dispute. The title "chinchona" is given to the bark tree as a memorial of the cure of fever by its means in 1638 of the Countess Chinchon, wife of the Governor of Peru.

Cinchona Bark.—The Government have shipped by the P. and O. steamer *Ancona*, 488 bales of cinchona bark from the Government cinchona plantations on the Neilgherries. The bark, which is valued at one lakh and twenty thousand rupees, is forwarded to the Secretary of State for India.—*Madras Paper.*

We have repeatedly pointed out that the time has come when the Government should cease to cultivate cinchona. This industry has long passed the experimental stage, and it should now be left in the hands of private enterprise.

CINCHONA.

As a great deal of cinchona is now being raised by private enterprise, the attention of Government has recently been directed as to what would be the best means of dealing with their own plantations, so that they may not compete with private enterprise. It has been decided to send the bark to England, not to be sold in the market, but for the manufacture of alkaloids for use in India. The work has been undertaken by a London chemist, who has had the good fortune of coming across, in the process of extraction of alkaloids, two other alkaloids which are cheaper, and just as efficient febrifuges as the quinine now used.

CEYLON CINCHONA.

We congratulate the Messrs. Mackenzie Proprietors of Craigellachie, one of the highest estates in Haputale, on the splendid prices, secured for their crown bark, running from 4*s.* 6*d.* for young branch to 8*s.* 1*d.* for good and fine stem per lb. as reported from Mincing-lane. This is by far the highest rate paid for Ceylon bark at the sale reported by this mail, but renewed crown from "Hoveton Gardens" (on the Nilgiris we suppose) realized 8*s.* 10*d.* to 8*s.* 11*d.* per lb. It would be interesting to know the age of the Craig trees from which the 8*s.* 1*d.* bark was taken.

CINCHONA SHAVING.

A Lindula correspondent sends us the following note on the new process of 'shaving' cinchonas instead of barking them as by the old process. 'I have been watching the process of shaving off the outer bark containing the sulphate of quinine by means of the small easily handled spoke-shave, the invention of Mr. Wm. Smith of Mattacoolie estate, and was much pleased with what I saw. The ease, rapidity, and certainty with which the removal of the outer bark is accomplished, render these implements most useful in the hands of coolies who could not be trusted with the old barking process with the knife. A four-year old tree was completely shaved in the space of certainly not more than two minutes, and the celerity with which the thin strips of bark can be dried, as compared with the drying of thick bark is most marked. Mr. Smith is having a very simple but powerful form of press made for baling up the thin shavings, and this will enable him to turn out a large quantity of the dried shavings daily. What I saw in his store, appeared to be perfectly dried, by merely having been spread out on the floor under the iron roofing. This work will afford employment for women and children.—*Ceylon Times.*

SERICULTURE.

One of the vernacular journals has been informed by a native silk merchant that owing to the prevalence of intense cold in Europe, the silkworm rearing industry is expected to suffer considerably. In consequence of this silk is being actively purchased both in the districts and the capital, and stocks are becoming so scarce that the foreign firms in Yokohama, who are as a rule quiet at this season are very active.

TOBACCO.

"Tobacco is an Indian weed,
Green at morn, cut down at eve,
The smoke that does from it ascend
Shows man's life must have an end;
Think of this when you smoke tobacco."

During the last fifteen or twenty years, while roaming around, we have not failed to notice that, although in every society—whether that to be found round the civilized board of a festive friend, or at messes, in clubs, at Mansion House dinners, or at the dinners of civic and other public bodies—there are always to be found plenty of men who do smoke, still there is a respectful minority who do indulge, if it be an indulgence, in the use of tobacco in any way, either by smoking, snuffing or chewing it. We have observed, at select parties, that perhaps one-half are smokers, the other half are non-smokers. Of course, we only here allude to *males*, and not to that delightful portion of the human race that played such sad havoc with Lord Byron's hero, Don Juan,

"For woman's face was never form'd in vain
For Juan, so that even when he pray'd
He turn'd from grisly saints, and martyrs hairy
To the sweet portraits of the Virgin Mary."

We have, of course, in our, peregrinations, wanderings, and "tramps abroad," sometimes found even lovely woman indulging in tobacco, in a mild way however, in the form of cigarettes, and also at the same time aping her lords and masters, in the way of gently "pegging;" but then there are, popularly speaking exceptions to every rule, although some philosophers strenuously deny this; such maintain that a rule can have *no exception*. Not long ago, when dining at a party in a private residence where there were eighteen intelligent males assembled around a friend's hospitable board, we had exactly nine smokers, and nine non-smokers whereupon a little argument arose about the smoking of tobacco, whether it was healthy, or an unhealthy practice; whether it, soothed as well as stimulated a man, or, indeed, whether it had any particular kind of effect at all, one way or the other. We all know, that is those who have learned to smoke, how awful are the first sensations resulting from the primary use of the narcotic plant. *Punch* indeed, most beautifully and poetically pourtrayed the effects of a first indulgence, where two young and lovely maidens were shewn in a handsomely furnished room, one lying down on the sofa, dishevelled, pale, and unscreened altogether, and the other, coming up to her, says, "Lotty, dear, what is the matter with you?" The dishevelled one replies, "Oh, dear, I have just had a whiff of Charley's pipe, and I feel *so ill.*" We can call to mind, after more than half a century, the awful effects produced by our first whiff out of the gardener's "cutty pipe;" we were rendered *harmless* for several hours, and having betaken our small sell into the strictest privacy, we had been voted by mama, and our sisters and aunts, to have been for the time very good and quiet.

Tobacco is certainly a most wonderful plant, and its use is universal over the entire world, civilized, semi-civilised, semi-savage, or savage; in fact, from "Nova Zembla to Peru." Akin to the intoxicating liquors we consume are the narcotic substances we indulge in; and if the history of the former in their relations to the social state be full of a melancholy interest, that of tobacco is still more striking and extraordinary. We may safely indeed say that to the economical statist, not less than to the physiologist and psychologist, the connection of man with tobacco, in different countries, forms one of the most wonderful chapters in his entire history. In supplying his natural wants and cravings, man passes through three successive stages First, the necessities of his material nature have to be provided for, and "beef and beer," or what may generally be termed food and drink, represent the means by which these necessities are supplied. Secondly, he seeks to assuage—as the British soldier so often does—the cares of his mind, and to banish uneasy reflections. This is effected by fermented liquors: and savage and civilized tribes, near and remote—the houseless barbarian wanderer, the settled peasant, and the skilled citizen—have all found out, by some common and instinctive process, the art of preparing fermented drinks, and of procuring for themselves the enjoyments and miseries of intoxication. And so, whatever material is employed, and heaven knows their name is legion, for the purpose,—whether the toddy of the palm tree, the sap of the aloe, the juice of the mango or of sugar-cane, the syrup of honey, the must of grape, the expressed liquor of the apple and pear, the wort of malted grain, the barley brew of Robbie Burns or the milk of the Tartar mare,—in every instance the substance called *alcohol* is produced by the fermentation, and forms the intoxicating ingredient of every liquor. Thirdly, man desires to multiply his enjoy-

ments, intellectual and animal, and for the time to exalt them. This he attains by the aid of narcotics, chief among which are tobacco and opium. And of the many other kinds of narcotics it is interesting to note that almost every country or tribe has its own special narcotic either imported, or aboriginal; so that man's instinct has led, somehow or other, to the universal supply of this want or craving also. The aborigines of Central America smoked and chewed tobacco, dreaming their dull lives away in smoky reveries, ages before Columbus was born, or the colonists under Raleigh brought within the precincts of the Court of the Mighty Queen Bess. Indeed, of all narcotics, tobacco is in use over the largest area, and among "all the people, the nations and the languages" of the world.

Tobacco is believed to be a native of tropical America, and it was cultivated and used by the natives long before Europeans knew anything about it. Columbus in 1492 found the chiefs of Cuba smoking cigars, and Cortes met with it subsequently when he penetrated to Mexico. From America it was brought to Spain, at what time it is not exactly settled, Nicot brought it to France in 1560, Sir Francis Drake and Sir Walter Raleigh brought it into England in 1586. Mr. Lane tells us that it was brought into Turkey and Arabia early in the seventeenth century, and it is known to have found its way to Java about 1601. Since then the cultivation and use of the plant has spread over a very large portion of the habitable globe. In Europe it has been raised with success in every country, and forms an important agricultural product in Hungary, Germany, Flanders, and France. In Asia it is cultivated in Turkey, Persia, India, Thibet, China, Japan, the Bahamas, the Philippine Islands Java, Ceylon; also in Australia and New Zealand. It is too, the most extensively cultivated, the most hardy and the most tolerant of changes in temperature, alititudo, and general climate. The finest qualities are raised between the fifteenth degree of North latitude, that of the Philippines, and the thirty-fifth degree, that of Lattakia in Syria Salt and tea are the only two articles consumed by man which can compete with his consumption of tobacco. Though in Shakespear nearly everything, under the sun is alluded to, there is no mention made either of smoking, chewing or snuffing the weed. Although the sweet bard of Avon talks much of the delights of wine, ale, and fermented drinks. King James, of happy memory, said of the use of tobacco, "A custom loathsome to the eye, hateful to the nose, harmful to the brain, dangerous to the lungs, and in the black stinking fume thereof nearest resembling the horrible Stygian smoke of the pit that is bottomless." However, the people of England, when it came among them, were not to be deterred from using it by King James's "counterblaste to tobacco," nor by the papal bulls which Pope Urban VIII. thundered against its use. In Russia the knout was mercilessly laid on the hides of those who indulged in the use of tobacco, for a first offence; and death was the punishment for a second offence. So again in the East the priests and Sultans of Turkey and the Shahs of Persia declared smoking a sin against their holy religion; yet, notwithstanding all this opposition and persecution, the people smoked, and now the Turks and Persians have become the most inveterate smokers on earth. The Burmese, too, of all ranks, and classes, of both sexes and of all ages, down even to infants of tender years, smoke cigars, made of chipped tobacco, rolled up in a green leaf a foot long sometimes, and the smoker will pass his cheroot round the company, just as we hand round side dishes at dinner. In China, too, when in 1641 it became a practice to smoke, the Emperor Tsung Ching issued a prohibitory edict, with about the same results as the 'counter blaste" of James, or the bulls of Pope Urban. And now-a-days the practice has become so universal throughout the Celestial Empire, that very female over eight years of age wears, as an appendage to her dress, a small silken pocket to hold tobacco and a pipe, just as the native females of many sects in India carry about their little betassled and ornamented bag, with betel and cloves or cardamoms, which they listlessly chew squatting on their hunkers in that way, so common and peculiar to the women of the lower orders of India.

To show how much the cultivation of tobacco has increased, we find that in 1662 the quantity raised in Virginia, at that time the chief producer of tobacco, was only 60,000 pounds, and the quantity exported from the Colony in 1689 only reached 127,000 pounds. During the 192 years which have since elapsed, the produce of Virginia has risen to twice as many *millions* of pounds! Turning to Great Britian, we find that in 1689 the total importation was only 120,000 pounds of Virginian tobacco, part of which was re-exported, and now the consumption in the United Kingdom alone is over 50,000,000 pounds! In 1821 the consumption of tobacco per head of population was 11¼ ounces, in 1871 it rose to 1 pound 5¼ ounces per head! In 1881 the number of retail dealers in tobacco in the United Kingdom was 83,493, now there are about 250,000. The gross produce of the duty in the raw tobacco retained for home consumption, and the duty on the cigars, snuff, and cavendish, and other kinds of manufactured tobacco, consumed in the country all together amounted to £7,907,794 in the year 1876, or about the total sum of money expended on our navy! Some twenty years ago an enterprising gentleman estimated the average consumption of tobacco by the whole human race of 1,000,000,000, at 70 ounces a head, and the total produce and consumption of this favourite narcotic at 2,000,000 tons or 4,480,000,000 pounds at 800 pounds an acre, this would require upwards of 5,500,000 acres of rich land to be kept constantly under tobacco cultivation. Since this calculation was made the population of the world has increased to 1,439,000,000, and the use of tobacco has extended, and its consumption per head notably increased. Nevertheless, it is doubtful whether as large sums are now anywhere spent upon tobacco as were spent in England in the time of King James I., who says "some of the gentry bestow three, and some four hundred pounds a year upon this precious stink."

There are three ways of using tobacco,—smoking, snuffing, and chewing In whichever of these ways it is used, the effects produced appear to be much the same in kind, they differ chiefly in degree; but although so extensively used, it is notable that few persons can distinctly describe the effects produced upon them by tobacco; why they began its use, and for what reason they continue to use it. Any smoker, chewer or snuffer can verify this for himself or herself. In future census takings it would be instructive to have some columns entered for tobacco consumers, such as "smokes," "chews" "snuff," some may practice all three. It would be useless to enter into the vexed question whether tobacco is hurtful or the reverse when used in any of the ways indicated here: opinions differ widely on this question. Dr. Pereira, Dr. Christism, Dr. Prout, and a host of other learned physicians have given their opinions freely on the effects of the use and abuse of tobacco. We may, however sum up in a few words. Smoked to excess, and especially by persons not generally accustomed to use it, nausea, vomiting, purging, universal shakiness, staggering, convulsive movements, paralysis, torpor, and death result. Some cases have been recorded of persons who killed themselves by smoking eighteen pipes at a sitting. We have seen some men who never had a cheroot, pipe, or cigar out of their mouths, except when sleeping or eating, or perhaps when in the society of ladies. With some persons it never agrees, and these should, of course, eschew the seductive weed in any form; but both Doctors Pereira and Christism, say that "no well-ascertained ill-effects have been shown to result from the habitual practice of smoking." Dr. Prout, however, held a different opinion, and he sums up by saying: "It happens with tobacco as with deleterious articles of diet, the strong and healthy suffer comparatively little, while the weak, more predisposed to disease, fall victims to its poisonous operation. Surely if the dictates of reason were allowed to prevail, an article so injurious to the health, and so offensive in all its modes of enjoyment, would speedliy be banished." Just so, Dr. Prout; but where do you find people using "the dictates of reason" even in the ordinary and daily use of the necessities of life, "meat and drink?" Few, indeed, ever learn, even from sad experience, "*what to eat, drink, and avoid.*" With regard to the use of tobacco, we can only say in the words of Pope—

"Who shall decide, when doctors disagree,
And soundest *casuists doubt* like you and me?"

We publish the following papers at this Office:—

THE INDIAN AGRICULTURIST.

Rates of Subscription, including postage.

STRICTLY IN ADVANCE.

For India	Yearly	Rs. 12 0
	Half-yearly	„ 7 0
For Europe	Yearly	„ 13 8
	Half-yearly	„ 7 8

Single copies, Re. 1, back copies, Rs. 2.

Advertisements for the "Indian Agriculturist" should be sent in not later than the 23rd, to appear on the 1st of the following month.

THE

WEEKLY CEYLON OBSERVER.

THE best newspaper publication in the world for tropical planting intelligence and all matters affecting the statistics of production and the practical cultivation of coffee, cinchona, tea, cocoanuts, cinnamon, cacao, and other similar products. The proprietors and editors (Messrs. Ferguson) have had prolonged experience in Ceylon, as journalists, and in connection with planting. The paper is largely circulated in Ceylon, India, British Colonies, and the United Kingdom, also in Java and Brazil.

Subscription, including postage 18 rupees (£1 16s.) per annum in advance, and Advertisements at 9d. per line of 10 words.

Also published (annually) by Messrs. Ferguson, at their "Observer" Office, the "Ceylon Directory and Hand-book of Information," on subjects affecting tropical cultivation as well as all Ceylon matters—1,000 to 1,200 pages demy octavo, price, 8 rupees (16s.) per copy, including postage; Advertisements, Rs. 20 (£2) per page, or Rs. 12½ (£1 5s.) half page. Orders (with Bank Drafts) for all the above received at the "Observer" Office, Colombo, Ceylon; or through Messrs. Geo. Street & Co., 30, Cornhill, London, and Messrs. J. Haddon & Co., 3, Bouverie-street, Fleet-street, London.

THE INDIAN AGRICULTURIST.

A MONTHLY

JOURNAL OF INDIAN AGRICULTURE, MINERALOGY AND STATISTICS.

VOL. VI.] CALCUTTA :—WEDNESDAY, 1st JUNE 1881. [No. 6.

NOTICE.

The INDIAN AGRICULTURIST *will be supplied to all Schools and Missionaries in India at half price.*

CONTENTS :

NOTICE TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

ACKNOWLEDGMENTS.

CORRESPONDENCE.

THOSE RIVAL PLOUGHS AGAIN.

(To the Editor of the Express.)

DEAR SIR,—I have just read your issue of the 23rd March last, on my return from the interior. It contains a letter from Mr. Gavin Jones, in which he brings a serious charge against me.

Mr. Jones writes :—With regard to Mr. Martin's plough, permit me to inform you that the model is mine, and, in the specification I filed in January 1879, I described that the stilt may be of any suitable form, and I was greatly surprised to find Mr. Martin claiming the plough as an original production, when, I am informed, he obtained the pattern from the Government Model Farm here, and during my absence in England brought it out as his own invention.

As you have probably not seen Mr. Jones' plough, I send it to you for inspection together with one of my own, and the ordinary country plough as it is used in these parts. If you will look at the three implements carefully, you will observe that my plough has been borrowed from the Indian and English ploughs, and, as I have explained in my memorial to the Governor-General in Council (*vide* printed copy annexed), it is nothing more than a combination of the two principals, having the shape of an Indian with the working capacity of an English plough; the frame pole and stilt being made of wood, the mould board of sheet iron, with a removable share of steel of the English pattern. In fact it bears the closest resemblance to the native plough, in all its parts and shape, the standard or frame being simply made with a sharper angle to admit of it penetrating to a greater depth than is possible with the wider angle in the native standard.

No one who has studied the history of ploughs will, looking at Mr. Jones' production, fail to recall to mind the primitive implement for ploughing used in ancient times, *viz.*, a block of wood with a share and pole stuck to it ; a fact of which Mr. Jones appears to have since become conscious and brought out another plough constructed on a different principle. Nor will any one looking at my plough, differ from the opinion expressed by the *Indian Daily News* that, "whilst it is in reality the ordinary country plough, no one can look at it without seeing it has borrowed largely from the English plough," or contest the description given of it in the *Indian Herald* that "it is a compromise between the ordinary country and the English ploughs."

I cannot understand what Mr. Jones means by asserting that the *model* is his. A wooden standard, pole, and stilt is not his, but the old Indian idea, as you will find on looking at any native plough in the country ; and if he merely claims to have adjusted the English mould-board and share upon these, a comparison of his production with the native implement will shew any one that he has not been v

successful either in giving a proper shape to the standard, or placing the stilt in a proper position, two important considerations in the construction of a plough. But because Mr. Jones has failed in this respect, is it necessary that no body else should attempt to carry out the idea to perfection? Mr. Jones, however, is not the man who has taken the first step in this direction; there have been others before him, as I have lately seen various adaptations from native ploughs attempted in several parts of the country on this principle.

Mr. Jones may have been abroad at the time I was getting out my patent, but his friends were not slow to publish a report in the papers that I had borrowed from his plough; and that he had done the same from the one made by the Department of Agriculture; nevertheless I am thankful to say that such contrivances did not succeed in preventing the Government from granting me a patent.

Mr. Jones seems to be oblivious of the fact that in the Home Department of the Government of India, styled the patent office, are preserved sketches and specifications of all inventions, and patents are not granted without a careful comparison in order to prevent any infringement of public rights: nor does he seem to have any knowledge of the law which governs and protects patent rights. If he felt sure I have infringed on his patent and deprived him of the fruit of his labour, as he makes out, he should have applied for redress to a court of justice, instead of carrying his grievance before the general public who have not seen the ploughs, and are not in a position to test the truth of his assertions.

The superiority of my plough has been so conclusively demonstrated all over Bengal, and lately in the N.-W. P. at Boolundshuhur, that, riled at his defeat and unable to beat me in fair contest, he now comes forward to claim the credit of my invention.

This, however, is no place for a controversy on such a subject, and apologizing for the length of this letter, I conclude with a hope that you will not fail to give it a corner in your paper and your valuable opinion on the points at issue.—Yours faithfully,

W. MARTIN.

Phuppond Concern, 25th April 1881.

THE RIVAL PLOUGHS.

(To the Editor of the Express.)

SIR,—I have been away from Cawnpore, therefore have only just come across Mr. Martin's letter which appeared in your issue of the 30th ultimo. Before replying, I must premise by stating that I have neither the time nor the inclination to enter into a newspaper controversy, particularly on a technical question which needs diagrams to illustrate.

As Mr. Martin has sent you one of his ploughs, and you are already in possession of one of my "Ryot" and "Kathkar," you will doubtless be able to respond to his appeal and satisfy him and the public whether his is, or is not, a copy of my "Ryot."

Mr. Martin's description of his plough, to say the least is very ingeniously contrasted with that of the ryot, but I think you will find on inspection of the two that it will apply equally as well to both, naturally, for they are identical—both have "the shape of the Indian with the working capacity of the English plough. The frame, pole, and stilt being of wood, and the mould board of sheet iron with a moveable share of steel of the English pattern."

Mr. Martin appears to me rather vague in the use of the word "principle." Would he be so kind as to favor the public with an accurate definition of the term particularly in its application to the description of the ploughs under notice, I am not aware of having "brought out another plough constructed on a different principle;" doubtless he alludes to the "Kasthkar"; if he will be good enough to examine it—being I presume a competent mechanic and gifted with inventive powers—he will observe that the "principle" of the "Ryot" and "Kasthkar" are identical, and that they differ only in construction. I suppose it is upon this vague "principle" of reasoning that it suits Mr. Martin, to look upon the two ploughs from his own stand-point, and he would, no doubt, like the public to view them in the same light, but let those who are interested in the matter examine and test the two practically, they will find that I have not so signally "failed" in the adaptation whilst he has succeeded to "perfection." It is very gratifying however to find Mr. Martin so kind as to give me credit for the fact that I became "conscious" of the shortcomings of the "Ryot" and brought out the "Kasthkar." I hope he thinks it was a step in advance!

Begging you kindly to give the above a corner in your next issue.

CAWNPORE, 16 May 1881.

I am yours faithfully, GAVIN JONES.

TUBE WELL MAKING.

(To the Editor of the Australasian.)

SIR,—As I am asked a variety of questions upon the above subject during the time I attend at the Exhibition, I will, with your permission answer the most important of them through your columns—*viz.*, how to bore a well through drift sand; and is it possible to put a tube well through brackish water to obtain fresh water further down! There is no doubt that both these objects are to be attained, and the process with my Tiffin well-boring and rock-drilling machine may be described as follows:—Set the well machine into position with the tube and well auger of the size desired. The tube is then forced down by means of a forcing-jack. Set the auger to work to take the earth out of the tube. As the work progresses, the tube is added to in two-feet length. Should clay or rock be encountered, it is then merely necessary to change the boring tool, and in this case the tool used bores as large a hole as the outside diameter of the tube, so that the tube can be forced down as before. In this way any ordinary depth can be sunk. If drift sand be met with, the tube can be driven through it, and then the sand pump must be used to take the sand out of the tube, and the work is continued in this way until water is reached. Successful wells can be sunk at from 30 to 50 feet per day, and one man and a horse are all that is necessary to do the work.

I may say that I have travelled over a large portion of the United States of America and California, and have seen a great many wells made in this way—fully nine-tenths of them being successful. A great many are less than six inches in diameter, some of which will water 10,000 to 20,000 sheep without showing any sign of exhaustion. I am quite certain that wells may be as successfully put down in the Australian colonies, and thus prove of immense value, especially to squatters who have their runs in dry districts.—Yours, &c.,

WILLIAM STEPHENS.

Victoria

WELL-IRRIGATION IN GUZERAT.

I.

(To the Editor of the Times of India.)

SIR,—I take the following few lines fom *The Indian Agriculturist* of the 2nd instant:—"In your issue of the 1st April last is published a reprint of a letter on the subject of well-irrigation in Guzerat from the *Times of India*, in which the writer makes some very sensible and pertinent remarks. The subject of well-irrigation is one that might not only engage the attention of Government but also of all those who are desirous of advancing improved agriculture." Experience has taught our Government that unwillingness to recognize the protective influence of well-irrigation is suicidal to their interests and ruinous to the agricultural prosperity of India.

The most important State business that now engages the attention and occupies the valuable time of the ruler of the Bombay Presidency, is *insignificant* when compared with matters touching life and death. In the report on the Famine of 1860-61, by the late Colonel Baird Smith, R.E., I read the following weighty remarks respecting wells:—"They rank with the greatest rivers in the extent of their influence, and it is the larger and the more universal, inasmuch as the supplies from them are accessible to almost every proprietary community, however modest its resources, or however limited its possessions. Hence the immemorial importance of that branch of artificial irrigation which is dependent on wells. A permanent well is equal to the irrigation throughout the year of nine acres, and a temporary well is equal to that of three acres. I have known many instances of from fifteen to twenty acres being brought to maturity under a large and bountifully supplied well.

I am able from personal experience to cite numerous instances in which crops had, when rainfall was scanty and deficient been taken to perfection by the aid of wells. The Hon'ble L. R. Ashburner, C.S.I., made the following official acknowledgment before the Select Committee in England in 1872:—"Irrigation does exist to a certain extent, but no doubt it is the great want of the country to extend it. It is the great object to which we must look for improvement of the country." But for the development of the resources of this rich country we require men of action. The writer referred to in the *Indian Agriculturist* advocates the introduction of wind-mills. In Guzerat we have during the hot months strong steady wind, and I have no doubt that it could be turned to very good account either by Government or by private enterprize. On the banks of our river—the Saburmattee—a very large tract of land might be usefully watered with wind-mills at a comparatively trifling cost. The water-lift taken in 1868-69 by Mr. A. A. Borradaile, late Collector of Ahmedabad, from the farm at the village of Hansole to the Broach Exhibition, where it was approved of and received a prize, raises more expeditiously a larger quantity of water—20,000lbs. per hour—than the lift invented by Major Steele, R.E.; but both these lifts are too expensive for the ordinary ryot. Our indefatigable Governor, Sir James Fergusson, might with very great advantage to the State and the impoverished tenantry of the Queen-Empress, direct without further loss of time the attention of all the Collectors in the Bombay Presidency under his control to this very important subject, and offer a suitable reward

for some very easy and inexpensive plan of raising water with celerity and in sufficiently large quantities for irrigation. Our Collector, Mr. J. B. Richey, is the right man in the right place, and any efforts he might make in this matter would, I am sure be crowned with success.

A FRIEND OF GOVT. AND THE RYOT.

CAMP AHMEDABAD, May 8th.

II.

(To the Editor of the Times of India.)

SIR,—Anent the letter on "well irrigation" in this morning's issue, it would doubtless be very satisfactory if any reliable information could be published, showing the capacities of wells in various districts, their cost, and the areas and crops irrigated therefrom; also if possible, the percentage of failures in well-sinking and the causes thereof.

Well-sinking is, however, understood to be exceedingly expensive, and is probably too risky a business for men of limited means; and it would appear to be more economical for the country to first endeavour, by bunding streams in suitable localities, to retain a greater portion of the moisture so liberally supplied by a bountiful providence than has hitherto been done.

There is an admirable work on this subject, by one Colonel Dixon I think, relating to irrigation in the Ajmere districts, which might advantageously be brought to notice at this time. In this work the author shows how he constructed the Roopana Weir in Mhairwarra, 522 feet long, of earth with lime masonry, at a cost of, I believe, Rs. 2,205, and which, thrown across a gorge in a low range of hills, closes a watercourse which drains a wide range of country. There are many other such works, small and great, reported on in this work; and there are doubtless many districts in India where similar works might be inexpensively constructed. It would, therefore, seem worth while for Government to either largely undertake these minor works, or to encourage their construction by private enterprise; not only as a present amelioration of the state of the "rigorously taxed" Bhagoo, but as a reproductive work which will greatly enhance the value of lands now regarded as waste.

F. S.

My friend in the Guzerat quarter,
Whose hobby it seems is to find
A cheap way of raising the water—
I trust not of raising the wind!
The way which seems most inexpensive,
Whose excellence ev'ry one sees,
Being work'd on a scale most extensive,
Is the way the sap rises in trees!

EN ROUTE.

THE WINDMILL.

(To the Editor of the Indian Agriculturist.)

SIR,—In the *Agriculturist* of the 1st March last, page 64, on the subject of Aloe fibre, I was agreeably surprised in reading that part relating to the value of "wind-mills" as a motive-power in India.

It is no doubt quite true, that in many parts of India, the labourer can be hired at such a wretched low rate, that in many instances, machinery cannot compete with it, as for instance, in some parts of Behar, a man will bring a pair of bullocks, and a boy, together with bucket and rope, beginning work at 7 A.M., and continuing till 11, and beginning again at 3 P.M., and ending at 6. This in the hot season, and that at the rate of six annas a day. When working for himself during the hot season, he does so during the night, and a weary piece of work it is especially when one comes to think of the wretched condition of men and cattle.

Is it not surprising that no effort has hitherto been made by agricultural societies to offer prizes for the best wind-mills, or that European planters have not on their own account, long since used the winds that blow so regular into their service? They cannot plead the want of knowledge, or means, as the natives in many instances can do. What then can be the reason of this utter neglect of one of Nature's most bountiful gifts, to irrigate your fields, thrush and winnow your grain, grind the corn into flour and grind your sugar-cane? These being only a few of the benefits obtained.

I have only seen one wind-mill in India, and that was set up by Henery Chamier, Esq. in Grundey, Madras. The owner was quite proud of it, but after he left India, the mill ceased working.

However it is to be hoped, that this subject will be taken up in earnests, by those who have the means, and the time to do so, when others will follow the example when they see the advantage to be gained by doing so, and as India has now to compete with powerful, intelligent and enterprising rivals, the sooner she follows their example the less will be her difficulties in the race of competition against her.

OBSERVER.

WORMS IN CALVES.

TO THE EDITOR.

SIR,—Can any of your readers tell me the cure for worms in calves? The calves attacked are generally those dropped in the winter months, and the worms are similar to the "Lumbrici" found in horses. I have cured horses in the tartarised antimony, but am afraid to try it on calves of one month.

If any of your readers can give me a cure, please let them state the dose of the drug recommended for each month of age.

KUMAON.

THE INDIAN GOVERNMENT EXPORTS OF CINCHONA BARK.

(To the Editor of the Colonies and India.)

SIR,—In reply to "Indicus'" letter of the 24th ultimo, I would state—

First.—The Indian Government created their plantations for the benefit of the masses of the people, and to bring a cheap febrifuge within their reach and the whole of the bark ought now to be worked up in India for the benefit of the people, and not shipped for sale here for the purpose of showing flourishing accounts. To talk of a surplus of bark with millions of fevered wretches in India too poor to buy it is bitter irony, as the native press will doubtless show. The shipments are wrong morally and are wrong legally, for by everlasting laws the inhabitants of a country have the first claim upon the produce of the soil, and in the present case the produce is raised from their own taxes.

Secondly.—I have it from the highest authorities that all the capital outlay with interests has been recovered.

Thirdly.—If the Government wish to be prepared for the emergency mentioned, selling their bark in London is in direct opposition. Better let the trees grow and improve until they are wanted or store their febrifuge until required, if they will not distribute it to the poor ryots; but they need not now fear any emergency, as there cannot be much under fifty thousand acres, containing many millions of cinchona trees, planted by private enterprise in India and Ceylon,

I am, yours &c.,

THOMAS DICKSON.

123, Bishopsgate-street Within, London, April 2.

WHY COFFEE DOES NOT PAY.

(To the Editor of the Madras Mail.)

SIR,—The season here has been most favourable all around for the coming crop. "All the blossom that was out a few days ago has "set," and the little berries are "swelling" fast. They are showing well now, and with the fine showers we have had lately, will be out very soon; so on the whole "crop prospects" are good, and in some places even "bumpers" may be looked forward to. But still, with everything so favourable before us, and after all the inferior working of estates for the past three or four years (on account of short crops), proprietors still hold back from coffee, and are "plunging headlong," into "gold." Coffee is not looked at, coffee is nothing now, although so long as estates were worked properly, they did pay, and still will do so if worked by experienced superintendents. In days gone by, coffee did give good, very good returns, and the price was nothing to what we get now, and yet coffee does not pay now! For this simple reason, that the old hands, experienced men, are kicked out, and replaced by men who can be got on Rs. 100 or Rs. 250 a month; young and inexperienced, and who have perhaps never seen a coffee tree, and know no more about how to go to work than a frog. I grant there are many young men who do their best, and try and pick up things from other planters; but the consequence is, estates suffer, crops are short, and coffee gets a bad name. As time goes on, crops in Wynaad will still grow less, yet it is not the season that has to do with it, but the working. There are many who, although having an interest in the gold fields, hold to coffee, working hard at it. All can't turn up "trumps" in the "gold mania," and as far as I am concerned, I think it a myth with the exception of a few places.

ALLY.

S. Wynaad.

CINNAMON CULTIVATION IN THE HILL AND LOW DISTRICTS.

(To the Editor of the Ceylon Observer.)

DEAR SIR,—During the last few years planters, owing to the short ness of coffee crops, have given their attention to what is called new products. Amongst other things attention has been turned to cinnamon

cultivation. A very great error has been made in cultivating this product. Plants have been put out singly on one estate in the hill country on which I was resident. The visiting agent, on one of his inspecting visits, suggested a field on which the coffee had gone out, to be planted with cinnamon, I was asked to make inquiries in the low-country as to cost of plants. Clumps of plants were then selling at Rs. 30 per thousand; that was considered too high, and my P. D. who was resident on the adjoining estate, during one of his frequent visits to Ambagamuwa, purchased plants at Rs. 10 the thousand and planted them out singly, one in each hole. When next I met him, I pointed out to him the great mistake he had made. The plants would, I said, be fit for cutting in about three years. Each stock would then put out a couple or so of suckers which in their turn will be fit for cutting in a couple of years. The clumps or bushes will thus be gradually pruned, and it would take ten or twelve years before the cinnamon will pay more than the cost of monthly weeding. My P. D. looked surprised and asked me why I hadn't told him so before. For the simple reason, I answered, that he had not consulted me. I have written so much, as I see from time to time advertisements of cinnamon plants for sale, and as a warning to planters not to put out plants singly. It will never pay, especially as the quality of the cinnamon grown on the hills is inferior and is known as Corle cinnamon. The best use to which such cinnamon can be put, is to have it scraped into chips and sold for the extraction of oil. Cinnamón seeds are generally sown in the low country, in beds in which drills are made with the hand, and into which from 10 or 12 to a handful of seed is dropped. The more the seed the larger the clump, the sooner it will pay and the chances of the plants growing, as the outer ones protect the inner ones. It has been said in an old number of your Directory, in an article written evidently by that very able planter who now writes from the "Western Province," that it is next to impossible to make supplies good on our old estates. If the writer of the article in question were to visit the estate under Mr. Drieberg's charge at Ekelle, he would no doubt be agreeably surprised to see acres and acres of supplies flourishing, by Mr. Drieberg sowing his seed in handfuls in drills. Finally it will be impossible for planters up-country to put out plants in clumps, unless from nurseries on the estate, as the cost of carriage of so much soil with the clump will be ruinous.—Truly yours,

B.

VEYANGODA, April 24.

The Indian Agriculturist.

CALCUTTA, JUNE 1, 1881.

CANE-CRUSHING MILLS.

Communicated.

IN January last I was requested by the Deputy Commissioner to test the working of the small sugar mill, and compare its results with those of a native machine or "Behea," a small plot of standing canes measuring 2 kanals (·181 of an acre) was purchased in the Raqba of Premgharh, near Hushiarpur civil station, and the mill sent down to the village and set up alongside a native Behea. A few bundles of stripped canes were provided, and at 1 P.M. punctually we set to work, at 2 P.M. both machines were stopped and progress reported.

Native mill had turned out in	1 hour	1 maund	10	seers.
Calcutta mill	ditto	ditto	20	do.

This was not re-assuring, and the results were not as good as I anticipated, however after a few minutes' rest I thought I would work at full pressure, I was determined not to be beaten, so I tightened up the "cotters" C. C. with most satisfactory results, and found that in 45 minutes I had got into the earthen pipkin 20 seers of juice, whereas the native mill did not after working its full hour, manage to get more than the 1 maund and 10 seers as before.

I could have done even better than this, but I did not wish to run the risk of an ignominious break down before the whole village. The Calcutta mill was purchased about 8 or 9 years ago, The frame work was shakey, and the bolt marked B in the drawing was *minus* its "nut," the consequence being that the whole affair creaked and swayed in a most ominous manner at times: I felt I was testing it too severely, so had to loosen the "cotters," or as I before said a break down might have resulted, and that would never have done before the sceptical and mildly sarcastic lookers on.

The description of cane used was the species known locally as "Dhaula."

The next day January 7th, I made another trial, results as before.
Native mill, 1 maund 10 seers in one hour.
Calcutta mill, 20 seers in 45 minutes.

The question of cost of operation and relative performance has now to be considered. Taking the unit of performance as the amount turned out in a working day of 8 hours, we have—

From native mill.

	Rs.	A.	P.
1·25 × 8 = 10·00 maunds at a cost of— ...			
8 Pairs of bullocks @ 8 as. per pair ...	4	0	0
3 men @ 2·5 as. each	0	7	6
	4	7	6

From Calcutta mill—

$\frac{60\times8}{45}\times20=10{\cdot}66\times5=5{\cdot}33$ maunds at a cost of—

	Rs.	A.	P.
1 Pair of bullocks @ 8 as. = ...	0	8	0
3 Men @ 2·5 as.	0	7	6
	0	15	6

Calculating a month's outturn, we have from Behea 300 maunds at a cost of Rs. 135.

From Calcutta mill, 160 maunds @ Rs. 30 per cent. in favor of the latter.

The rollers of our mill are iron, and framing of sál wood, brass bearings.

A mill with horizontal rollers would give infinitely better result. The mill should be on a carriage mounted on wheels removable at pleasure. The rollers to be about 1' in diameter and from 2' 5" to 3' long, and propelled by belting, a machine of this description, should easily express 40 to 45 maunds of juice per diem, if not more, and its working daily expenses need not exceed Re. 1-5.

The native Behea seldom extracts more than 50 per cent., whereas our European machines extract 70 to 80 per cent. of juice. In the eyes of the natives our machines have one serious defect, they crush the pachki or megass to shreds in such a manner that it cannot be utilized for inferior cordage or "twist" for mats. Theoretically they are wrong and have, I maintain *no right* to turn their megass into rope, they should use it as fuel underneath their coppers or "taiche" and return the ash as manure to the soil. This they will not do unfortunately for themselves.

Such a machine as I have suggested above might easily be turned out for Rs. 700, and should turn out 50 maunds of juice per day, or about 1,500 maunds of juice per mensem, and allowing the acre to yield under *native cultivation* 250 maunds of juice, this mill would deal with 6 acres per mensem, but working as the natives sometimes do, 12 to 14 hours out of the 24, would suffice, for say 10 acres per mensem. Sugar cultivation will never be fostered and devolped until we see dotted over the face of the country a few score factories or "Usines" like the one now at work at Shahjehanpur, N.-W. P. If instead of investing their hard-earned money in scandalously rotten concerns, and the loans floated for the sole benefit of bankrupt states such as Peru, Spain, Turkey, Mexico, and South American Republics, the Englishmen at home turned their attention to their country and endeavoured to develope its staples, they would find if not a rentable El Dorado, at least a field for enterprise which would speedily reward them to an extent beyond their most sanguine anticipation.

AGRICULTURE IN MADRAS.

THE Madras Administration Report for 1879-80 has come to hand, and contains a vast fund of entertaining reading. This report is always well written, and a well written book on almost any subject, is worth reading, but the Madras Government, from the interest they take in agriculture, cannot fail to produce an interesting book. The very get up is superior, and is quite equal to what one would expect from an English book-binder.

The total area of Madras under assessment is 57,905,722 acres —and under the general classification of crops the land under crop was as follows:—

	Acres
Cereals	16,441,323
Pulses	1,613,514
Garden produce	580,798
Drugs	156,886
Spices	200,905
Starches	15,096
Sugar	58,977
Oilseed	983,221
Dyes	244,969
Fibres	1,162,671
Total	21,457,800

This accounts for not much over one-third of the land, the whole details of which are as follows :—

	Acres	Percentage
Cultivated	20,014,090	34
Cultivable but not cultivated ...	17,808,282	31
Pasture and Forest	6,286,444	11
Uncultivable	13,796,906	24
Total	57,905,722	

Here then is an answer at once to those who say that India is too densely populated. Here we have 31 per cent. of cultivable land uncultivated, besides 24 per cent. of what is called "unculturable." That is to say, it is not adapted for annual cropping, but the most of it is well adapted for forest growth, and this is a matter which does not in India receive the attention it deserves. In Scotland vast stretches of land were put under forest 20, 30, or 50 years ago, and the landlords are finding the experiment exceedingly profitable, more so in many cases, than if the land had been suitable for cereals, and had been let out for that purpose. The population of the Madras Presidency is about 32 milllons, and the gross area 138,856 miles, shewing a density in population of 230 to the square mile, while Oudh supports 468, and the average all over India is 210.

With regard to the quantity of grain produced, we are left entirely in the dark, except the slight information to the effect that the crop was a ten-anna one. The average is assumed to be a twelve-anna crop, hence in the year under notice, it was five-sixths of the average.

The prices of grain were of course much lower than in the two previous years, when famine prices ruled, but they have not yet sunk to the normal range which ruled before the famine.

The following table shows at a glance the ruling rates for the past five years, the rates are in seers (of 80 tolahs) for rupee :—

	1875-76.	1876-77.	1877-78.	1878-79.	1879-80.
Rice ...	16·0	11·8	8·1	9·1	12·5
Paddy ...	28·6	20·4	13·6	15·7	21·8
Cholum ...	26·6	19·8	11·1	13·1	19·9
Cumbu ...	26·4	18·1	11·3	14·4	20·6
Ragi ...	27·9	19·4	11·1	14·2	20·8
Varagu ...	39·6	28·2	15·8	19·0	26·5
Wheat ...	11·4	9·7	6·5	5·9	6·2
Salt ...	15·8	15·0	11·2	11·9	11·9

This is in conformity with ordinary experience, for when, from any abnormal cause, prices rule exceptionally high, they very seldom fall back to their original level. The prices of labour did not vary much, and this is all the more noticeable in Madras, where a large proportion of wages is paid in kind. Before looking at what the Government have been doing in this way—for this corporate body is an extensive farmer—we shall have a still closer glance at the condition of the rayat. The area under cotton was 95,465 acres or 7·8 per cent. over the previous year, and here we begin to miss the information as to the quantity produced. We should liked to have know the outturn per acre. It is quite impossible to compare one year with another, when only the number of acres under crop are given, and the only clue given to the produce is to be found in a comparison of the prices of grain in the past few years. This at best is a clumsy estimate, because other causes than the quantities produced, go to influence the prices. A scarcity in another part of India is sure to raise rates, and although there has been no scarcity in any portion of the country during the year under notice, an abormal demand may have existed for Ceylon, Mauritius, or China. It would be much more satisfactory if the outturn per acre could be arrived at, and we think this could be done without much extra cost or trouble.

In the Government department, we find more details given, and it is perhaps natural that this should be so, the majority of such operations being under the charge of Europeans. The greatest attention has been given to agricultural education, especially at Saidapet. So far as it is possible to know, much good work has been done, and it is to be hoped that the lessons learned there by the native youths, may not be forgotten when these students return to their villages. We confess, however, that we have not much faith in the earnestness of the students. They seem more anxious to have some complimentary letters pinned to the end of their names, and from this we suspect those youths will be much too grand to take to agricultural pursuits at home.

Several experiments were made with different manures, cattle-box manure having been found useful. The providing of manures for their crops is quite beyond the ability of the rayats. Our agricultural reformers however, will not see this, and hence these annual experiments, which all go to prove, that if the rayat will only put ten rupees' worth of manure on each acre he sows, he would realize a large margin of profit. This may be perfectly true, but they may as well tell the rayat to expend a thousand rupees per acre, so far as their ability to carry out the recommendation is concerned. What we want—and we are almost tired of pointing out this—is an implement which will turn up two or three inches of the virgin subsoil. Manure might then be largely dispensed with. This plough need not cost more than from five to six rupees, and a small expenditure in this direction would soon tend to add fifty per cent. to the outturn of crops.

The Government cinchona plantations have had a very favorable year, the production of bark having amounted to 179,299lbs., and the profit made Rs. 2,61,091. We cannot resist the opportunity of drawing attention here to this fact. The object of the Government in opening out these plantations, was to give the new industry a fairer trial than it could have had under private management, where capital might possibly be scanty. On this subject, the Administration Report for 1874-75 says :—"As yet cinchona cultivation has not proved attractive "to planters, who generally believe that the crop is too much "of a speculation." It has now entirely passed that experimental stage, as is proved by the profit realized by the Government. This has been as follows :—

1876-77	Rs.	48,920
1877-78	„	2,88,980
1878-79	„	3,32,535
1879-80	„	2,64,091

Under these circumstances, we maintain that the time has come for the Government to withdraw from the work, and leave it in the hands of private enterprize, as was done in the matter of tea.

EDITORIAL NOTES.

A JUNIOR or first class school has been formed in the School of Agriculture at Sydapet, the attendance being rather small—only ten boys. It, is believed that many boys will be induced shortly to join this elementary class.

THERE are in the United States 727 paper mills, making 1,800 tons a day of all kinds of paper; but the writing paper used is not less than 200 tons daily; half of which is manufactured at Holyoak.

THE Madras Government have forwarded to the Secretary of State a case containing samples of the gums and resins of the forests in this presidency. These specimens have been collected by the museum and forest authorities, and are being sent for analysis to a London chemist.

THE Dominion House of Commons has passed a resolution to encourage the manufacture of beetroot sugar, by exempting all made in the Colony from excise duty for a period of eight years. We doubt much this effecting the object of establishing the manufacture.

CALIFORNIAN vines are so prolific that at no distant date they may be expected to compete with those of the old world. France supplies the deficiency in its own production by importations from Spain and Italy, and even Californian wines are brought to Bordeaux, there transformed and re-exported to the country of production under a French brand.

A SMALL consignment of two tons of Egyptian cotton has been brought by the P. and O. S.S. *Mirzapore*. As it is a very fine, soft, and long staple cotton, it has been procured by one of the spinning companies in Madras, as an experiment, to see if it is possible to spin the finer and more expensive descriptions of yarn, which at present have to be obtained from England.

THE Royal Commission on Agriculture is now sitting four times a week in London. The Commissioners have taken the evidence of landlords and of agents and are at the present time completing the evidence forthcoming from tenant farmers. They propose to take the evidence of labourers, and so present a full view of the question.

THE complaints that are now made against the way the Tramway ill-uses and smashes up baggage and goods in transit, and the total indifference of the Company to complaints and claims for compensation, are far louder and deeper than anything we ever heard in days gone by, when baggage and goods had to be brought the long journey *vid* Caragola in rough country carts and over the many difficulties of that route.

MR. P. T. SLEMA LEBBE has been good enough to send us a bunch of grapes the produce of his cultivation which was referred to in a paragraph in the *Jaffna Patriot*, copied into our issue of last evening. He informs us that the bower yielded over 120 lbs. Having tasted the grapes, we can testify that in the present hot weather they are very refreshing. The bunch sent us is six inches long, and weighs 7 oz.

A GENTLEMAN who has made great use of salt in growing onions, and who has been very successful, informs us that he has used as much as two barrels to the acre. He thinks that the salt adds to the growth of the onions, weakens the growth of weeds, and is very beneficial in warding off the attacks of noxious insects, but thinks that a sufficiency of salt to kill grubs and wire-worms would also kill vegetable life generally.

THE late enhancement of freights on the G. I. P. Railway is said to have already begun to produc the evil effect predicted for it, namely, a diminue tion in the flow of traffic of grain, and other up-country produce, to Bombay. Even under ordinary circumstances, the cost of conveying a ton of whea from the Central Provinces to the sea coast it very little, if at all, below the cost of transis from Chicago to Liverpool.

THE Hon'ble V. Ramyengar, C.S.I., Dewan of Travancore, was a Alleppey lately to witness the Cardamom sales, and returned to Trevandrum on Monday evening. We are sorry to hear that the proceeds of the sale this year are much below those of the previous year, and considering that Cardamom constitutes an important factor in the public revenue of Travancore, it is much to be regretted that there should be any decrease in the revenue under this item.

CONSIDERABLE annoyance has been caused to Messrs. Thomson and Mylne, on account of a printer's slip in our May issue. In the article on "Sugar-cane," in the paragraph commencing "It is not only" the "*Beina*" machine, appears as the "*Beheea*" machine. We are sorry that this has occurred, and would take the opportunity of pointing out the necessity of plain clear writing, the reverse of which is often the cause of such mistakes.

A CORRESPONDENT *Observer* touches a very important subject, that of wind mills. For irrigation purposes they are invaluable. He asks why they are not used. One objection to them is, that as there might be no wind when the farmer wished to raise water, it becomes absolutely necessary that each wind-mill must be supplemented by a tank of storage purposes, and as large quantities of water permeate through the soil, this tank must be *pucca*. This we fear is the great objection.

WE in India stand no chance with America in the matter of cheap communication. We have previously referred to this subject in so far as it operated against the Indian wheat trade, showing that on the East Indian Line grain is carried at a shade over one-half penny per ton per mile for long distances—the correct figure is ·547*d*.—while in America the rate is under a farthing. From the following extract from an American paper it will be seen that minerals are carried at marvellously low rates.

THE climate of Chili is very favourable to bees. Wax of a good yellow colour, without odour, and other kinds fit for candles are produced. The exports in 1870 were 134,511 kilos., value 121,058 pesos=605, 290 frs., and in 1874,98,087 kilos., value 83, 779 pesos. Of honey the shipments from Valparaiso were in 1870, 571,848 litres, value 114,368 dols.=571,840 frs., and in 1874, 1,384,844 kilos., value 207,871 pesos=1,039,355 frs.

There were in 1875 89,067 hives known, the principal number of which were in the provinces of Santiago and Colchagua.

FROST kills watercresses. When they are fast rooted and flourishing in a brook or any other water; it will be found that after a coat of stout ice has been formed, the crop is entirely gone. To preserve cresses out of doors, shelter of some kind is necessary. It is not unusual for the market-growers to let in a flood of fresh water when a sharp frost is expected. This covers the plants and the ice formed so far above them that they escape its effects. Another plan is to lay planks or tree loppings over the bed. Where it happens to be convenient, a frame is the best protection.

WE (*C. & M. Gazette*) are glad to hear that the experiments which have been conducted in the Chumba State in the cultivation of hops, and the introduction of silk-worms, promise to be successful. Of the hops planted in various parts of the State, it was found that the English sorts did exceedingly well in Panji alone; but the Bavarian and French hops grew satisfactorily in most parts of the State. The silk industry quite fulfilled the expectations of the Superintendent of the State, who expects that it will now be taken up by the zemindars, as they have seen that it is likely to be profitable.

SOME time ago Mr. J. H. Angas supplied the manager of the Government Experimental Farm at Cashel, in Victoria, with a bag of his celebrated Hill River Purple Straw wheat, which took the £50 Challenge Cup last year in Adelaide. In reference thereto this gentleman wrote him on March 29 as follows:—"You will be pleased to learn that the wheat grown from seed procured from you last year has obtained the highest honour at the Exhibition, weighing 68½lb. per bushel, and also btained Messrs. R. Goldsbrough & Co.'s Cup, va lue 40 guineas, for the best twenty sacks of wheat grown in the North-East division of Victoria, weight 67lbs. Since weighted, and found the former is correct —real weight 68lbs. 4¾ oz. per bushel."

THE monsoon rains of the year 1880 varied very much in quantity in the several districts of the North-Western Provinces. In the upper districts lying under the Himalayas the rainfall was plentiful in June and July, but insufficient during August and the first half of September, and the season closed with extraordinarily heavy rain and destructive floods in the middle of September. In the lower part of the Doab there was short rainfall from the beginning of August, which in the districts of Agra, Etawah, Cawnpore and Bundelkhund, ended in an almost complete drought and failure of the unirrigated *kharif* harvest. Indeed, some other districts such as Muttra, Aligarh, and Etah, were only saved from the same fate by receiving a portion of the heavy rain which fell higher up the country in September.

COAL has been put into New Orleans from Pittsburg, 2,000 miles at 60 cents. per ton, and the average rate does not exceed 85 cents. making less than one-third to five-twelths of a cent. per ton per mile. The lower rate would be 1·8 cents. per bushel for carrying wheat the same distance. Railroads carrying wheat from St. Louis to New York 1,200 miles, now charge 23 cents. per bushel, or at the rate of 38½ cents. per bushel, if carried 2,000 miles.

That is to say the average rate is ·21*d*. per ton per mile, while in some instances it has been carried at '16, now on the East Indian Line, the principal coal line of India, the charge from say 748 miles at the rate of 603*d*. per ton per mile or 187 per cent. higher than the average rate in America.

ATTENTION is now being directed towards fibrous plants in this island. The aloe (*Agave*) fibre is already exported to a certain extent and of good quality. The *rhea* fibre (*Boehmeria nivea*) has been cultivated with success, but the difficulty of extracting its beautiful fibre has discouraged its promoters. It is re-

ported lately that a chemist in the neighbouring French colony of Réunion, M. Reynaud, has discovered a process for obtaining at a trifling cost, the fibre not only of the rhea but of the aloe and all other textile plants. If such is the case, a new era will be opened to an important class of industries. The statement is, however, questionable, seeing that the *rhea* is a bark fibre, and the aloe an interior fibre.

RAINWATER brings down yearly about 12 pounds of ammonia per acre of ground. To supply an equal amount of sulphate of ammonia, at six cents. per pound, would cost the farmer $2·80 per acre, and is, therefore, the manurial value of the rain. This refers to America where the rainfall is about 38 inches per annum. Here in India it is twice that quantity, so that each year's rainfall, supplies ammonia to the land at the rate of twenty-four pounds per acre. The question for us to consider is, how much of this valuable manurial agent reaches the soil, and how much is simply carried off to the sea by floods. When the time comes that we have subsoil drainage, we may expect the soil to be able to retain the large portion of this valuable material.

THE Province of Amazonas, Brazil, exported last year nearly 200 tons of sarsaparilla root. The vine, which is believed to be *Smilax papyracea*, grows in the swamps in a kind of rich, black muck or mud, and the collectors often spend weeks in these marshy pools. The roots are traced and raised with a sharp stick, but the vine or creeper is not disturbed, the roots being cut off near the stalk, which is covered up with a little earth, so that fresh roots many grow and in time a fresh harvest be gathered. Two or three pounds are produced by a single vine. The quantity used in this country alone is said to exceed 120,000 pounds. Attempts have been made from time to time in different countries to cultivate the plant, and they will doubtless ultimately be successful; but several years are required to produce plants with good roots.

MR. ROBERTSON, of the Government Farms, Madras, submitted lately to the Board of Revenue a report on the experimental cultivation of Madagascar paddy which he considers the home of the Carolina species. The product of the experimental cultivation of this variety of rice appears to the Board of Revenue to be of superior quality, and if Mr. Robertson's present opinion, that it thrives with a quantity of water less than the indigenous varieties should be confirmed by further experience, the result should be of great value to localities where the railfall is scanty and water not always abundant. The samples received by the Board will be forwarded to the Chamber of Commerce, whose opinion the Government would be glad of both as to the article itself and upon the suggestion to send the grain and rice to London for valuation. 48lbs. of seed sown on the 20th September 1880 yielded on 2nd February 1881, 1,483lbs. grain, and 2,436lbs. straw.

THE cultivation of cardamoms is, according to Mr. Markham, carried on to a great extent on the western slopes of the Coorg Mountains. In the month of February, the Coorgs start from their villages, and arriving on the mountain slopes, select one of the largest trees, giving a preference to those on a western or northern slope. Around this selected tree they raise a platform and commence to fell it. In felling it, they take care that it shall fall towards the base of the slope, and thus, in its fall, carry all before it. Having cleared a space of some 300ft. long by 40ft., broad and freed it from all brushwood, they commence planting. In three months the plants begin to appear; after about 20 months the plants have reached a height of five feet, and in six months later, that is 26 months after the first sowing, the first clusters of flowers begin to appear. During this period the ground is kept constantly cleared of all weeds. Six months (October) after flowering, the first crop is ready for picking, but a full crop is not obtained till the following year. These plantations are kept up for six or seven years, when the soil having become exhausted, fresh ground is again cleared. The harvesting is attended with some amount of suffering, as the grass which springs up around the cardamom plants cuts like a knife, and large leeches are very abundant. The capsules, when picked, are packed in bags and carried to the villages, a distance, frequently, of ten to twelve miles. Some families have been known to collect cardamoms to the value of Rs. 600 to 1,000 per annum.

"WE hear that it is in contemplation by the Dewan to import a windmill from Europe to work the wells in the Rajmehal on the High Ground. We trust that the report is true as such an example would have a good effect on the ryots. The superior advantages of windmills for working pumps have been demonstrated long ago, and we believe they have been introduced into other parts of the country." This paragraph we have extraced from the *Bangalore Spectator*. The introduction of windmill is a subject of more importance than at first sight appears. It being now generally admitted on all hands that well irrigation is better suited to India than is canal irrigation, provided the cost of raising the water could be brought within reasonable limits. The windmill seems to us to promise this saving. The only drawbacks to its introduction is its cost, and the necessity for it to have the accompaniment of a *pucca* tank. These furnished, the subsequent supply of water can be had at a nominal cost. The cost of the apparatus itself is not so very much, but the outlay necessary for a tank will be considerable. The necessity for having a tank will be seen at a glance when we remember that it would frequently happen that there might be no wind at the very time the farmer wanted to raise water, and besides the supplying of water to several fields simultaneously would demand a larger delivery than was perhaps available. Hence the extreme importance of storing a larger supply, and to neutralise the effects of percolation, all storage tanks would have to be *pucca*. We are making inquiry into the cost and efficiency of windmills, and will shortly be in a position to speak definitely on the subject.

THE improving of our cattle is a subject on which much has been said and written, the only remedy suggested has been the introduction of a better class of breeding stock. Granting the advantages certain to accrue from this, we cannot shut our eyes to the fact that even if our cattle were improved by that means, deterioration would immediately commence on account of the miserable class of food we give them.

It never seems to have occurred to the Indian farmer, that if he keeps cattle, he must feed them. The custom in force in India is to allow these unfortunate animals to eat whatever may not happen to be of any value, and they are generally supposed to pick up their living as they can, outside of working hours, at a time when under better arrangements, they would be resting. Crops are never grown here, with a view to provide cattle food. At home this is an important item of a farmer's duty to see to the providing of a plentiful supply of nourishing food—both green and dry—for his cattle. In another column will be found an article detailing certain experiments made in growing turnips with various manures. An acre treated with 5½ cwt. of dissolved bones and ½ a cwt of sulphate of potash, produced 15 tons 6 cwts of turnips, reduced to Indian weights for purposes of comparison, we find this to be 417 maunds 11 seers. The produce of this one acre would suffice to give 15 animals three seers each daily all the year round.

The cost of this manure was about £3 per acre, consequently a farmer could give 6lbs. of turnips daily to a cow, at a cost per annum of four shillings. This of course is over and above the ordinary cost of raising such crops. Still it seems worth our notice.

IN a thoughtful article on the anticipated changes in regard to our opium monopoly, the *Indian Herald* remarks:—"The scheme, as far as is yet known, is intended to abolish the system existing in Behar and Benares, and of which Patna and Ghazipore are the centres, and to assimilate it to that of Malwa, where the opium is produced by the subjects of native princes. By our present system we directly supervise the growth of the poppy and the manufacture of opium, binding the ryots to sow the needful amount of land, and receiving the entire produce at certain fixed prices. The opium is eventually sold by public auction to the Calcutta merchants, by whom it is shipped to China. We understand that it is now proposed to withdraw from this immediate connection with the trade, and to establish a thorough system of customs' control, without relinquishing the right of regulating the quality of opium produced. One immediate effect of the proposed

scheme, the details of which may be looked for before long, will be the dissolution of the present opium establishment, but doubtless some provision will be made for the officials who are thus likely to be deprived of their means of livelihood. The scheme, as a whole, if designed for the purpose of merely disguising our connection with the opium trade, must be condemned, whether it entails loss of revenue or not. But on the other hand, it may be the intention of the Government to bring about changes of a beneficial character in the administration—changes which accidentally harmonise with the wishes of the scrupulous coterie at home. The Government is certainly entitled to the benefit of the doubt, and until we know something more of the matter, it is premature, to say the least of it, to mumble accusations of dissembling and hypocrisy."

MR. P. DE LAVAL LENNOX, of the Bhawarna tea estate, in the Kangra valley, has contributed to the *Journal of the Agri-Horticultural Society of India*, a very valuable paper on cattle-disease in the district of Kangra, its treatment and its remedy. Mr. Lennox's specific is simple enough—the leaves of the *Potentilla*, or wild strawberry, pounded into a pulp and given as a bolus. Previous to the use of this remedy a beast seized with the cattle-disease, as it appears in the Kangra district, almost invariably died. The symptoms of the disease were, listlessness and refusal of food, flabbiness of the ears, flowing of mucous saliva, loosening of the teeth, aguish shiverings, excessive relaxation of the bowels, increasing till accompanied by blood, and generally ending in death. Mr. Lennox lets the disease run its course until four or five evacuations have occurred, and then gives a bolus, about the size of a hen's egg, of pounded strawberry leaves, repeating the dose every three hours until the beast recovers. Under this system only one animal has been lost out of a large number so treated, and as the *Potentilla* is obtainable anywhere along the Himalayas at a height of from 3,000 to 4,000 feet, and also along the banks of irrigation canals and other moist, but not wet or damp places, and as it costs nothing beyond the trouble of gathering, the value of the remedy is immense, and we should imagine that it would prove efficacious in cases of dysentery in the human subject. Mr. Lennox is ready to send dried (pressed) specimens to any one wishing to identify the plant and give it a trial. The *Potentilla Tormentilla* was, it is believed, used by the ancient Greeks for the cure of colic, diarrhœa, and dysentery. The natives of the Kangra valley, who are constantly going to Mr. Lennox to be shown the plant and instructed in its use, tell him that where this remedy is used at the proper time, it not only cures the cattle at one homestead, but prevents the pread of the disease.

IT is difficult, we fear, to induce tea investors to believe that the recent improvements in the London markets is other than transient, but such as will sit down and fairly study the prospects of the trade or business in its entirety, will we think arrive at no other conclusion than that tea has reached its normal value, and to look for the prices that ruled during the prosperous years from 1874 to 1876 is a hopeless delusion. That small parcels of full flavoured high class teas suitable for mixing (such as Pekoe and Broken Pekoe) will command an average of eighteenpence, may reasonably be reckoned on, but that it will not pay to make these brands alone is equally certain; and we again counsel all concerned in the industry to grapple honestly with the real difficulty that renders tea planting, at the present day, a hazardous enterprise, and one that, unless prompt measures are taken, will speedily prove it a hopeless one. Were agents and managers to work loyally together, there can be little doubt that their combined views would meet with attention, but at present neither the Government nor the moneyd public can precisely understand in what way assistance is required, the reports on the Labor Commission not having resulted in bringing about that unanimity that sanguine people expected. At the risk of wearying our readers, we repeat what has so frequently been urged in our columns, that the only hope of tea planters ever being able to compete with their Chinese rivals is to put down their teas in London at a similar value, and unless they make up their minds to do so, none but those who can keep their heads above water during this, the critical, season will pull through. That planters with capital to back them will survive we can fully understand, and possibly when their less fortunate competitors are compelled to abandon the enterprise, the smaller quantity turned out may, for a time, tend to keep up the price of Indian tea; but under these circumstances all hopes of introducing it direct to the general public, unadulterated, upon which success ultimately depends, must end, as the comparatively small parcels brought forward will be bought up at auction by dealers solely for mixing purposes. Tea has as fair a field before it as any commercial undertaking that has ever been brought forward in this country, and all the drawbacks to success—the bonus, want of inter-communication, jealousy among planters, famine rates for provisions, difficulty in procuring labor,—rest on one common requirement, which is railway communication; and unless that is provided out, fully two-thirds of the gardens must be abandoned. There is no use in blinking the question; all who are competent to form an opinion on the subject are convinced of it. It may be argued, by many, that the Railway from Daudkandy could not be made under two or three years, and what is the impecunious planter to do meanwhile? The reply to this is that capitalists will come forward to tide those over the period whose properties are really worth keeping up. Lest this assertion should give rise to anticipations on the part of those who may possibly imagine they see a chance of saddling the mortgagors with their plantations in a manner similar to that in which certain individuals served the Land Mortgage Bank some sixteen years since, it may be as well to mention that the draft articles of association provide against such a contingency, and moreover the Syndicate will not be prepared to advance on any but first class properties and those whose title-deeds will bear the strictest scrutiny. First class properties do not necessarily mean the acme of desirability in tea holding, such as an undulating plain planted with Munipoorie indigenous, although such will of course more readily command support; but we believe we may confidently assert that properties whose only drawback is pure impecuniosity will not lack a helping hand. Meantime, although traffic statistics will have to be collected in a systematic manner, tea planters on the line of route of the proposed railway may, even at this early stage of the proceedings, render material assistance, approximately estimating the amount of traffic both in goods and passengers that passes their doors upwards and downwards.

OFFICIAL PAPERS.

MEMORANDUM ON THE ADMINISTRATION OF THE NAGA HILLS DISTRICT.

WE make a few extracts from this memorandum :—

Conservancy of forest round Kohima.

18. Nothing has yet been done in the matter of forest conservancy and the subject requires careful consideration. The Conservator will be requested to visit Kohima after the rains, and to prepare a report, showing how much country round that station ought to be preserved (1) for timber for building purposes, (2) for firewood and grass. Meanwhile, the Political Officer should put a stop to all clearances, firing of the jungle, and *jhúming* within a moderate radius of (say) five miles round the station.

Extent to which *jhúming* is practised.

19. With regard to *jhúming*, or destruction of forest for purposes of temporary cultivation, the practice appears to be very various. In the part of the Angami country visited by me in my tour, the cultivation is, as far as I saw, mostly permanent, the terraced fields being built up laboriously with retaining walls and irrigated by channels led from streams. Among the Rengmas there is a little permanent cultivation, and in the clearances there is for the most part an attempt at terracing, and the land is cultivated, for two or three years successively. I was told that the practice among the Western Angamis and the Kutcha Nagas is the same. But among the Lhotas the system of cultivation is that of the *jhúm* pure and simple: the grass and reeds, the small trees and small branches of large trees, are cut and laid about the ground and burnt; the ashes are carefully raked and distributed over the ground, which is then hoed up, and the seed sown broadcast or dibbled in. Only rice is grown, and no irrigation is practised; but the *jhúms* are carefully fenced and assiduously watched till the crop is ripe. The same land is never cultivated a second year, but is left to lie

for seven or eight years till its turn comes again; and by a rough rotation of this sort almost all the land suitable for *jhūming* is taken up in turn. There is not much valuable forest left now, and what is left stands for the most part on steep and rocky ground. The question to be decided is whether any effort should be made to place restrictions on this wasteful mode of cultivation, and, if so, what restrictions.

Restriction of *jhuming*.

20. The evils laid to the door of *jhūming* are chiefly two; first, that it destroys the forest; secondly, that the soil, being exposed to the action of the rain, is washed away, and only the bare and rocky hillside is left. The first charge is undoubtedly true; but in a hill country so far from the plains, with little valuable timber and no demand for it likely to arise, beyond a very limited demand for houses at Wokha and for bridges on the road, there is not much cause for adopting any measures of protection beyond the obvious one that the tract should be inspected by a competent Forest Officer, and that any parts growing valuable forest trees should be set aside as Government reserved forests. With regard to the second point Mr. Hinde states that as far as his experience goes, the low jungle grows up so fast that the denudation of the soil does not extend beyond the first season, and that in its long period of fallow the repeated decay of vegetable matter restores the soil to its original condition, so that a hillside *jhūmed* for the second or third time produces as good a crop as when *jhumed* for the first time. This may be the case, but obviously there has not yet been time to decide this point by actual observation. Even if it were proved to be true, the increase of population which will follow on the protection and security afforded by our Government will in time necessitate a more careful and productive system of husbandry, and it would therefore be very desirable if these tribes could be gradually led to see the advantages of terraced and irrigated fields and of permanent cultivation. The labour entailed by *jhūming*, *i.e.*, the cutting of trees, reeds, and grass, and the fencing in of a new spot every year, is really greater than the labour of terracing would be in most cases. It cannot be supposed that any change can be effected except in the most gradual and tentative way; but the steps which I suggest are the following: First, the Assistant Commissioner at Wokha should investigate what the actual facts as to the rotation of lands are. Do the people really adhere to any fixed system, and can they point out beforehand what hillside will be *jhumed* next year and the year after, and each year in succession? Are any private rights supposed to exist in these lands, or can any member of the village community *jhūm* any portion he likes of the hillsides set apart for the year's *jhuming*? Secondly, they should be instructed that, though they may *jhum* lands which have been *jhumed* before, they must not cut down forest hitherto untouched or *jhūm* in new places without special sanction, to be given after the Assistant Commissioner has visited and inspected the spot. Thirdly, it would be useful if the Assistant at Wokha were to take up some suitable low-placed lands, and set the example of terracing and irrigating them, in order that he may learn by experiment what difficulties there are to be met and overcome. Further, in the course of time, when our influence has been more solidly established than it is now, it might be practicable to lay down a condition that no cultivator is to begin a *jhum* until he has at least terraced and levelled one field for permanent cultivation; but it would not be wise to do this till the people have acquired more confidence in our intentions, and more understanding of our methods, than they now possess.

Growth of potatoes.

21. In connection with this subject, I may mention that it is very desirable to encourage the growth of potatoes and other vegetables which are likely to sell well or to be locally consumed in the hill villages, and the Political Officer is requested to further this by all the means in his power, to procure seed at the proper season and distribute it to suitable persons with the necessary instructions, and to keep a record of the results.

SELECTIONS.

CULTIVATION OF RUBBERS IN INDIA.

THE first attempts which were started in July 1873 in the Darjeeling, Terai, and in the Goalpara district of Assam, were failures, but in July 1874 Mr. Gustav Mann took charge of the experiment with very satisfactory results. Three plantations have been formed. One, on the right bank of the river Kulsi, in the Kamrup district of Assam, consisted of 95 acres in 1879, on which were 2,895 plants. Another is at Charduar, at the foot of the Himalayas, 18 miles north of Tezpur, in the Darrang district of Assam, where there were 685 acres under cultivation in 1879, the growth of the trees being excellent and most vigorous. The third plantation is at Bamun, also near Tezpur. Here there were 8 acres planted with 459 trees in 1878, but the climate is too dry. No artificial shade is now given, and the young trees are healthy and vigorous. Experiments are in course of trial, to plant the *Ficus elastica* in strongly made baskets placed in the forks of trees, and on grass lands, as well as in the regularly prepared beds. The trees may be tapped at the age of 25 years. After 50 years they will yield 40lbs. of caoutchouc every third year, worth £34. In Cachar the india-rubber tree was discovered in 1862, and 750 cwts. were collected, the yield being increased to 1,500 cwts. in 1863. The yield from the first tapping is 35 to 40 lbs. The tree is then untouched for three or four years, and the second tapping yields much less. Mr. Edgar reports that Cachar forests would yield 2,000 cwts annually. In 1879 the quantity of caoutchouc exported from India was 10,033 cwts valued at about £61,685.* Besides extending the cultivation of the taxes, the officers in charge of the plantations will carefully investigate all such questions as the most favourable time of the year for tapping, and the best methods for cultivating and preparing the caoutchouc. The experimental cultivation of the *Ficus elastica* has thus been satisfactorily commenced in India, under the able superintendence of Mr. Gustav Mann.

1874—16,837	cwts valued at	... ...	£117,775

* Caoutchouc exported from British India during the last six years.

THE CINNAMON TRADE.

A WRITER to the *Ceylon Times* of the 5th instant, has warned the cinnamon growers against the practice of making chips and inferior cinnamon out of tops, and has recommended only the making of oil out of such stuff. The reason is plain enough, for when stuff is exported, a very large number of buyers manage to supply their wants by purchasing the same at a cost of cents. 20 or 25, instead of purchasing the dearer article at a higher rate. The result is a depression in the market of prices for good cinnamon. One who is accustomed to this trade has informed us that if the practice of making and selling chips is discontinued, the rate of one rupee per lb, can be freely obtained here for good cinnamon. For the sake of a profit of 8 or 10 cents per lb. cinnamon growers make and sell the chips, the loss resulting therefrom being that the people of London, as well as those of other continental towns, get accustomed to these chips and supply their wants that way and thereby keep on these low prices for good cinnamon. We see now plainly that the cinnamon grower exchanges a very small profit for larger and legitimate ones. Our advice therefore is, burn and reduce to manure all these chips, wood, black coffee, and all the refuse called bones, and to which we shall add bad areca-nuts, and our trade will then prosper.—*Lakrivikirana*, April 9.

THE BEHEEA SUGAR-CANE MILL.

AT the Lucknow agricultural meeting, virtually, the only sugar mills exhibited were the well-known ones patented and made by Messrs. Thompson and Mylne of Beheea in Shahabad. A specimen of Messrs. Cantwell & Co.'s (of Calcutta) patent conical-roller mill was indeed on the ground, but no one appeared to look after it, and it was not tried. But a complete set of the Beheea mills was on the ground, and the agents of the patentees were there to show how they were worked and give any information that might be required; and printed particulars both in English and the vernacular were distributed. This mill must now be too well known to require description. It is a portable machine for use in the fields, and in its simplest form is a pair of cast iron grooved rollers, with pinions working into each other, one of them being turned by leaver, to which one or more bullocks are yoked. These rollers are set vertically in a rough wooden trestle frame, the legs of which are embedded in the ground, and there are simple adjustments which ensure parallelism of the rollers, and that they shall be the proper distance apart. At Lucknow it was seen that the patentees had been making every effort they could to improve the mill and to meet the wishes and even whims of the cultivators. The novelties were, as described by our special correspondent—(1), a smaller mill, to meet the wants of the poorer cultivators, with rollers only 4½ inches in length, to crush three canes at a time, costing only Rs. 45, against Rs. 85, the price of the 6" roller-mill hitherto used; and (2), the introduction of three-roller mills, for all sizes rollers, for the better crushing of the thick canes cultivated in some parts of India. In the three-roller mills the juice is expressed more gradually, and the strain and consequent risk of breakage on the spindles is reduced. This year, moreover, the spindles have been made stronger, and the pinions deeper, and other improvements have been introduced. The price of a two 8" roller mill, thus improved, remains at Rs. 95, and that of the three 8" roller mill at Rs. 115; that of the three 4½" roller mill being Rs. 55.

As it has been found that the Punjabi sugar cultivator has a fancy for making ropes, sheaf-binders, and coarse mats out of the cane stalks, after the juice has been imperfectly expressed by his wooden horizontal smooth-roller mill, and he cannot do so with the perfectly desiccated and crushed refuse of the grooved-roller Beheea mill, the patentees are having multiple seven-roller mills made, which will pass the stalks out whole. It has been proved by calculation that it is cheaper to squeeze out every drop of juice, though, in so doing to break up the cane, and to buy other fibre for rope-making; but the Punjabi will have his own way, so he is to be humoured. Then, again, having found that, down-country, the native prefers the native *kolhu* because he can sit on it and go to sleep; Mr. Mann, the agent for the N.-W. Provinces, has contrived a sort, incapsizable bicycle for the driver to ride on. It consists of a light wooden frame, in which a pair of ekka

wheels is set, with the axles radical to the mill and close together, but one slightly in advance, so that its nave just clears the nave of the other, and on this is fixed a box for the driver.

The rate at which the use of these sugar mills is spreading is wonderful. In 1872 only 59 mills had been sold; but by 1876 the number was 1,825, all sold at Beheea, and chiefly for use in Shahabad. In 1877, the sale was begun in other parts of India, and by the end of 1879, 5,827 had been sold at Beheea, and 2,300 elsewhere, or a total of 8,127, and the estimate of the demand for new mills in 1880 was 4,000. At a fair at Saharanpore in February last, the demand for the mills could not be supplied. Two brothers, Syads Niaz Ali and Gholam Ali, of Jagadhri, bought 80 mills, paying for them on the spot, and wanted 100; and they ordered 500 for next year, to be paid for in advance. These enterprising men let the mills out on hire. Mr. Mann, towards the end of the fair, was quite mobbed by purchasers, holding out their money over each other's heads, and complaining that they had been waiting for days for their mills, and had not got them. Clearly, the prejudices of the natives of India in favor of their ancient ways are not irremovable. Towards this end, in the N.-W. Provinces and Oudh, the Department of Agriculture and Commerce has played its part, for in 1878 it obtained the sanction of Government to make advances to cultivators for the purchase of the mills, to be repaid with interest at six per cent., and it has frequently taken the trouble to exhibit them at district shows, and otherwise to make their merits known. In a recent circular the Director said: "If we may apply the results of this experiment to the total production of sugar in these provinces, it follows that by the substitution of the Beheea mill for the *kolhus* now used, the total annual produce would be increased by the value of nearly a crore and a quarter of rupees."

From the statememt circulated in the showyard at Lucknow, the following comparison of the working of the Beheea mill and the other two contrivances in use in Behar and the adjoining districts of the N.-W. Provinces, is taken.

1.—The Beheea mill, worked by three men and four bullocks, squeezed, in the season, 10½ acres of cane, and produced 400 maunds of *gur*, worth Rs. 3-14-6 per maund, or a total value of Rs. 1,561-8-0, at a cost of Rs. 29 per 100 maunds.

2.—The stone mill (*tikura*) worked by six men and eight bullocks, squeezes 7½ acres of cane, and produces 300 maunds, of *gur*, worth Rs. 2-12-6 per maund, or a total vlaue of Rs. 834-6-0, at a cost of Rs. 87 per 100 maunds; and

3.—The wooden mill (*kolhu* or *raksab*), worked by four men and four bullocks, squeezes 3¾ acres of cane, and produces 150 maunds of *gur*, worth Rs. 3-6-6 per maund, or a total value of Rs. 511, at a cost of Rs. 100 per 100 maunds. The comparision is put in another way, thus:—To squeeze eighteen beeghas of cane (11½ acres), in a season of four months, there are required—

1	Beheea mill,	4	Bullocks, and	3	men.
2½	stone	20	„	15	„
3	wooden	12	„	12	„

In connection with these mills there was also shown and worked, at Lucknow, a specimen of the evaporating pan used at Shahabad, which Messrs. Thompson and Mylne find is a much better vessel for making *gur* in than the deeper ones used in the N.-W. Provinces. It is five feet in diameter, but only three inches in depth, and produces 80lbs. of *gur* in an hour, of a quality very much better than that turned out by the deep pans, the risk of burning being greatly obviated.—*Civil and Military Gazette.*

SUMAC.

Sumac, which in one or the other of its varieties grows throughout the United States, has generally been regarded as a noxious shrub, which most farmers made war upon and destroyed, and nine-tenths of them probably would be glad to get rid of. Yet its production is really a profitable business when grown by culture. During the past ten or twelve years, our wild sumac has become more and more utilized, until in some sections it has attracted a degree of attention not known to the general reader. We have known for years that a considerable amount of the leaves had been gathered in Virginia, principally in the neighbourhood of Richmond, but were somewhat surprised, a few days since, to learn from Mr. C. D. Chambers, a citizen of Pamplin City, Albemarle county, that wild sumac had become an important article of traffic in his section of the State. None is cultivated there, however. Instead, the leaves are gathered from the wild shrubs, abandantly found there on the hill sides and poorer waste lands, mostly by negro women and children, and carried to the neighboring towns, where it is bought by the merchants, as they buy nuts, furs, wool, etc., in their season. At these points, the dried leaves are sacked and forwarded to Lynchburg, Richmond and Petersburg, where the sumac is ground in mills adapted to the purpose and used for tanning purposes, or shipped, mostly to eastern cities. Between the three cities named considerable rivalry exists, each of which has its "runners" sent out to buy up the stock, and sometimes become quite as much a bore as the famous "Chicago drummers." We have no means of determining accurately the amount of sumac gathering in Virginia, but it annually amounts to thousands of tons.

Until about 1866, most of the sumac consumed in the United States was imported, nearly the entire of the importation coming from Sicily. In 1866, the amount imported reached 136,872,572 pounds, valued at $155,191; in 1867, 18,790,990 pounds, valued at $559,421; in 1869 11,242,451 pounds valued at $468,362. These are the custom house valuations, which are the valuations at the ports from which shipped, yet give over 30 cents per pound, or over $60 per ton for the sumac. The American sumac, as yet, falls considerably below the Sicilian product in market value, in part in consequence of the fact that it is not cultivated with us, and hence is not uniform in quality, and partly because it has not been as well prepared by the manufacturers. This latter defect, however, has been in a large part removed by the invention of machinery employed now in its manufacture. Chemical analysis shows that the American sumac has 30 per cent of tannin, its valuable property, while the Sicilian has but about 28½ per cent. Notwithstanding the superiority of the American, it has never sold in our markets at so high a price as the Sicilian, bringing only a maximum of $90 per ton in 1869, while the latter sold at $180. In 1869 (the latest returns before us), 11,200 tons of imported sumac and 5,000 tons of domestic were consumed in the United States. Of the latter, Virginia produced 3,500 tons. But the home production is much larger now.

In the Agricultural Department report of 1872, we find that in that year 12,000 pounds of sumac were shipped from St. Louis to New York, and thence to St. John's, New Brunswick, to be used for tanning purposes, but whether produced in Mussorie or not is not stated. But that sumac can be grown in the latitude of this state, as well as in the latitude of Richmond, Virginia, we see no reason to doubt. The complaint, so far as we know, is, that it grows here too luxuriantly and is too difficult of eradication in the estimation of many of our farmers. In any event, it is quite certain that the leaves of our wild sumac may be gathered and made an article of commerce quite as readily and quite as profitable as in Virginia. The leaves (and these only are used with us) may be gathered at any time after they begin to ripen, about July 10, up to the appearance of frost. The leaves, including the stem (not stalk or branches), are placed in open sheds to dry, care being taken that they shall be kept from getting wet or becoming heated, either, of which impair or destroys their market value. When thoroughly dried, they may be broken up promiscuously, sacked, and marketed.

In Sicily, sumac is planted in rows about three feet apart, cuttings being used, and cultivated much as our corn is where level culture is practised. In this way two crops are produced, the first year after planting the first crop being cut off close to the ground, the suckers springing up from the stubs, furnished a second crop.—*Journal of Agriculture.*

DEEP PLOUGHING IN INDIA.

It has been said with much truth that if great Britain has any two duties towards India it is to teach her why not to lie and how to plough. We have not perhaps so much to preach the Ten Commandments here as to cure what Emerson calls the "pioneer state of things in the country," and to assist with the true British maxim of "Travers" in what Sir John Kaye terms "the oft-hoped, ever-realisable, but never perhaps to be realised hope" of developing the resources of the country. We have just now some twenty and odd gold and silver-lead mining companies throughout the length and breadth of the land; while the ryot, who, with his forefathers of happy memory, has been scraping the surface of mother-earth with his babul-bough, for the last 30 centuries, has not been taught either the meaning of the Catonian maxim *bene arare*, or the wholesome rule the late Mr. Mechi gave to the world, *viz.*, "a plough should be both a digger and an undertaker." That the subsoil of India contains within its yet unexplored recesses vast stores of plant-food and that the surface-soil has by a system of perfunctory agriculture been so far impoverished and debilitated as to grow only the lower order of crops, and these of a quality inferior to those grown in other parts of the world, is a truth which is no less fully established than it is alarming. The ryot has not yet realised this fact, but it is idle to think that merely preaching it even from the house-top to him will induce him to avail himself of his subsoil and thrust his plough deeper. He is steeped in ignorance and poverty. Ignorance can be eluttriated from his mind by precept and practise; by the experimental farms which Government have established in different parts of India. These farms, however, are too few and far between, and they do little towards instructing an agricultural population of some 180,000,000 inhabitants. We are glad, therefore, to note that the influential, though, as we remarked the other day, ill-advised deputation that waited on Lord Hartington on the 5th of April, warmly advocated the desirability of diffusing a more wide-spread and elementary education among the great mass of the people of India in strict accordance with the spirit of the Educational Code of 1854. Poverty, however, is not easily or so cheaply cured. It is the greater of the two cancers that eat at the heart of Indian agriculture; for, though knowledge be power, the knowledge of the use of a plough to the man who cannot afford to buy or even rent one, is so much throwing away of pearls on swine. Towards the permanently-settled zemindars of Bengal, Government have not half the imperative duty they have to the ryots of the Deccan, where the land is for the greater part in their own hands. Bearing in mind this consideration, as also remembering that by far the best part of the Indian revenue proceeds from the land, Lord Mayo, eleven years ago, called the urgent attention of the Secretary of State for India, to the duty of helping the

Deccan ryot. To this day nothing has been done. Mr. Wedderburn last year published a paper proposing a system of Permanent Settlement. The scheme was assailed with a full cry by writers, who should have known how to raise better objections than mere technical ones, and then the scheme was allowed to slide. We trust it is still under the consideration of the Secretary of State, and that it will be applied in due time to the Deccan, when the failure of the Agicultural Banks crotchet, as we anticipate, comes about.

Once cured of his ignorance and chronic bankruptcy and poverty, it will be an easy matter for the Deccan ryot to plough—and to plough well. The great saying of the epigram matic Cato: "*Quid est agrum bene colere? Bene arare. Quid secundum? Terum arare. Tertio? stercorare*" has been erroneously, or, at best negligently construed by writers on agriculture—and in these days of high scientific farming we ought to know more than even the Romans. The fact is that the subsoil though, as a general rule, richer than the surface-soil, should not always be brought into immediate play. Even admitting that the ryot is strong enough to use a powerful implement, it very often happens that the subsoil is poorer in, say, iron and alumina, the inversion of which would not only impoverish the upper soil but lessen its capacity to resist drought and insects. Sometimes again the lower soil is so raw, sour, and soapy that to conjure it to the surface would be the sinfullest act a farmer could commit. A scientific distinction has therefore been made between deep-*ploughing* and deep *cultivation*. We are not aware what ploughs are used by the Agricultural School in Poona—probably one of Howard's; but Mr. Chick of Calcutta lately took out a patent of whose wonders we have heard much. The plough, while strong and durable and capable of deep-ploughing, is said to be so portable that the weakest plough-boy can carry it to and from the field. It can be driven by one man and may be drawn by a pair of small bullocks, such as are commonly used by the ryots, the rearing of stock in India being notoriously a disgrace to the country. It is so constructed that while it ploughs deeper than the native plough, and with good bullocks will go to a depth of seven inches, it actually requires less exertion on the part of the ploughman himself than the native plough. He has to exert no downward pressure, but simply to guide the plough with one hand, while he drives the bullocks with the other. Such casual repairs as may be necessary may be executed by any village workman, and the plough, is so simple that the ryot can work it at once without previous instruction. The price is only Rs. 11-8, and though a little dearer than the native plough, is surely within the reach of very many ryots who, we are assured, would secure from its use a large profit from increased production. From experiments it would appear that, *coteris paribus* that Mr. Chick's plough is capable of realising for the ryot 30 per cent of production over and above his present maximum.

Besides Mr. Chick's experiments, others quite as successful have been lately made at Hissar, near Delhi, under the superintendence of General Angelo, which goes far to prove that the English plough can be thoroughly adopted to Indian requirements.—*Deccan Herald.*

OUR WHEAT TRADE.

THE subject of the enhancement of freight on the G. I. P. Railway is of interest to a great many people outside the Bombay Presidency. In spite of repeated protests by the mercantile community, the Directors of the G. I. P. Railway have issued an order which took effect on the 2nd instant, for such an increase in the ordinary rates as must, in the estimation of the trading community, have the result of lowering traffic. It seems that the Directors have been induced to take this step, in consequence of their diminished receipts after the end of the late famine. But it is equally evident that the traffic was gradually expanding during the interval. In fact, the volume of trade had so largely increased a long while back as to leave no room for doubt that the railway would soon be enabled to earn a good revenue and make up for past losses, without any such dangerous resource as the increase of freight charge. A few weeks ago, according to a Bombay contemporary, wheat trade from inner India to Bombay rose to five times its highest figure at any previous period, that is for the same month, and to ten times the average of the preceding five years. The same progress was manifest in the important item of linseed. But it is added that the wheat shipments for March were much below those for April, so that the conclusion is that Bombay may most probably witness an unprecedentedly successful season in the wheat trade. Yet as we have shown, this is the very time that the Railway Directors take in into their heads to impose fresh charges which must act in restriction of commerce. We have pointed out on former occasions, that notwithstanding the competition of the United States, India was quite capable of maintaining a large and profitable trade in certain kinds of wheat, as for example the fine kinds which are used in the manufacture of macaroni, and which are not grown in America. The figures quoted by our Bombay contemporary fully bear out all that we then said on the subject. It is worth noticing that the railway charges over the six hundred miles from Jubbulpore to Bombay even exceed the charges over the four thousand miles from the corn markets of Chicago to the port of Liverpool. While we are on the subject we may remark that wheat of excellent quality is selling at Sumbulpore, in the east of the Central Provinces, for more than sixty seers for the rupee, or less than a third of its price at Lahore. This means that immense quantities of wheat are grown in the Central Provinces, for which the cultivators have no use. As a fact, wheat is often used as fuel in that granary of India.—C. & M. Gazette.

EXPERIMENTS IN BREEDING AND REARING ADEN CATTLE.

MR. W. R. ROBERTSON, Superintendent of Government Farms, has submitted the following interesting report, which the Board of Revenue consider very satisfactory, and have sanctioned the expenditure of Rs. 1,200 as proposed for further importation:—

I have the honor to submit the following report on the experiment began at the Saidapet Farm in 1874 in breeding and rearing cattle of the Aden breed. The experiment has now reached a stage at which we may profitable summarise the results and form some general conclusions thereon.

2. In the Annual Report of the Farm for the year ending 31st of March 1874, I referred to the then proposed experiments as follows:—

"56. With the view of effecting some improvement in the cattle of the district around Madras, it is intended to import a few animals of the Aden breed. One bull, two cows, and two calves have been purchased for shipment from Aden to Madras by the first favourable opportunity. The Adens have a high reputation as daily animals; the name Aden by which they are distinguished has probably originated from Aden being the port from which cattle of this breed are generally shipped, they are not found in the neighbourhood of Aden, but are brought from districts situated at considerable distances from the coast. They are small animals, and the bulls of the breed are therefore better suited for use in the early stages of experiments in improving the breeds of small cattle generally found in Southern India, than are bulls of the Nellore and Mysore breeds, which in some instances have been used for this purpose. To show how great a mistake it is to use bulls of these large breeds in attempting to improve the cattle of Southern India, it is only necessary to mention that a cow of an average size generally weighs from 200 to 300lbs. live weight, while a good bull of the Nellore or Mysore breed will weigh from 900 to 1,000lbs."

3 In the next Annual Report the experiment is thus referred to:—

"63. In June we imported the Aden cattle referred to in my last report. One of the cows died during the voyage; the remaining animals, consisting of one bull, one cow, and two calves reached Madras in safety, but were all much out of condition when landed. The cost of the stock in Aden was Rs. 208-14-0, and for their conveyance, &c., to Madras, the charge was Rs. 630-12-0, making the total outlay on account of this importation Rs. 839-10-0. These animals are not nearly so good as I had expected that they would be, and if they are fair specimens of the breed, which I have every reason to believe, they are the Aden breed which has been much over-praised. I make this observation with reference to their form and their general quality only. I have not yet had an opportunity of forming a conclusive opinion regarding the milk-producing capabilities of the cow, though from the fact that she has reared her own calf along with the calf of the cow that died, she cannot be very inferior in this respect. Both the calves are bulls; one, the calf of the cow that died, is much inferior in form and quantity to the other. If the cow should prove to be a good milker, her defects in shape may be overlooked, for it must be remembered that there are several highly valued breeds of dairy stock in Europe, the cows of which are exceedingly irregular in form. If by the use of bulls of the Aden breed amongst the dairy stock of the ryot we can succeed in producing a cross, the cows of which will possess larger milk-yielding capabilities, the experiment will have been fairly successful and the improvement in form may be attempted by the use of bulls of some other breed."

4. The cow in October 1875, gave birth to a bull calf which she reared. No statistics are available showing the quantity of milk obtained during this milking period.

5. In May 1877 she again gave birth to a bull calf, and from that period her yield of milk has been carefully recorded. From the fourth day after calving, until the following March, she yielded 820 Madras measures, or 307 gallons of milk; the average monthly yield throughout, the period was 75 Madras measures.

6. In June 1878 the cow gave birth to a heifer calf. She continued to give milk up to following May. The total yield of milk in this milking period was 694 Madras measures, or 260 gallons, and the average monthly yield was 69 measures.

7. In September of the following year she again gave birth to a heifer calf. The yield of milk in this milking period was 831 Madras measures, or 312 gallons, and the average monthly yield was 83 measures.

8. On the 19th of July 1880, the cow gave birth to her sixth calf. Unfortunately about the end of December she was attacked by foot-and-mouth disease, which for a time put a stop to the experiment, but in the five months she was milked, she yielded 564 Madras measuses, an average yield of 3·8 Madras measures or 11½ pints per day.

9. The quantities of milk mentioned were obtained in addition to that consumed by a calf reared in each of the milking periods.

10. The milk was excellent in quality, 16 to 17 pints, yielding one pound of butter.

11. From May 1877, from which period accurate statistics are available up to nearly the end of December last, the total yield of milk was 2,910 measures, or 1,091 gallons, and during this period the cow reared four calves.

12. There has been but little change in the food of the cow, usually she was fed as below:—

Daily 4 lbs. of ground-nut oil cake.
,, 2 ,, of wheat bran.
,, 80 ,, of green fodder.
,, ½ oz. salt.

the average prices of which may be taken as—

Bran, at 50lbs. per rupee.
Ground-nut oil cake at 75lbs. per rupee.
Green fodder, at 300lbs. per rupee.
Salt, at 81lbs. per rupee.

or Rs. 6-12-0 per mensem, to which must be added Re. 1-8 per mensem for attendance and sundries, thus making the total monthly expenditure Rs. 8-4-0. For the entire period, forty-three months, the cost will have amounted to Rs. 354-12-0. Deducting from this sum Rs. 100, the value of the four calves reared, there remains Rs. 254-12-0, which represents the cost of the 2,910 measures of milk obtained, the price per measure of which would thus be As. 1-5 or about half the price which is readily paid in Madras for much inferior milk. I have made no charge for bedding straw because the manure of the cow would be a fair equivalent for it. In charging for attendance, I assume that one man on a wage of Rs. 6 per mensem could easily manage six cows.

13. We have now at the farm of the Aden breed five bulls, one cow, and three heifers. The bulls are in considerable request for use with the small cow of the neighbourhood. They are regularly employed in farm work, carting, ploughing, &c., and are remarkably docile and steady at work.

14. The result of the experiment has been so encouraging that I venture to ask sanction for the expenditure of a sum not exceeding Rs. 1,200 in importing a fresh supply of the cattle from Aden, say two bulls and four cows with calves. The expenditure can be met from sanctioned allotment. "Farm Stock" in the budget for the current year. I assume that the stock could be brought across for Rs. 100 per head as shipping facilities with Aden have been so greatly increased since our last importation. If this request is sanctioned, I shall be glad if arrangements can be made through the Political Resident at Aden for the purchase and shipment of the stock. I shall be glad to furnish a detailed description of the kind of animals we require.

15. Of the Aden stock we now possess, I purpose placing a bull at each of the three Agricultural experimental stations it is intended to establish in connection with High Schools.

16. I enclose a statement showing the monthly yield of milk from the Aden cow during the last four milking periods, and another statement showing the monthly yield of milk from three cows of the Punganur breed, a breed which possesses a considerable local reputation as dairy a breed. The last statement shows an average monthly yield of milk during the milking periods from these cows of only 30 measures, in addition to the milk taken by the calf each cow reared, or only about ⅓th the monthly yield of the Aden cow.

THE TENURE AND CULTIVATION OF LAND IN INDIA.

SIR GEORGE CAMPBELL, M.P., recently read a very interesting paper before the Society of Arts on this subject, which we reproduce at length. Sir George, in that portion of his paper, takes a strange view of the labour question so far as planters are concerned. Apart from this remarkable expression of opinion, which we imagine planters will thoroughly dissent from, there is much that is instructive in the paper.

My subject being "The Tenure and Cultivation of Land in India," I shall first speak of the tenure of the land. The most prominent feature throughout India is this, that everywhere the soil is held by small farmers not above the position of labourers. Speaking generally, it may be said that there are no large farmers. We found that in India under the native system the rent was in the main retained for the purposes of Government. The Government dealt with villages; those villages were little Republics—the units of the States; they managed their own affairs, distributed the revenue demand, and provided for many common expenses and common necessities by a well-arranged system of local rating. Under our system, the revenue demand has been moderated, but much variety of tenure has been introduced intermediate between the Government and the people, giving rise to very various forms of property. It seems to me that in this process we have done harm, from acting upon English ideas, in two directions. In some parts of India we have attempted to establish landlords, in the hope that they will perform the functions of English and Scotch landlords; in reality they have entirely failed to do so, and the people are under this system more rack-rented than under the native Governments. The free-trade system of free contracts between landlord and tenant has answered no better in India than in Ireland; in some cases great political difficulties have resulted, as when through mere ignorance we have imposed Bengalee and other landlords over Sonthals, Gardos, and other aboriginal tribes, the autochthenes of the soil, and, in their view, its true owners. In other parts of the country, an opposite course has led to another class of difficulties; there, rejecting the landlord system, we have made the ryots the cultivators of the soil, absolute owners of the soil, and insisting upon the advantage of individual property, we have put an end to the system under which, in a village community, the combined cultivators had the strength attributed to a bundle of sticks. This course was certainly taken with the best intentions in the world, but it has turned out that in some cases an unaccustomed form of property, given without price and without safeguards and limitations, to people who did not understand it, has been treated by them as children treat a gift beyond their years; they have made too much use of their new-found credit, they have become involved with money-lenders and signed away their rights. They have been sold up by the courts under our rigid system of law, and sometimes, as in the case of the Deccan ryots, their last state has become worse than their first.

The moral, however, of the difficulties which have been experienced, both under the landlord system and under the ryotwar system, seems to me to be that it was a mistake too suddenly to introduce our ideas of property, and that a limited sort of property of the nature of a liberal fixity of tenure is more suited, at any rate in the first two or three generations to our rule in India.

I have now come to the cultivation of the soil, which I am afraid we hardly so well understand as we do the tenure. The great question which has been raised of late years is whether the soil is becoming exhausted at the same time that the population is rapidly increasing, so that grave and dreadful evils may be feared. The population, no doubt, is increasing, but we are still without sufficient data to show the rate of increase; nor has it been made clear whether famines are really more frequent than formerly, or whether we have only had recent unhappy cycle of famines which may have occurred in former ages, of which we have little information. My impression is, that the exhaustion of the soil is rather a thing which there is reasonable ground for apprehending, than a fact which has yet been made apparent beyond doubt as having actually occurred on a great scale. That a process has been going on, leading to much reasonable apprehension, is, I think, patent. We acquired India after terrible troubles, which had caused very much of the land to lie waste; there were many blanks; the last two or three generations have been filling up those blanks. They found much new land, which they brought into tillage; there is comparatively little left now; there is less room for grazing, less for fallows, more people to feed, and more produce exported. No doubt the soil must be exhausted in the end, if improved methods of cultivation are not introduced. Hitherto the great panacea for everything has been irrigation; but now there are very grave doubts whether increased irrigation, without increased manure, is not too much in the nature of a mere stimulant, and does not cause exhaustion and grave evils in the end. I think there can be no doubt of this, that limited portion, of the soil are very highly and skilfully cultivated by certain classes of natives in their own way.

I am glad to hear that a beginning has been made of sending one or two natives to the Agricultural College in Cirencester, and I hope that will be followed up. It is true that many of the free, unofficial Europeans cultivate, very successfully, tea and indigo, but they have enough to do to apply themselves to their own special articles, and have not generally given attention to the ordinary native cultivation.

As to the most profitable staple, I fear that some of our old staples do not progress. The export of sugar and silk has rather gone back; and from what I have seen of the cultivation of cotton in America and the great aptitude of the negroes there for this cultivation, I very much doubt whether India will ever compete very successfully with America in the cotton markets of the world. I rather think that the best hope for Indian cotton is in the development of the home manufacture of the article, by which cultivator, artisan, and consumer will be benefited. On the other hand, we well know that, on the whole, there is a continual increase of exportable produce. Wheat seemed likely to become a very great staple for export; and I still hope it will be so; but the difficulty to which I have already alluded especially applies to wheat. All the alluvial soils, which grow wheat well without artificial irrigation have already been occupied. A great extension of wheat cultivation is scarcely possible without irrigation; and some of the canal lands have certainly become very much exhausted for want of manure. The competition of cheap American wheat stands, too much in the way. But, on the other hand, India has almost a monopoly of the rice supply of the western world, and there is no limit to the demand for rice. In rice, we wholly beat the American: Indian rice is now largely imported into America; we cannot, then, grow too much rice. It seems too, that rice only needs an abundant supply of water, and that it does not exhaust the soil so much as other crops. I hope that some of the rice canals, such as that in Orissa, which have not hitherto been successful, may succeed in the end. They have had to struggle with very great difficulties, owing to the mismanagement of the private companies who at first undertook them, and which demanded exorbitant rates before the people were ripe for them. There are also very great difficulties in the distribution of water connected with the tenure of land. I hope that there is still room for a very considerable extension of the production of jute, oil-seeds, and similiar great articles of export in Assam and some districts of Eastern Bengal, in the Central Provinces, and in some other parts of India. Putting aside here all political and moral question, I think it may be said, as a mere agricultural question, that the opium cultivation continues to flourish, and the value of of opium exported becomes larger year by year. No substitute for indigo has yet been found in coal, or anything else, and I believe that the cultivation may yet go on and prosper if the indigo planters will only avoid the rock that threatens them; that is, that they cling to a feudal system of growing indigo by compulsion, when it would be much better for all parties to give a

fair price for it, and get it by free contract from free cultivators. The tea cultivation, notwithstanding its ups and downs, has been an immense success. I am afraid it is a little down at present, but I do hope that the tea planters will not be led into unfair demands upon Government for the remedy of their labour difficulty. Unhappily, there is still a very great mortality among the coolies employed in many of the tea gardens, which imperatively requires the attention of Government, in the cases of coolies who are not free labourers, but bound down for terms of years, enforced by very stringent laws. No one is more for freedom of contract beween employer and labourer than I am, but what I do object to is any demand for freedom for the planter while there is no freedom for the coolie. One would suppose, from the things that are said, that the Government throw all kinds of obstacles and unnecessary restrictions in the way of the planter, while the coolie are free to do as they like. The fact is just the contrary; if a planter engages a coolie under the ordinary civil law, the Goverment in no way restricts him; but what the Government do say is this, that if you insist, as you have insisted, that you should have penal laws of the most stringent character to enforce civil contracts of labour by criminal processes, and by powers put into the hands of the planters themselves, then the Government must exercise a certain supervision for the protection of the coolies, who are for the time not free labourers at all, and are liable to be sent to the most unhealthy places and kept there. I have no doubt, then, about the proposals for new legislation on the subject. My remedy for the labour difficulty would be to give very greatly increased facilities for the transfer of labour, and the free hiring of labourers without any penal or special laws at all. I should like to see as many new roads and railways as possible, to connect the provinces with over-abundant population with those whose population is scanty. In particular, I should very much like to see a cross railway connecting the Benares and Bahar provinces through the Northern Bengal with Eastern Bengal and Assam. But the question of migration and emigration of the natives is a very broad and difficult one, on which I cannot now enter. There is still, no doubt, room for a good deal of migration in India, but it can only be carried out gradually and carefully; and I am myself much convinced that both to the people of India and to the tropical possessions of her Majesty, very great advantages might result from an extensive Indian colonisation, if we could only make sure that Indian emigrants would be fairly treated under Colonial laws, and by Colonial administrators—an assurance which, in my opinion, we have not yet obtained. I think emigration should be encouraged when, and only when, an Indian going to a colony is there treated in the same way as any other of her Majesty's subjects, However, I will not enter upon the subject now. I am afraid I have already been too long, and I will only commend the subject of Indian land and Indian agriculture to you as being far more important to the people of India, and to all who are interested in India, than all other subjects put together. I hope that there may be fulfilled that which her Majesty's Government have put forward as their desire, namely, less of wars and more attention to agrarian affairs.

THE INDIAN GLOW FLY.

MR. H. A. SEVERN, F.R.A.S., writes from Devalah, Wynaad :—

"Having failed to find any critical description of these interesting insects—it is possible that the notes I am now able to send you may cause others to enter the field of inquiry. Situated some 2,900 feet above the sea, and in central Southern India, amidst hills, valleys, and streams, I have had peculiar opportunities for observing them. They are not to be seen during the day time, but so soon as darkness steals upon twilight, so surely do these small natural lanterns become visible, and their numbers rapidly increase, much indeed, as the visibility of the stars increases as the evening passes into midnight. The fire-fly, when examined individually is by no means a pretty looking insect, and when compared to other insects and flies, it is certainly both large and ungainly. An ordinary house fly is 5/16 of an inch in total length and weighs ·25 grains; but the subject of my notice, has a length of 9/16 of an inch, and weighs ·66 of a grain. The glow-fly, or beetle, as I should term it, has a black head and antennæ; the thorax and abdomen are of a yellow red colour; two pair of legs are attached to thorax; third pair to abdomen. This latter part of the insect's body is divided into six rings; and, counting from the thorax, it is the fourth ring which emits the light; there is a rectangular opening in this ring which is merely covered by a very thin skin, it is in fact a window, from whence the light emerges! The insect has only one pair of wings, these are small, most delicate and thin, and are sheathed. It is worthy of notice that these insects fly both rapidly and slowly, but make no noise or buzz in the air. To test this further, I have frequently liberated several of these glow beetles in my bed room, and in the dark they have only appeared as fairy stars, as no humming could be detected. As regards the character and quantity of the light, one insect enables me to see the time by a white-faced watch when 4 inches distant; twelve of them placed in a glass jar enable me to read a book with ease; and are equal to a small "Geissler's" tube. The light is of an exceedingly beautiful colour, a sombre yellow tinged with green, and at intervals it is brilliant. A preliminary examination of the light in the spectroscope (a large one made for me by Browning), shews a distinct clear continuous spectrum, no lines or bands of any kind being visible. The insect made to crawl on a card placed over the poles of a powerful compound permanent magnet, showed no signs of uneasiness, or change of light. Similarly placed over an electro-magnet (10 groves cells) and rapidly alternating the current, caused no change; placed within a coil of covered wire there was no change. Blowing my breath very gently on the insect caused no change; this was also tried with a blow pipe. Cold air of 50° caused a distinct diminution of the light; on the other hand, air at 100° caused an increase of light. I now placed several of the insects in a bell jar, and gave them a good supply of clean oxygen gas, the luminosity at once increased fully 25 per cent. on a dead insect (which still emits light). Oxygen gave similar results, and on extracting the luminous part, and blowing oxygen upon it, the light was much increased.

"So soon as darkness has fairly set in, millions of these beetles invade the trees, and as my bungalow is near to a stream and level with the top of the trees, I am able to notice them with much care. The curious pulsation or flashing of their light is remarkable. The insects resting on a tree, all act in perfect concert, i. e., five seconds of no light, then seven rapid flashes; five seconds no light, seven flashes; and so the game continues throughout the dark hours. At first I had reason to believe that the insect when flying only emitted light; this, however, is not the case, for when observing the pole star for variation with my theodolite, it occurred to me during a passing cloud to turn the telescope on to the glowing tree. At once I had the field of view filled with tiny stars both fixed and wandering. It is also worthy of notice that all such glow insects as may be on a dozen or more trees, will continue to keep up the most perfect time, as to the flashing of their light, and the interval of pause; and this, for many consecutive hours. But this singular agreement as to time, relates to close clusters of trees only; consequently, distinct groupes of trees separated one or more hundred yards may not agree, and do not do so as a rule. On safe authority I am informed that the Indian bottle bird protects his nest at night, by sticking several of these glow beetles around the entrance by means of clay. And only a few days back, an intimate friend of my own, was watching three rats on a roof rafter of his bungalow, when a glow-fly lodged very close to them, the rats immediately scampered off. In conclusion, I may say that these insects see by day, as well as by night, and I incline to the idea that the beautiful light they carry serves as a means of intimidation or protection, and certainly as a means, whereby to recognize friends. As I gaze from my verandah down the Nadgani Valley into the dark night, I see the pulsations of light, here, there, and everywhere; and as my optical powers increase, so do these gaseous nebulous patches become resolved into real living stars!"—*Madras Mail.*

FRENCH BUTTER.

FRENCH butter is sent to market in a great variety of packages, according to the requirements of each locality. For the London market kegs holding about 70 lbs. each, crocks holding 50lbs., and boxes containing one doz. 2lbs. rolls are most frequently seen. Extreme cleanliness and refreshing neatness (amounting almost to what the French call *coquetterie*) are characteristic of all the methods, and they are further distinguished by the free and almost lavish use of clean linen linings. The kegs and linen linings cost about 1*s* 9*d*. each; the crocks which are protected by an outside basket, and also lined with linen cost about 2*s*. each, including everything; and the boxes holding a doz. rolls cost about 9*d*. each, including linen and paper. In the hottest weather the boxes are sometimes double, the space between the two boxes being filled with cotton wadding. In fact, the French butter merchants thoroughly realize the importance of delivering their wares in an attractive condition, entailing neither trouble nor waste upon the retailer. On this point I may be allowed to quote the remark of an English friend:—' My cheesemonger said to me the other day. " Look here at this French box. I open it" (which he did); " here is the butter fit to weigh out to you without an atom of loss. Now let us break open this cask of Irish; you see I have to scrape it all round, and lose a lot, besides the trouble."'—*From 'Dairy Farming,' by Professor Sheldon, for April.*

OSTRICH FARMING.

IN July last, when travelling to Grahamstown, Graaf Reinet, and other places, I was much surprised, notwithstanding all I had previously heard regarding the prosecution of ostrich farming, at the extent to which the breeding of, and dealing in ostriches had attained, and the large returns which are in many instances derived by the hatching and rearing, the purchase and re-sale of birds, and the crops of feathers which are plucked from them (according to the fancy of the owners) every six or nine months, as also at the large sales of feathers held on the market at Port Elizabeth every week, on Mondays, and Tuesdays, throughout the year, these sales average from 8,000 to £15,000 weekly, the first amount being considered rather a low return. The total value of feathers sold on this market alone (irrespective of sales inland, or in the Western Province, where ostriches are also bred), during the six months ended June 30th, this year, amounted to £276,188 1s. 10*d*., and for the year 1879, the total sale were £391,120 11*s*. 8*d*., and I think I may safely put down at least two-thirds of this sum as the returns from domesticated birds, the proportion of wild feathers being very small.

I find that pairs of breeding birds are frequently kept in back yards, or paddocks, of from about a quarter of an acre up to two, four, and ten acres extent, while birds not yet paired off, run together in droves of 40 or 50 in large enclosures—that large numbers of chicks are hatched by the parent birds in these paddocks, and removed when three or four days old, to be reared by hand, the old birds, in most cases, frequently laying again in from eight to ten weeks thereafter, and ostrich nests may sometimes be seen within a dozen yards of the line of railway. It would take up too much of your time, now, to give the various statistics and statements made to me by owners of birds, who have been successful as breeders and feather-growers, but as illustrations, I will quote just two or three out of many instances. All are not, however, equally successful,

A gentleman who resides at Grahamstown, only some three years out from England, informed me that he had invested £1 000, partly in young and partly in breeding birds, which he placed with a neighbouring farmer on half shares of profits, the farmer finding food, land, and all that was necessary otherwise, that after twelve months investment he cleared as his half share £700 by feathers, birds resold, chicks bred and sold, &c., and he knew of several pairs of breeding birds which had realised their owners from £200 to £800 a year. Another party purchased for £120 a pair of breeding birds; 12 months afterwards £140 had been realised from feathers and young birds sold, and he considered he could get £350 for what he then had on hand; these of course were purchases made at lower value than are usually current just now, except in forced sales, pairs of guaranteed breeding birds, four or five years old, are worth from £150 to £200 per pair. One other case; two pairs of breeding birds were placed with a farmer on halves of profit, the one pair for six, and the other for twelve months, the half returns being £220 for chicks or young birds only with the old birds still on hand. Ostriches seem to do both in scrubby brush country and open veldt, and I am informed that their feathers are little if at all injured by moving amongst the bushes. £8 to £12 10s. per annum is considered a fair ordinary return in feathers per annum per bird; odd male birds sometimes return £15 to £18 per annum, these not being breeding birds however.

One gentleman, Mr. Distin, of Tafelberg Hall, Graaf Reinet district, has about 1,000 breeding birds and innumerable enclosures on his firm; he is supposed to realise at least £10,000 a year by ostriches.

The common prickley pear plant (*spun tia vulgaris*), which having spread itself over large tracts of country had previously been considered a pest, and large sums spent by some lando wners in attempts to eradicate it, is now found to be good green food for ostriches. Stuck on a fork or stick, and run through a blazing fire to scorch the thorns, it is chopped up with or without lucerne; mealies and barley are also used to feed with.

I was informed that the first census taken of domesticated ostriches in the Cape colony in 1865 was returned as 88 head, in 1875 the second census returned 22,000, the number now is believed to be quite 100,000, Companies are now being formed to prosecute ostrich farming. The objections raised by me against further extension of this enterprise, namely, that at the present rate of breeding and the production of feathers they would soon become a drug in the market, was combated by the following remarks. "How comes it, then, that up to the present, though the supply has yearly been increasing their value is still maintained, and that feathers being worn all over the world by ladies, children, and females of all classes, and being very destructible articles will always meet with sale." That being further proved by diamonds keeping up their value, though almost indestructible and found in large quantities yearly they also being articles of luxury, and unattainable by many persons owing to their value.

I put forward these arguments at length, now, because I feel persuaded, after seeing the kind of country these birds do well on in the sister colony, and the way they are treated there—that they may be successfully farmed here in many localities, such as the higher and open portions of Uys Doorns, where only lightly dotted over with brush and the Upper Tugela and Weenen districts, which are more or less of a dry climate and sandy character of soil.—*W. G. Baker, President of the Maritzburg (Natal Agricultural Society.*

FOOT AND MOUTH DISEASE.

As cattle disease in its various forms is prevalent in Oudh, the following letter on the foot and mouth disease addressed to the *Times* by Mr. W. Scott of 4, Austin-friars, London, may have some special interest for our provincial agriculturist and others. Writing under date March 26th, Mr. Scott says.—

"In arranging the papers of my brother the late Mr. T. C. Scott, I have come across to-day a cure for the foot and mouth disease which he called attention to in a short note in the *The Times* in 1869. And I find over 130 letters addressed to him requesting a copy of the recipe which he had printed for gratuitous distribution. Will these 130 gentlemen or some of them tell us through your columns whether they tried the remedy and personally saw it tried, and what the result was! The following was the recipe.—'Dissolve 1lb. of bluestone (sulphate of copper) in a gallon of soft water and wash the animal's mouth with this from a sponge attached to a stick; then put two or three large table spoonful of oatmeal and pounded alum mixed in equal proportions into their mouths as near the root of the tongue as possible, and the discharge of an immense amount of saliva will be the result. Wash their feet, especially between the claws with the same solution and allow them to stand on dry straw. Three applications daily will cure the worst case, especially now when the disease is so much milder than formerly. During the continuance of the complaint all food must be given chopped, as the cattle cannot lay hold of anything with their tongues. Sulphate of copper costs about 8d. per lb., and pounded alum less, and oatmeal can be obtained at any corn chandler's. The disease, as a rule, is not deadly. The worst effect of it is to throw back the condition of the affected animals for two or three months. My brother asserted that the above prescription would arrest its progress in three days. He considered it an infallible cure as tested by himself in 100 cases, in Cheshire when the disease first appeared there. One obvious advantage of the above prescription is, that it can be applied by any ordinary cowman or cattle man, thus obviating the employment of professional veterinaries, who must inevitably carry about this—as my brother deemed it—most infectious disease in going from place to place. Chloride of lime my brother considered a valuable preventive, testimony of its efficacy having been borne to him, at the time, by Mr. Parsons Fowler, the well-known importer of Alderney cattle. This disinfectant is to be sprinkled over the cowhouse floors, under trees where the cattle are in the habit of standing, at gateways, &c."

EXPERIMENTS WITH MANURES IN ABERDEENSHIRE.

Mr. Bruce, Millhill, Aberdeenshire, gives the following results of experiments conducted on his farm last three years. The experiments were conducted on a basis of 4 cwt of Peruvian guano per acre, all the other manures having been made up to that value.

The following were the results on the turnip crop of 1878 :—

Manures				Turnips per Acre. T.	C.
1. Bone ash yielded.	...	...	...	16	1
2. Bone meal, fine ground	...	...	...	19	7
3. Do. ordinary	...	...	...	18	8
4. Coprolites ...	...	...	...	13	7
5. Dissolved bones	...	...	...	18	18
6. Guano	...	...	...	22	10
7. Superphosphate ...	...	...	...	18	8
8. Guano and Coprolites	...	...	...	21	8

The results of the same manures were observed on the succeeding grain crop in 1879, and reported as follows :—

			Marketable Corn per Acre. Q.	B.	Lbs.	Light Grain. Lbs.	Straw. St.	Lbs.
Bone Ash	...	...	3	5	24	96	122	10
Bone Meal	...	...	5	2	36	192	171	14
Coprolites	...	...	3	7	8	96	120	0
Dissolved Bones ...		...	3	6	16	96	113	0
Guano ...	...	...	4	6	8	112	176	20
Superphosphate ...		...	5	2	36	118	171	14
Guano and Coprolites		...	3	0	0	64	93	0

The annexed are the results of the experiments of 1880 on the grass crop weighed as it was cut green :—

				Grass per acre. T.	C.	Lbs
Bone Ash	...	...	...	2	9	16
Bone Meal	...	...	...	3	6	16
Coprolites	...	...	...	2	1	18
Dissolved Bones	...	...	...	2	1	18
Guano ...	...	...	...	3	7	34
Superphosphate	...	...	...	2	10	32

In weighing the grass that was made into hay, the different manures gave nearly the same proportion of hay, except the bone meal, which was the heaviest, beating the guano.—*N. B. Agriculturist.*

CULTIVATION OF THE CHESTNUT IN TUSCANY.

The chestnut tree has existed for centuries in Tuscany, where at one time nearly every hill and mountain side was covered with its foliage.

The number of trees existing in Tuscany and Lucca at the present time is estimated at several millions, and the nut and wood have contributed more to the maintenance of the population of some of the districts than any other production; in some places, in fact, wheat, flour, and corn meal are entirely superseded by the chestnut flour, which is very nourishing and much cheaper as an article of food. The tree grows to the height of 60 or 70 feet, and attains full maturity at the age of 60 years, its vitality and productiveness last for more than 100 years. In many parts of Tuscany it is largely cultivated, and is always raised from the seed or nut; the larger variety of Spanish chestnut is cultivated from grafting on the young trees. Mr. Schuyler Crosby, the United States Consul at Florence, states that there are six different kinds of chestnuts cultivated—the Marone, the Carpinese or Carrara, the Pastinese, the Rossolo, the Romagnuolo, and the Brandigliano. The method of cultivation is as follows :—The chestnut is raised from the fruit, planted in earth which has been softened by being repeatedly worked over. The plantations are generally situated near a stream, and the ground shaded by hedges or trees placed close together. The space set aside for the cultivation of the chestnut is divided into furrows, six or seven feet wide, and in each of them holes are dug about three inches deep, and at a distance of about six inches from each other. In these holes the nuts are placed, with the germs downwards. The use of manure is not largely resorted to, although it has the effect of rendering the plants more vigorous and healthy, as it is dangerous on account of transplanting, as the young tree, finding itself on soil less rich than it has been accustomed to, easily languishes and dies. After two years the plants are transplanted to another part of the plantation, where they remain four years, after which they are placed where they are destined to remain permanently. The season usually chosen for transplanting is after the falling of the leaves, though it is frequently done even as late as February or March. There are two methods of grafting the tree (which is done at the age of five

or six years); one is the primitive method of inserting the bud in the end of a branch, with a slit in it, where it is retained by wax or other substances. The other, which is the latest, and has proved the most successful in its results, consists in cutting large rings of bark from the branches of the large or Spanish chestnut, and placing them on twigs of the ordinary kind; this is a very delicate operation, requiring great care, and is performed in the following manner:—The bark of the Spanish chestnut is cut into circles on the twigs, where marks of buds appear, care being taken to have one or more buds on each circle or cylinder, the bark is then slightly beaten to loosen it from its position, and gently twisted by hand, until a hollow cylinder of bark is obtained, which is then drawn up by the stem that has been previously denuded of its bark in like manner. The cylinder of bark is then carried to the stem of the tree, which is grafted. This stem having been previously denuded of its bark, and cut off down to the place where the ring is to be put on, is then covered with the ring, which unites with the growing bark, and sends out shoots of its own variety. In this manner a tree is covered with these rings, and the natural branches being cut down, all the force of the tree is expended in throwing out the shoots of the large chestnut from the grafted branches. Great care is always taken to cut off all shoots of the common chestnut that may appear near the grafted part, as they interfere with the full development of the part grafted. The operation of grafting by rings is practised in Tuscany from the 10th of April to the 1st of May, that being the time when the sap is running most freely, just before the leaves and buds come out. A method of preserving the grafting buds so that they may be good even after a year, is to place them in tin tubes filled with honey, and hermetically sealed immediately on their removal from the tree; another method of transporting the grafting buds, is by putting them into hermetically sealed tubes filled with water; this method can only be used for transporting the buds for distances accomplished under forty days. The chestnut produces flowers, which, after the usual process of the male pollen being deposited on the ovaries of the female flower, become chestnuts or the seeds of the tree; this change of the flower into the nut takes place about the end of July, and it is easy to foretell the crop of the year by the state of the nut germs, for although the flowers may have been abundant, fecundation may not have taken place largely, and it is only by watching the tree carefully after it has flowered, that a judgment can be formed as to whether the production will be good. The ovaries that are not fecundated by the flowers change into useless shells, but those which are fecundated become enclosed in buds containing one, two, or even three chestnuts. The nuts arrive at maturity in two months after flowering, that is to say, in October, and then fall to the ground; they are also beaten from the trees by peasants armed with long poles, but this is only occasionally done, as it seriously injures future fruit buds, and affects the yield of the tree for another year. The chestnut is pruned and trimmed every three years, which while helping the tree to bear more abundantly, produces wood for fuel and other purposes, and the smaller twigs and branches which are dried and used later for drying the nuts. The leaves are also gathered when green and young, and pressed flat in large bundles, and are then used for putting under pats of butter, and in making a kind of cake called "necci."

The Spanish chestnut has been cultivated with more than usual care and success in the province of Lucca owing to the laws to protect it from destruction, passed by the Lucchesan Republic in the eleventh century. The chestnut is a very healthy tree; in fact, the only disease to which it is liable is internal decay of the trunk. Cases have been known where the whole life of the tree has been carried on through the external bark while the interior was completely destroyed; the only way to arrest this disease is by burning out the whole of the interior of the tree by a slow fire. After the nuts are gathered, which is done by picking up those which have fallen and not by beating the tree, they are deposited in huts, in the upper part of which deep trays are constructed on which the nuts are placed to the depth of six inches; in these huts slow fires of green wood are kept up until they become hard and dry. They are then carried to the mill, where they are ground into flour, in the same manner as corn or wheat. From this flour many preparations are made such as "polenta," and various kinds of cakes, fritters, and even a heavy kind of bread. The different ways of cooking the chestnut flour are known under the popular names of "necci," "pattoni," "castagnacci," "cialdi," "fritelli," &c., and the food so made is sweet and agreeable to the taste. The country people cook the chestnuts in water and make use of this water as a medicine for chest diseases colds, and coughs, and in most cases it has proved beneficial. The food made of the chestnut which is most in favour, is the "polenta," made by simply boiling the chestnut flour in water for ten or fifteen minutes, with a little salt to flavour it, care being taken to keep up a constant movement of the paste, so that no part becomes burnt, which would thus spoil the mess; it is eaten with cream, butter, ham, &c., and is most healthy and nutritious. Another kind of food made from the chestnut is called "necci," which is flour formed into a cake, and is made by first mixing the flour with cold water, and making cakes piled on each other, and separated by chestnut leaves, pressed for the purpose, and moistened by water, the whole mass is then cooked over a hot fire, and the cakes taken off one by one, when the leaves are almost burnt. These cakes are generally eaten with cheese, Bologna sausage, and meat. Consul Crosby states that, in these regions where the inhabitants live almost entirely on the chestnut, they are of better appearance, and as strong as those who live on what is considered more wholesome and nutritious food.—*Society of Art Journal.*

EXPERIMENTS WITH MANURES.

THE following experiments with artificial manures were tried by Mr. James Johnston, yr. of Gear, Secretary of the Orkney Agricultural Society, with the view to find out the best proportion of potash to apply to the potato and turnip crops, and also as to whether animal or mineral phosphates in a soluble or insoluble state were best. Each experiment consisted of a drill five chains long.

1st. Potatoes.

The soil, which was a light loam, got a top-dressing of farmyard dung applied to it, and ploughed in the autumn The potatoes, which were rocks were planted in April. The artificial manures were sown in drills along with the potatoes, and cost at the rate of about £2 per acre.

	Rate per Acre.		Weight of Crop p Ac. T.	C.	Q.
No. 1.	4 cwt dissolved bones	...	19	5	0
No. 2.	2 cwt dissolved bones 2 cwt sulphate of potash ½ cwt „ magnesia	... ...	8	16	1
No. 3.	3 cwt dissolved bones 1 cwt sulphate of potash ½ cwt „ magnesia	... ...	9	13	0
No. 4.	3½ cwt dissolved bones ½ cwt sulphate of potash ½ cwt „ magnesia	... ...	10	6	3
No. 5.	4 cwt dissolved bones ½ cwt sulph. of magnesia	... ...	10	13	3
No. 6.	4 cwt dissolved bones	...	9	12	2

From No. 5 it would appear that the ½ cwt of magnesia had increased the crop 21 cwt, but the potatoes in this plot were smaller, and had more disease in the skin than the other plots. No. 4 was the most valuable crop, thus showing that ½ cwt. sulphate of potash was the best proportion of potash to apply.

2nd. Turnips.

The soil of part of each drill was mossy, and part was a poor clay, but the results were much the same in both soils. The turnips were yellow, and no farmyard dung was applied. The artifical manure of each plot, excepting No. 1, was applied at the rate of about £3 per acre.

	Rate per Acre.		Weight of Roots p. Ac. T.	C.	Q.
No. 1.	No phosphates	...	0	8	2
No. 2.	6½ cwt dissolved bones	...	15	10	2
No. 3.	2 cwt bone meal 2 cwt dissolved bones 1 cwt super. of lime	... ...	12	11	2
No. 4.	5 cwt bone meal	...	12	15	2
No. 5.	5 cwt ground phosphates 86·5 per cent.	... ...	12	8	0
No. 6.	7½ cwt ground coprolites	...	11	14	0
No. 7.	7½ cwt super. of lime	...	14	5	0
No. 8.	5 cwt dissolved bones	...	14	10	2

With the exception of No. 2, all the plots were supplied with 1 cwt of sulphate of potash and ½ cwt sulphate of magnesia, and with the exception of Nos. 2, 4, and 8, all had ½ cwt sulphate of ammonia. The soluble phosphates were thus better than the insoluble, and the animal phosphates than the mineral phosphates.

The following, which was a continuation of the above, was tried to find out the best proportion of potash to apply to the turnip crop. No. 8 is the same as above.

	Rate per Acre.		Weight of Roots p. Ac. T.	C.	Q.
No. 8.	5 cwt dissolved bones 1 cwt sulphate of potash	... ...	14	10	2
No. 9.	4 cwt dissolved bones 2 cwt sulphate of potash	... ...	13	15	0
No. 10.	5½ cwt dissolved bones ½ cwt sulphate of potash	... ...	15	6	[illegible]
No. 11.	6 cwt dissolved bones	...	12	18	[illegible]
No. 12.	6 cwt dissolved bones	...	13	2	2

All but No. 12 were supplied with ½ cwt. of sulphate of magnesia, which thus appears to have been of no benefit. The best proportion of potash here, as in the potato experiments, appears to be ½ cwt per acre.—*N. B. Agriculturist.*

PHOSPHATE OF ALUMINA AS A MANURE.

IN a letter, replying to Professor Tanner, who had criticised his opinions as to the value of phosphate of alumina as a manure, Mr. John Milne, Mains of Laithers, Turriff, gives a statement of its effects as ascertained by careful experiment in Aberdeenshire, a county in which the soils are naturally very deficient in phosphates, and therefore better adapted to test their relative value than soils in many other districts.

So long ago, Mr. Milne writes, as 1872 I received samples of four different varieties of Redonda phosphate. These I got finely powered, and commenced a series of experiments on turnips, in large flower pots got for the purpose. In other pots I tried crushed bones and also superphosphate. The soil was thoroughly mixed, but, being poor in phosphates, the non-phosphate pots came to nothing. The Redonda pots were a little better, but, even when applied in large quantity, so little better that I concluded it was practically useless. The pots manured with crushed bones and also with superphosphate produced large turnips. Seeing it to be useless in the undissolved state, I made some experiments with a view to dissolve it in acid, and also tried

the effect of fusing it with soda, potash, and lime, at a red heat, but was unable to turn anything practically useful out of it.

After the experiments of the Aberdeenshire Agricultural Association in 1876, directed attention to the use of ground phosphates, one of our Aberdeen manure manufacturers bought a lot of fifty tons of ground Redonda phosphate, which he sold to farmers. From many of these I got information that it proved to tally useless to the turnip crop, neither could I get one farmer to affirm that it did any good. Few farmers are able to discriminate between one variety of phosphates and another, and the negative results obtained by the trials of Redonda phosphate had a most damaging effect upon the sale of all ground phosphates within the county the following year. This induced the Aberdeenshire Agricultural Association to test the effects of phosphate of alumina.

Experiments repeated eight times give an average increase of 3 cwt. per acre of turnips from the use of phosphate of alumina, 103 cwt. from the use of curacoa phosphate, 98 cwt from the use of coprolite, and so on.

In 1879 the results on eight plots of turnips at the same stations were of a similar character.

The results of these experiments on turnips are summed up by Professor Jamieson, the Association's chemist, to be.—

That phosphate of alumina has exerted little or no influence on the crop.

That phosphate of iron has exerted little or no influence on the crop.

That phosphate of lime has exerted a decided influence on the crop.

In 1878 I conducted an extensive series of experiments on turnips with Redonda and various other kinds of phosphates, on two farms; but the soils were previously too rich in phosphates to give any definite result, although many interesting effects of combinations were brought out.

In 1879 I made a very careful experiment on turnips with phosphates, on poor light soil nearly destitute of phosphate of lime. The crop came up well, but owing to the cold season and the poor condition of the soil, the crop, although very equally planted, turned out light. The experiment was done in duplicate, and the phosphoric anhydride was applied to all the lots at the rate of 100lbs. per acre. The average results were as follows :—

	Tons.	Cwt.	Qrs.	Lbs.
No phosphate	0	6	1	21
Redonda phosphate washed by acetic acid	0	6	0	22
Redonda phosphate unwashed ...	0	9	3	8
Canadian apatite	0	8	3	16
Carolina phosphate (river) ...	2	7	2	11
Cambridge coprolities	2	9	1	21
Curacoa phosphate	2	19	3	17
Navassa Island phosphate ...	3	2	1	25
Bone ash	3	0	2	5
Lacepede guano	4	10	1	13
Coprolites ¼ soluble ¾ insoluble ...	5	8	3	13
Superphosphate	6	3	1	25
Precipitated phosphate... ...	6	11	3	1

These experiments, conducted with the greatest care to secure accuracy, are to my mind, conclusive evidence that phosphate of alumina is 'practically useless;' and I do not think I committed a very great imprudence when I asserted that in Scotland its effects are 'scarcely perceptible either to the eye or the balance.' It would be contrary to all experience to believe that its effects can be different in any other part of the kingdom. At least I shall have to hear of experiments conducted with equal care to secure accuracy, having a contrary result, before I come to alter my opinion. So far these phosphates of alumina have proved disastrous to all importers, manufacturers, and farmers who have touched them. Witness the failure of Peter Lawson & Sons, the collapse of the Alta Vela Phosphate and the Sewage Phosphate Companies; the law proceedings between importers of Redonda phosphate and manufacturers; the hundreds of tons rejected by manure manufacturers, which have been lying in Liverpool for years without a purchaser, until it is getting smuggled away in small quantities only to disappoint the farmer, and tend to bring the whole ground phosphate trade into disrepute.—*N. B. Agriculturist.*

A PEEP INTO A BEEHIVE.

LIGHT a piece of rotten wood or a roll of cotton rags and blow a few whiffs of smoke among the bees, then rap several times on the outside of the hive with a light stick, and wait a few minutes for the bees to fill themselves with honey. A very little smoke will alarm the bees, and with the drumming cause them to fill their sacs with honey. *When gorged with honey or liquid sweets, bees will not sting unless forced to do so.* Some poor chap may have failed in getting sweetened up, so, on opening the hive, the cluster may be sprinkled with sweetened water. This they consider a great treat, and by the time they have disposed of it, are as harmless as so many flies. The buzzing which they make shows that they are as good natured as a company of fat aldermen just after dispatching a roast turkey at some friend's house. The combs may be taken out and handled just as you please, and the bees brushed and scooped all out with little danger.

Three classes will be found to constitute a prosperous colony of bees during the summer season. A fertile queen, a few hundred drones, and about twenty or thirty thousand workers.

The queen is the only fully developed female in the hive. The supervision of the hive and the laying of eggs is her office. She lays during the summer season from two to three thousand eggs each day. A fertile queen is about three-fourths of an inch long, has short wings, a slim, finely tapered body, and in the common bees, is a deeper black in color than the workers. The Italian queen has no yellow bands crossing the body, but is of a golden yellow color. The cells in which queens are produced are conical in shape and resemble a peanut in appearance. They usually project downward from the edges of the combs. About sixteen days elapse from the time the egg is laid until it comes forth a perfect queen. Five days after hatching, if pleasant, the queen flies out to meet the drone and pair. After pairing, she returns to the hive and rarely leaves it during her life, unless she is accompained by a "first swarm." She lives four or five years, but is not usually very valuable after her third year. If the queen be taken from a colony during the working season, the bees are thrown into great confusion, but they soon construct queen cells, place an egg or a larva in each, supply it with royal jelly (the food for the queen larvæ) and thus cause it to be developed into a queen. Upon this one natural principle depend all of the various methods of increasing colonies by dividing them into parts and allowing each part to form a separate colony.

The drone bee is stouter and larger than either the queen or worker, and similar to the queen in color. They appear in April or May and usually disappear during August. They have no sac within their bodies for carrying honey, no pollen-baskets on their legs, and are provided with a sting, consequently they are unable to assist in the labors of the hive.

The drones are the male bees and appear in the hives about the time young queens are being reared in order to impregnate them. When they have fulfilled this office. they are then destroyed by the workers. But one drone is needed to impregnate each queen, but as bees (and nearly all winged insects) pair while on the wing and colonies in a state of Nature are isolated, many males are produced that impregation may be accomplished before the queen in roaming about, meets with any accident. Drones are produced in twenty-five days from unimpregated eggs placed in larged size cells.

The Worker Bees, well known to every one are, undeveloped females having a sac within the body for carrying honey to the hive and baskets on the hinder pair of legs for carrying pollen—the yellow-dust of flowers —which they feed to the young. Wax from which comb is built, secreted by them under the scales of the bodies. It is secreted from honey the same as animals secrete fat from the food they eat. Eighteen or twenty pounds of honey are required to produce one pound of wax, hence, if honey be taken out and the combs returned to the bees, a great saving is made. Propolis or "bee glue" is a substance gathered by the bees from the trunks of trees, and is used in stopping all crevices in the hive and in varnishing the inside surface. About twenty-one days is the time required to produce workers from the eggs. The worker cells are small and when capped do not extend beyond the surface of the comb as do the capped drone cells. During the first two weeks of their existence they work inside of the hive taking care of the brood, &c. The workers live about two or three months during the honey season, and from six to nine months at other times. As they drop off during summer, their places are supplied by others, so that a whole colony, with the exception of the queen, is changed several times in a season. This is shown by substituting for a black queen fertile Italian queen. The young bees produced will have the yellow bands, and in a short time the whole colony will be ent rely changed.

A whole volume might be written about those wonderful little workers. —*American Paper.*

WONDERFUL LIGHTS IN NATURE.

WHILE prospecting on a spur of the mountains near Mesilla, New Mexico recently, one of a party of miners noticed in wrenching his pick from the loose rock a cold current of air. Another blow laid bare a cavity, and a determined assault on the broken shale soon shewed an opening or passage that led unto the rock at a downward angle of about forty-five degrees. The hole was enlarged, and found sufficient to admit a man's body. Several lighted pieces of brush were hurled in, and three of the men, steadied by a lariat held by the others, started down the tunnel under the mountain. The passage was rough and uneven, and about four feet high, and, after thirty feet, suddenly turned to the left. A candle was lit, and by its light they found twenty feet further a large hall—a hall of pillars so completely was it filled with long, delicate columns, reaching from the floor upward out of sight. They were stalactites hanging from the walls in endless variety, while from the floor rose rich stalagmites meeting them and forming figures of all conceivable shapes. Water dripped from above, showing that the work of column-making was ever going on, while a death-like chill did not add to the comfort of the surroundings. The men were about to venture into the labyrinth, when the one holding the candle slipped and dropped it. Nothing could be done but follow the lariat back, but as their eyes became accustomed to the gloom, a curious phenomenon appeared. In various parts of the cave luminous spots of light were seen. Some near them gave out fitful flashes of flame, while others seemed like moons, glowing with a peculiar pale yellow light, others again were of irregular shape, that made the darkness more apparent. Every move revealed new wonders. Oval balls of light, blazed from behind the columns, confronting them at every step, while as far as they could see, gleaming and sparkling, the mysterious lights appeared, making the cavern a realisation of the old tales of enchantment. One of the men struck at one of the growing spots, and knocked it down. Carefully taking up the object, that still glowed but gave out no heat, they felt their way into outer air, only to find that they carried an insignificant toadstool, a fungus

that lost its glow in the daylight. The subterranean plant, for such it was, is generally found in mines; and is known to science as the *Rhizomorpha subterranea*; and is allied to the edible mushroom.

Many of our native flowers, especially the yellow and bright-tinted ones, such as the sunflower, marigold, &c., have often been observed giving out minute flashes of phosphorescent light soon after sunset, while the exhibition given at times by the oriental poppy probably by the oxidation of some hydro-carbon it secretes, is extremely wonderful. Poke weed, at certain times, gleams with a rich greenish tint, and explains some of the mysterious lights that are often seen by the believers in ghosts.

A Brazilian plant, the cipo, makes a wonderful display of pyrotechnics. When bruised or cut it gives out a milky fluid that at night blazes with light for hours. Certain tribes in the interior use it in some of their rites. A certain number of captives taken in battle are decapitated and their heads tanned by a secret process that leave them like polished leather. The eyes are replaced with peccary teeth, bending outward, while the mouth is also ornamented in a similar manner, giving the head a most ferocious appearance. The long black hair is allowed to hang loose, and the flesh around the neck is carefully drawn together, forming a socket. Into this is inserted the end of a long pole. The head is then decorated with fantastic tassels of various kinds, and a string attached to the chin. At nightfall the whole is set off with the luminous milk of the cipo. The pole is raised and planted, and the head kept moving by the wind and a liberal use of the string. Its ghostly appearance, glowing with a reddish light, would undoubtedly frighten the evil spirits, if there were any, as that is its purpose.

All who frequent the seash ore are familiar with the fiery appearance of the sea at certain times. Innumerable animals are contributing their vital forces to create the display, and in the warmer climates the water seems a mass of living flame. Every inch of its surface is alive with minute jelly-like creatures that, according to some writers, possess a peculiar secretion in glands for this purpose, and in proof of this, several of these animals were placed in clear water in a glass, which instantly became phosphorescent, the light-giving medium thrown out from the animals permeating the water in every direction. Larger jelly fish often shew this phenomenon. When at great depths they appear like great moons rising and falling. One of these creatures was observed off Nantucket of gigantic size. The finder was sculling his boat along in deep water after nightf all, and saw what appeared to be the reflection of the moon, although the moon was not up. Drawing nearer, the seeming reflection assumed the shape of an immense ball of light, while extending from it, as far as the man could see, innumerable filaments and streams of flame issued. With great undulations the ball moved, dragging its fiery tail like a veritable comet, and, reaching the surface, showed itself a gigantic medusa, the Cynea. It was more than six feet across, and, judging from the length of the tentacles at more than 150 feet. Mrs. Agassiz describes one even larger that she observed off the rocks at Nahant, a famous place for displays of marine phosphorescence. The waves beat against the rocks on summer nights, splashing into the caverns and leaving them dripping with dazzling scintillating drops of fire. As the rollers come in, their tips seem to ignite spontaneously. Now running along the crest, the light deepens, growing as the wave comes on, and finally seems to burst its watery bands, hurling itself on the shore in a shining mass of molten silver.

One of the most remarkable instances of phosphorescent light appearing on living creatures is found among the herons. Among the keys and the extreme end of Florida, these birds are found in countless numbers. Mullett fishermen and sportsmen have often noticed peculiar dim lights standing motionless over the water among the mangrove thickets. They were discovered, however, to depend on the presence of the birds. When they were approached in the dark, the flapping of wings as a crane flew away would be the last of the lights. The writer has examined many of the birds, especially the 'Ardea Herodias,' or great heron, and found on the breast a spot about as large as the open palm, where the feathers are covered with thick yellow powder, that is easily shaken off, and evidently exudes from the body at this spot as a secretion drying into a power when exposed to the air. The bird stands motionless in the water, and the spot is undoubtedly used for, or accomplishes the end of attracting the smaller fishes within reach of the bird; and, if it is a decoy, it is a most remarkable provision of Nature.

Many fishes are ornamented with rows of fiery spots that gleam and sparkles as they rush through the water. The so-called fireflies of tropical countries afford interesting examples of this wondeful faculty. If the luminous spot that glows with seeming white heat is examined under a glass, it will be seen that the yellow tissue is made up evidently of fat globules that are intersected by many delicate veins or trches that contain air, and the light may be explained by the union of the carbon of the fat and the oxygen of the air thus introduced, which produces a slow combustion without increase of temperature. That this is possible is proved by the successful experiment, within a few weeks of Mr. Kerdig, a Hungarian. He uses mineral substance in a liquid form. He pours a quantity of the fluid on his hat and calmly sets fire to it. A mass of lurid flames rises instantly almost to the ceiling, but M. Kerdig, in no wise disconcerted places his hat on his head, and waits until the flame gradually dies out. He then exhibits the hat triumphantly to the audience. It is uninjured. He next sets fire to the floor, then to his handkerchief saturated with the substance, and finally goes so far as to pour some of it into the palm of his handand light it but the floor the hand kerchief and the hand are unharmed. The vapor of the mineral substance possesses considerable expansive force, so that in reality it is the vapor which burns and not the liquid. This may explain the curious lights that are frequently seen floating over the sea especially near Block Island, and considered phantom ships by many of the superstitious islander. Such lights are undoubtedly caused by the gases arising from the millions of mossbunkers that are found there in schools, the gas becoming luminous at times when coming in contact with the oxygen of the outer air.

It has been observed that the lights when abdominal as in our firefly are involuntary while in those insects that show thoracic gleams. its appearance seems subject to the will of the animal. An interesting case of the latter is seen in the 'cucujo' or pyrophorus of the West Indies, a beetle two inches long. The light issues from two oval spots on each side of the thorax, or fore part of the body, and when at rest the spot gleams with arid yellow glow, but when in the air it assumes a dark red appearance, and with thousands of them flying through the air the sight is extremely beautiful. The writer recently secured a beetle of the genus elater through the mail from Cuba, and after its long voyage it had lost none of its power. The light was so powerful that it cast a shadow on the wall at a short distance and when placed on a hook and irritated it could be read from the light although, of course disconnectedly. A dozen confined in a glass would give ample light for reading. Ladies use them as decoractions for the hair in southern countries, the bright gleams of red, blue, and yellow being exceedingly effective.—*New York Paper.*

THE POTATO DISEASE: ITS NATURE AND ORIGIN—CAN IT BE CURED?

THIS was the text of a discussion opened by Mr. G. H. Stevens of Gullane, at the meeting of the Haddington Farmers' Club last Friday; and my reason for offering a few observations on the subject is, that I notice he has fallen into the once popular error of supposing the potato disease to be caused by an insect. He goes on to say that it was "ent omological, an insect destroying the plant," and further, that he was "supported by such men as Professor Tyndal and Professor Huxley. I was not aware that those eminent savants took this view of the potato disease. I know that, more than thirty years ago, Mr. Alfred Smee, then Surgeon to the Bank of England, attained to fame by publishing an article in the *Illustrated London News*, proving, to his own satisfaction, and thousands besides, that the disease was caused by an insect, and giving an engraving of potato shaws with magnified insects on them. Such interest did the matter excite, that 50,000 extra copies of the paper were sold that week. The name he gave the insect was "Aphis devastator," Yet he was quite wrong, as Mr. Stevens is now. No doubt he found a potato leaf with aphis on it, as he might have found them on a rose leaf, or any other leaf.

Such mistakes would be of little importance were it not that if they are accepted, they lead in the wrong direction in search of a remedy; and the potato crop is of such vast importance to the nation that no opportunity should be lost of arriving at correct conclusions—first, as to what the disease is; second, as to the mode of its attack and development; and lastly, the direction in which a remedy must be sought for its amelioration, if not its complete prevention, which latter, I fear, is beyond the power of man.

In the first place, then, let me say that the potato disease is a parasitic fungus, a vegetable and not an insect, as has been proved over and over again—as, for instance, by Mr. Worthington Smith, who has exhausted the subject from this point of view. it has the habits of fungi of other descriptions with which gardeners especially are familiar. Take, for instance, the mushroom. This fungus has what may be termed its resting spore, which, if kept cool and dry, will remain quiescent for years, but when placed in soil of suitable texture and warmth, it "runs," as the gardeners describe it; but even then, the full development of the plant does not take place unless the soil is watered and the temperature of the house is, as to heat, and especially moisture, considerable when mushrooms appear in a night as if by magic. Now mark the mode of attack of the potato disease. The resting spores being in the soil enter the potato through the spungioles of the *roots*, say in *June*, and they "run" in the interior of the cellular tissues of the plant, but remain quiescent till warm showers lead to their rapid development in July or August; and we find black spots on the leaves generally first, but also we find destruction of the tissues of the tuber going on at the same time. This is caused by the full development of this mysterious plant, the potato fungus. It can be seen by a microscope fully developed on the back of the leaf as well as in the potato. I have myself checked its progress on the back of an individual leaf by the application of sulphur; but it is not practicable to apply such a remedy to any considerable number of plants, and if it were, it would not check the ravages of the disease in the tuber. Its habits are also exactly the same as the vine mildew, and what is called dry rot, which is nothing else than the ravages of a fungus that makes rapid strides in growth when it is favoured by being subject to a stagnant, warm, and moist atmosphere.

I now come to the last head I proposed—*viz.*, to indicate the direction in which amelioration may be looked for. I am of opinion that nothing that man can do will effect a complete cure. The spores may die out as mysteriously as they made their appearance, something the same as the vine mildew has done in this country under a more rational system of vine culture. Thirty-five years ago the vine mildew was rampant in hundreds of vineries in the neighbourhood of London. The practice then was to syringe the vines with cold water every evening during their growth, till the fruit began to colour. When the houses were shut up in the evening, they had an excessively damp atmosphere. When this treatment was reversed, and no water applied to the vines after their buds burst, as is now the practice of the best cultivators, the vine mildew disappeared almost, but not entirely. A return to the old system of management would bring it into full vigour at any time. Here, then, I think there is a lesson anent the potato disease. We cannot prevent the rains falling on the potato fields, as we can in the case of the vines; but we can plant them on well-dried land, and, as plenty of ventilation was found to check the vine mildew, we can plant them on airy, open, well-exposed fields, away from woods or high hedges, and especially much wider apart from drill to drill, as well as from plant to plant, than is at present the custom; for I am certain that, next to bright dry weather in July and August, nothing checks the disease more than plenty of air. I have seen the shaws of diseased potatoes being ploughed into the land which is just spawning the soil, to be ready to produce another crop of the disease whenever potatoes are planted on it. They should invariably be burned. Sulphur, when it can be applied to the smaller class of fungi, as it can to that of the vine leaf, is rapidly fatal to them; but how to apply it to the potato is another question. Some writers advise that the moment the disease makes its appearance, the tops should be cut off. This is utter folly; the disease is already in the tuber as well as in the shaws, and will run its course. The best plan to adopt is to let them alone till the disease has run its course, which is generally by the time the cold weather of October sets in, when they can be separated, the diseased from the sound, at once. They should afterwards be kept cool and dry, under which conditions the disease can make no further progress, for a certain temperature is necessary for its development.

The disease that is at present decimating the French and other vineyards is not a fungus but an insect—the *Phylloxera vastatrix*—a disease that might have been coped with successfully, had the Government of France acted on the suggestions of practical men in this country, made to it fifteen years ago. It is now too late. The potato disease is from its very nature less under man's influence.—*W. T. in Scotsman.*

OUDH TALUKDARS' AGRICULTURAL MEETING, 1881.

THIS is an account of the first of an intended annual series of meetings to be held at Lucknow, under the auspices of the talukdars, with the view of promoting the interests of agriculture introducing improved methods of cultivation, and developing the economic resources of the province. It had been intended that the first meeting should be held in the spring of 1880, but, owing to causes which could not be foreseen, it was found necessary to postpone it till the following year.

2. All the arrangements connected with the meeting were made by a committee of management, consisting of 16 members, 15 of whom were native gentlemen. The committee met publicly on each day of the exhibition for the discussion of various subjects of interest, among which were:—The possibility of the extension of irrigation by the action of the talukdars or of the Government, or of both, and the means by which such extension could be effected: the feasibility of improving the breed of cattle and the means by which this object could be best attained: the improvement of ploughs, the advantages of thin sowing, and the extension of arboriculture.

Papers on these and cognate subjects were read by various gentlemen, European and native; and the proceedings (which were conducted entirely in the vernacular) were watched with intelligence and interest by a large number of persons chiefly those interested in the land.

3. The exhibition comprised the following classes:—

(1) Cattle.

(2) Agricultural implements.

(3) Grain and other agricultural products.

(4) Arts and manufactures.

4. Prizes and medals were awarded to the successful exhibitors, after careful inquiry and comparison by selected judges. The expenses incurred in connection with the meeting amounted to Rs. 11,039; the amount being met by a Government grant of Rs. 3,000 by Rs. 6,000 realised as subscriptions from the Talukdars and others, and by the sale of tickets.

5. The Lieutenant-Governor and Chief Commissioner congratulates the Talukdars of Oudh on the results of this their first agricultural and industrial meeting. A satisfactory beginning has been made in starting a series of such meetings, which it is hoped may be instrumental in effecting a permanent improvement in the agriculture and general industry of the province. The valuable information contained in the papers read on this occasion and the free and intelligent discussion of the subjects which followed can hardly fail, his honor thinks, to be of use in exciting an interest in agricultural and economic subjects, which has hitherto been but imperfectly manifested.

Sir George Couper trusts that these meetings will now be of yearly occurrence; and that the Association will be able in future to fulfil its purpose in regard to them without any direct aid from Government beyond the recognised subsidy for cattle-prizes. What his Honor wants to see the talukdars of Oudh taking a direct and personal interest in the matter; profiting by the information gained; practising the agricultural improvements brought to their notice; and thus helping on the economic progress of the province.

RESOLVED.—That these remarks be communicated to the Secretary to the Oudh Talukdars' Agricultural Meetings, for the information of the Talukdars; and that a copy of this Resolution be published in the *Gazette.*

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

The Monthly General Meeting was held on Thursday, the 21st April, 1881.

W. H. COGSWELL, ESQ., *President, in the Chair.*

The proceedings of the last monthly meeting were read and confirmed.

The following gentlemen were elected Members:

The Manager, Rajmai Tea Estate, Assam; Col. A. W. Twiss, Messrs. O. G. R. McWilliam and E. A. Roussac.

The names of the following gentlemen were submitted as desirous of joining the Society:—

A. H. Collins, Esq., C.S., Assistant Commissioner, Hazareebagh,—proposed by Mr. F. Wilcox, seconded by Mr. H. A. Firth.

T. C. Pande, Rajah of Pakour,—proposed by the Secretary, seconded by Baboo P. C. Mitra.

W. Innes, Esq., Deputy Traffic Superintended, E. B. Railway,—proposed by Mr. W. H. Cogswell, seconded by Mr. W. Stalkartt.

Alfred Bridge, Esq., Calcutta,—proposed by Mr. R. M. Daly, seconded by the Secretary.

Lieut.-General Dhoje Nursingha Rana Bahadoor, Nepal,—proposed by the Secretary, seconded by Baboo P. C. Mitra.

J. A. Anderson, Esq., Merchant, Calcutta,—proposed by Mr. Cogswell, seconded by M. W. Pigott.

T. S. Anderson, Esq., Merchant, Calcutta,—proposed by Mr. Cogswell, seconded by Mr. Pigott.

The Secretary, Public Garden, Baugulpore,—proposed by the Secretary, seconded by Mr. S. H. Robinson.

H. E. M. James, Esq., Bombay Civil Service,—proposed by D. R. Lyall, seconded by Mr. A Wilson.

James Paterson, Esq., Merchant, Calcutta,—proposed by Mr. Cogswell, seconded by Mr. Stalkart.

T. H. Kerswill, Esq., Khoreel Tea Garden, Cachar,—proposed by Mr. W. Aitchinson, seconded by the Secretary.

Rejoined.—W. C. Plowden, Esq., C.S., Simla.

CONTRIBUTIONS.

1. Report on the Government Botanical Gardens, Saharunpore, 31st March, 1880. From the Superintendent.
2. Transactions Asiatic Society of Japan, Vol. IX. Part 1. From the Society.
3. Proceedings Asiatic Society of Bengal, for February, 1881. From the Society.
4. Proceedings Agri.-Horticultural Society of Madras for March, 1881. From the Society.
5. Memoirs, Vol. VI. and Proceedings Vols. 16 to 19 of the Literary and Philosophical Society of Manchester. From the Society.
6. Catalogue of Plants in the Royal Botanic Garden, Mauritius. From the Director.
7. The Tea Cyclopædia. From the Editor.
8. Seeds of Amherstia nobilis from Moulmein. From Major R. W. Fanshawe.
9. Seeds of Cupressus of three kinds, from the Botanic Garden, Saharunpore. From the Superintendent.
10. Seed of *panicum spectabile*. From the Agri-Horticultural Society of Madras.
11. Seed of Bamia cotton, and a specimen of the cotton. From W. F. Westfield, Esq.

Mr. Westfield mentions that this cotton (9 tolas) and seed (26 tolas) is the produce of one plant grown in a large pot on the terrace of his house; the plant is two year's old. The cotton is pronounced equal to ordinary Egyptian. The seed had germinated freely in the Society's Garden.

Mr. R. B. West sent for exhibition a healthy well grown plant, in full flower of *Hæmanthus cinnabarinus* a new variety, introduced in England in 1879.

GARDEN.

The Superintendent's report was submitted. The following are extracts:—

The weather has been very trying and the garden labour has been fully occupied in artificial watering but the showers of the 14th, 15th, and 19th current, released the men for other urgent work. Begonias and other delicate plants have suffered much from the heat.

The manure presented by Mr. H. A. Firth is leaf mould strongly ammoniated. The bed to the south of west tank, mentioned in preceding report as the spot were some imported Rose plants had been planted out was freely manured with it; the first effect was to produce a minute insect which almost destroyed all the leaves, but in a very short time the insects disappeared, and the plants have the healthiest appearance in the garden. Mr. Firth has also presented to the garden 15 Stephanotis floribunda and a quantity of Combretum seed; this latter will be reported on hereafter.

On the morning of the 19th instant, the plot of ground on which tomatoes were grown, was ploughed up by Mr. Stalkartt's plough, the ground was rather stiff, the last fall of rain having been on the night of the 15th instant; the furrow was 5 inches deep by 14 inches wide, the ploughman and bullocks working with ease, and without any special strain. I prefer this to any of the other ploughs that I have yet tried in the garden, as from its peculiar construction and operation, the entire ground passed over is disintegrated, and has also the advantage of being adapted to different size bullocks. The cost seems rather too high for the ordinary agriculturist. Mr. Stalkartt says this can be modified, so as to bring it within their means.

The demand for fruit grafts appears to be increasing and I would recommend preparation being made in time for grafting operations on a large scale.

The present system of drainage is defective, and as opportunity offers will be improved, so as to augment the tank supply. Caladiums have sprouted, and are now making a fine show. Out of the lot of Rose plants received from Mr. Bull on the 26th ultimo, 92 are doing well, 28 are likely to recover, 82 dead. There is very little else for special report, but I take this opportunity to allude to the following donations to the garden :—

Phalænopsis, several varieties presented to the garden some time since by Col. W. M. Lees, have been transplanted from their original boards, where they were rather too thick, and have given quite a gay appearance to the temporary Orchid House, as the flowering has been constant and abundant.

Avocado Pear seeds presented by Col. Lees ; germination very fair, and plants doing well.

White Pumplenose seed presented by Mr. C. E. Blechynden ; germination good, plants doing well.

Mignionette seed, presented by the Secretary ; splendid germination, and large quantity of seeds collected from plants.

Several varieties of acclimatized flower seeds, presented by Col. H. R. Wintle, results good, both as to decorating the garden while in flower and out-turn of seed.

Mignionette seed presented by Mr T. M. Francis ; results in flower and seed admirable.

From Mr. W. Galiffe, 2lbs. Arabian Coffee seeds ; germination capital, plants are very healthy and ready for issue, these plants seem admirably adapted to the climate of Bengal.

Musa seed from Herbert River and *Cassia magnifolia* germination very fair, and plants are likely to thrive. Presented by Mr. A. L. Bernays. Several varieties of *eucalypti* seed contributed by the same gentleman, none of these have germinated yet. I may observe that some time since, I noticed a plant of *Eucalytus globulus* at the Entally Orphanage some eight feet high as well grown as any I have seen in Australia. I mention this as I believe they have not been found to succeed in Bengal. Five varieties of Maize presented by Mr. C. Girdlestone from Nepal have germinated and will be planted out shortly.

Nurma Cotton seeds presented by Capt. Pogson have germinated very well, and will be further reported on hereafter.

Amherstia nobilis seed presented by Major Fanshawe. None have germinated for reasons already given in previous garden report in May 1880, but I think another attempt should be made to propagate this very handsome plant by seed, and with the next lot received a different treatment than has hitherto been observed, will be tried.

Bamia Cotton seed presented by Mr. W. F. Westfield has germinated well, will be planted out and reported on hereafter.

Layering of Rose plants begun this day.

Particulars regarding the Sirgooja or Ramtil.

The Secretary placed on the table a copy of the *Calcutta Gazette* of the 13th April, containing an account of the "cultivation of the Sirgooja plant in the Nuddea district." This plant is said "not to be an indigenous product of the Nuddea or any adjacent district, but is reported to have been brought originally from Chota Nagpore, where it is said to be in extensive cultivation." It was introduced into the Nuddea district about 30 years ago.

The subject of this oil-yielding plant has attracted the attention of the Society of various times during the past 30 years. It was first brought to notice by a then Member (Mr. T. M. Robinson) in 1849, when resident at Ranchi. Mr. Robinson sent a specimen of the seed, and stated that its oil is used for food by the poorer classes all over Chota Nagpore, who raise it in large quantities for this purpose. He thought that this seed would yield more oil than an equal quantity of any other he had seen, owing to the extreme slightness of its skin.

This seed at the time alluded to was produced in Burdwan, and also in Beerbhoom, Midnapore, and other districts of Bengal, where it is employed for the same purposes as in Chota Nagpore. Colonel Sykes had previously reported the plant to be cultivated also on the other side of India, though under another name "karleh," (*An account of the cultivated oil and cordage plants of Dekhen*). Experiments were made by Mr. E. Solly with this and other Indian oil-seeds some thirty years ago, which shewed that it yielded about 35 per cent. of oil or 10 per cent. less than Til-seed (*Sesamum orientale*), known in commerce as the gingelie oil.

This seed is identical with the Niger seed of commerce, and is largely imported into England under that name from the Western Coast of Africa. It is also exported from Calcutta, but being included with several other oil-seeds it is difficult to say the quantity that has been recently shipped.

It was subsequently reported to the Society, that the Sirgooja cake was unfit for cattle feeding owing to its horny excrescence, and could only be used for manure. This has, however, been since overcome, for it has been so excoriated that cattle can be fed on it without causing any injury.

The Sirgooja or Ramtil is the *Verbesina sativa* Roxb: *Ramtilla oleifera*, Wight : *Guizotia Abyssinica*, Cass.

The original sample presented by Mr. Robinson in 1849 was placed on the table, as also a sample of the oil presented by Baboo Peary Chand Mittra in 1852.

The export of Sirgooja seed is trifling as compared with other well known oil seeds, such as Lin, Poppy, Rape, Til, and Castor. The export from all parts of India of these seeds during the official year 1880-81 may be valued at about six millions sterling. It would be very desirable if a large proportion of this seed could be converted locally into oil and exported in that shape, seeing how much would be saved in freight. Moreover, the refuse for manure and cattle food would be most valuable, especially for the latter purpose, when so many thousands annually die from want of nourishment.

The Curative Properties of Euphorbia Pilulifera.

The Secretary next read the following note by Mr. P. Doyle, C.E., dated from Queensland, 12th February :—

Euphorbia pilulifera is the botanical name of a plant occupying public attention at present in the Colony as a specific for diseases of the chest. The plant is only known by its scientific appellative. For technical description, see *Flour Australiensis*, Bentham and Mucker, page 51. It is a very common tropical weed, procurable in India and Burmah. Once seen, it is easily distinguishable from other plants. When broken the stem yields a white viscid liquid, very acid in taste, possessing strong emetic and corrosive properties. The Euphorbia family has a great many varieties. Some grow in Europe, but it is only in tropical regions that the poisonous varities are found. The plant referred to has in some cases a bronzed appearance, nearly resembling "pig-weed," but not having the fleshy leaf of that plant. Its seeds are in small knobs close to the stem. The decoction has not only been found efficacious in pulmonary affections, but its curative properties extend to other disorders. Being a poisonous plant, it should be used with caution.

Notice respecting Gossypium Arboreum or Tree Cotton of the Deccan.

The paper next submitted was from Capt. J. F. Pogson, on the above subject.

By this post, I have sent to your address, for valuation, and subsequent submission to the President and Council of the Agri.-Horticultural Society, a sample of seeded cotton wool, of the "*G. Arboreum*," raised at Saharunpore, in the Government Botanical Gardens, under the Superintendent, Mr. J. F. Duthie, F.L.S.

I have ever since 1869-70-71, advocated the introduction and cultivation of this valuable cotton producer, and in 1871, whilst at Kussowlee you were so good as to send me a supply of the seed, obtained from the Deccan.

I am not quite certain but to the best of my recollection I sent a portion to the Officer then in charge of the Saharanpore Botanical Gardens, and with whom I had been in correspondence on the subject of grafting the "Ficus elastica," on the "*Banyan*," tree or "Ficus Indica," (I sent some of the seed to two friends residing in Umballa, but I never heard of the result of their trial), and it is by no means improbable that the cotton now sent, is derived from trees raised from the seed alluded to.

The fact, that the cotton tree of the Deccan will grow in Upper India having been undeniably established, I think the ventilation of the subject, through the Proceedings of the Agricultural and Horticultural Society, will have a most benificial effect, and lead to its general introduction into the Doon, and all places, where sugarcane is known to flourish in the N.-W. Provinces.

In the Punjab, I am certain, that if properly introduced under official sanction, the cultivation of the "Gossypium arboreum," would be found a very profitable undertaking.

I would suggest, the "Chunga Munga," Fuel Plantation, as a good locality for forming a Government Cotton Tree Plantation and Nursery for the distribution of plants to all applicants.

The seeds sown in beds, would soon yield an ample supply of seedlings, and these when sufficiently advanced, could be planted out in all directions, where space could be found between growing trees. The transplanting operations if carried out during the rains, would meet with success, and thereafter the plants would soon be able to take care of themselves, for this cotton being a sunplant, will not need irrigation after being once fairly established, and as it will bear cotton wool pods, within twelve months, and yield them for nine months out of the twelve and do so year by year for twenty years, every thing is in favor of its introduction. As "kunker" which will yield lime, (chunam), when burned, is procurable in most parts of the Punjab, it should be used as a mineral manure for the Gossypium arboreum seedlings. The "kunker," should be reduced to coarse powder, (without being calcined), and two seers of it should be mixed with the soil, excavated for putting down a seedling. Thus one maund of "kunker" powder would be needed for every twenty Gossypium arboreum seedlings, and this manuring should keep the tree well supplied with carbon for at least ten years, when a fresh supply might be applied and dug in. The yield of cotton wool would very soon cover all outlay for preparing the excavations for seedlings and "kunker" manuring, and thereafter 75 per cent. of the produce might be put down to profit, and 25 to cost of collection, packing, cleaning, and transit. As the plantation is preserved, and is well stocked with game, hares may be present in numbers, and if so, thorn bushes will have to be put around each seedling till sufficiently grown. This will keep off deer, and antelope as well.

I do not think the Officers of the Forest Department would object to the introduction of the G. arboreum, and it would go far to make the Fuel Plantations more than self-supporting. I would recommend the utilization of convict labor for digging the holes, and pounding the "kunker," so that the actual outlay would be very trifling.

To private parties, being landed proprietors, I would recommend the regular formation of "Gossypium arboreum," plantations, one hundred and sixty trees being allowed to each acre. When the trees are sixty feet in height, the land between them should be ploughed, and manured preparatory to being sewn, or planted with ground nuts, *i.e.* "*Chena Boodum*," or "*Moong Phullee*." (Arachis hypogea) and I venture to predict, that if "kunker" dust, or any sort of limestone reduced to powder, be freely used as a mineral manure, that heavy crops of cotton, wool, and ground nuts will annually be secured.

In conclusion I would wish to mention that from March 1879 to present date (March 1881,) I have regularly used limestone reduced to powder, as a mineral manure for vegetables, and fruit trees, and have

found it most valuable. In the spring of 1879, I put down a seedling flat, or China Peach, about 3½ feet in height, it is now nearly twelve feet in height, and well supplied with flowers. This year's growth has yet to commence.

I used a soft limestone rich in fossil shells as a manure and with it was mixed calcined bones reduced to powder and moistened with water holding saltpetre in solution. Peaches are rapid growers, but as the other five seedlings, (I had the sixth given to me,) are nowhere in comparison, the growth is beyond doubt due to the lime-powder. The stone was not fired.

The Secretary stated that a few particulars regarding this fine description of cotton were communicated to the Society many years ago (1842) by the then Agent to the Governor-General in Bundelcund. The seed received from Capt. Pogson has germinated most freely in the Society's garden (see Superintendent's report above) and will be carefully attended to.

It was agreed that a copy of Capt. Pogson's paper be sent to Dr. Brandis, Inspector-General of Forests.

Remedy for Cattle-Disease.

Letters were read—

From Messrs. Octavius Steel & Co. apply for seed of the Potentilla, the leaves of which are stated to be a remedy in certain diseases of cattle (see Mr. Lennox's paper in recently published Number of the Journal Vol. vi. Part 3).

From P. DeLaval Lennox, Esq., of which the following is an extract:—

"Yours of 9th instant. I have begun collecting Potentilla leaves for drying. I suspect I shall be at least a week collecting enough for a 5 lb. packet, having only my son to put on the work. Every available Aryan is "on leaf" in the Tea Plantation, though sorry any one's cattle should be afflicted, for *myself*, I am glad there is a Tea Garden with virulent cattle-disease on it, where the efficacy of the Potentilla may be fairly tried, and I hope fervently that it will be found a real cure.

It is heart-breaking work having to do with natives, especially Hindus, in such a matter as cattle-disease. One will not tell another the medicine for fear of destroying its efficacy on his own cattle while ill. Another whose cattle have been (so it is told to me cured, does not care one iota whether his neighbour's cattle live or die. As cattle and persons residing with them at the time of the disease being ascertained to exist there are put into strict quarantine within the particular homestead. Brethren or relatives outside, must either remain far outside, or submit to quarantine along with the rest if he goes near the place to talk with his people. No one will report the disease for fear his own cattle will fall ill though mentioning its name. Each man will tell the *sahib* that the medicine worked wonders, and tell his own people that the recovery of the cattle was not due to the *sahib's* medicine, but to some holy water or "muntra" or "Jhup Sup" of his Gooroo or says "it will live or die according to fate" and so forth, till one feels utterly uncertain. Even Tehsildars go on the principle "it is necessary to send replies according as it may seem desirable to the district or zillah officer."

The Palampur Tehsildar tells me that lately the Potentilla has been effecting many cures up in Kulu, so its Tehsildar reports.

The Palampur Tehsildar says also that the Potentilla has really affected wonderful cures to his personal knowledge. I asked him to tell me the real truth without fear or favor as he could get neither promotion or reduction from one who is only a Tea Planter, and I think he did speak the truth, and I know does try to get the people to use this remedy by all the persuation in his power: but your Tea Garden applicant will, I feel sure, give an unbiased report, whether effective or the reverse. All I want is the real fact so that if it is good I may be able to work stronger in its favour and if non-efficacious avoid making a fool of myself and other about it.

I am to-day despatching about 1¼ oz. of Potentilla seed, not the wild edible strawberry, to you by to-day's post, and if they germinate and grow shall esteem it a great favor if you will let me know the classification and nomenclature of the plant so that in writing about it its identification will be certain.

From Captain Pogson, in reference to the following:—"At page 160 of Vol. vi. Part iii. of the Journal"—writes Captain Pogson—"there appears the following from Mr. F. Tucker, Assistant Commissioner. "I on the same date sent one (a special) to the Mundi Rajah, from whom the Sukeyt Rajah had been asking what is this:—"*Ishtawurbhu-ri-Danai.*" This long word is only Paharee corruption of the English word "Strawberry" and a note to this effect would be useful in the next proceedings. We have two kinds of strawberry growing wild. The Alpine, on Huttoo and Narkunda, and the common wood strawberry, all over the jungle."

Monster Pumpkin of South America.

Read another letter from Captain Pogson in reference to the large pumpkin of which he sent seeds last year and which were distributed but of which, unfortunately, no record was kept. "I should be much obliged" writes Captain Pogson—"if you would insert a short paragraph in the next proceedings on the subject of the "maha kuddoo," and as I am much in need of some of the seed grown last year, it might thus be forthcoming."

MINERALOGY.

THEY are beginning work in right earnest now in connection with the Wynaad gold-fields. Mr. Brough Smyth was a passenger from Australia, with two assistants he brought out with him, by the last mail steamer; and both the *Cathay* and the *Hydaspes* brought out a lot of heavy quartz crushing machinery, which have been sent on overland from Bombay. The question of a payable gold-field will now probably soon be decided.

THE report of the Directors of the Wynaad Gold Mining Company for the quarter ending 31st March is written in a very hopeful strain. One piece of good fortune is that, whereas the Company purchased an estate estimated to contain about 1,000 acres, it turns out, on survey, to contain 1,614 acres. There is reason to believe that the whole of this property is auriferous. Some inquiries that were necessary as to the validity of the title which the vendors could give have delayed the completion of the purchase, and therefore, the commencement of actual mining operations, but the Directors are satisfied as to the strength of the title, and the Company will soon be fully at work. The estates bordering on the Hump estate, and containing reefs which run into it, have been proved to be highly auriferous, and the shareholders of the Company appear to have good reason to take a sanguine view of their prospect.

ACCORDING to figures furnished by the American Mint, the mines of the United States have produced during the last seven years about £56,000,000 of gold and £54,300,000 of silver, an average production during that period of £8,000,000 of gold and £7,750,000 of silver per annum. About 95¼ per cent. of the silver found its way to the mints and assay offices to be converted into coin or bars. The Director of the Mint, from a careful consideration of all the data at his command, estimates that the amount of domestic bullion used in the arts and manufactures during the last fiscal year was about £1,100,000 of gold and £800,000 of silver, and that the total consumption in all forms was about £2,000,000 in gold and £1,000,000 in silver.

THE quantity of silver which has been extracted in England from the pyrites imported from Spain, has been 18,000 ounces, and of gold about 700 ounces. A new industry has thus arisen from a product which no one suspected a few years ago to have any merchantable value. We receive the largest quantity of pyrites imported (about 450,000 tons) from Spain and Portugal. This crude ore reaches a value of over £1,000,000, and from the burnt ore, sulphur, copper, and oxide of iron or rouge is obtained.

THE prospectuses of seventeen Gold-mining Companies were issued in London during the quarter ending the 31st ultimo, The proposed capital amounts to £1,362,000 in £1 shares. The names and amount of issue of the Companies are as follow:—

Akankoo ...	£67 000	Indian Trevelyan ...	£60 000
California ...	87 000	La Concepcion ...	75 000
Oarta Para ...	50,000	Madras ...	80,000
Oherambadi Dit ...	50,000	Needlerock Este. ...	58,000
Asn. of Canada ...	250,000	North Ooregum ...	40,000
Great S. Mysore ...	39 000	Organoz G. Mines ...	15,000
Guayana ...	250 000	Quartz Hill ...	105 000
Haven ...	50 000	Tambracherry ...	55,000
Hoover Hill ...	40,000		

IN his recent inaugural address as President of the Society of Engineers, Mr. Horsley said that the modern saving in coal in pig-iron making in the foundry, and the enormous saving of fuel in steel-making, is to a great extent the cause of the increasing surplus of coal throughout the country. Mr. Hunt's figures show that the average quantity of coal consumed has declined since 1871 to the extent of 16 cwt per ton of pig-iron made in the United Kingdom. As the annual make of pig is almost 6,000,000 tons, the total economy is about 4,800,000 tons per annum. Another saving occurs in the manufacture of steel rails by the Bessemer process, the quantity of coal required to produce a ton of such rails being generally admitted to be 65 per cent. less than that required for iron rails. The annual production of steel rails is about 650,000 tons, so that we have a reduced consumption of fuel of about 1,166,500 tons as compared with iron rails. There are also other departments of iron-making in which the consumption of solid fuel has been greatly reduced of late years by the use of the waste gases from the furnace, as well as by improved methods of working. This is what we want. Now that consumption has reached such a point in relation to supply, that coal owners are seriously attempting to bring coal to the surface, from a depth, that, fifty years ago, would have been considered madness. Coal as a rule has been such a cheap fuel, that even in this age of Mechanical ingenuity, very little has been done by way of inventing fuel saving appliances. It is, however, high time that something should be done, and judging from past experience, we do not suppose much will be done, till legislation enactment makes the consuming of smoke compulsory.

A VERY remarkable deposit of pretroleum is described by the American Consular Agent at Maracaibo as existing between the Rio Tara and Zulia. Near the former there rises a sand-bank about 35 yards in extent, and some ten yards in height. On its surface is visible a collection of cylindrical holes, apparently artificially made and of different diameters, through which streams of petroleum, mixed with boiling water, gush out with great violence, accompanied with a noise as though two or three steamers were blowing off steam. The column of vapour that ascends from

it would doubtless be seen from a long distance were it not shrouded by the thick forest, to which the petroleum beds that evidently lie underneath give a perpetual greenness and freshness of foliage. A curious phenomenon has been occasionally seen in Venezuela ever since the conquest, consisting of a frequent lightning without any explosion, which is observable from the bar at the entrance of the Lake of Maracaibo, close to the Island of Bajoseco, and which Colonel Codazzi, in his geography, attributes to the vapour ascending from the Cienega de Agua Caliente. This appearance, called by mariners " El farol de Maracaibo," is more probably due to the inflammable gas that permeates the whole district to such an extent that it is known by the natives as El Inferno. The substitution of petroleum of coal as a steam raiser, is now on its trial,and scientific men are not without hope that the liquid form of petroleum, and its more concentrated power, will soon be turned to account in this direction.

PETROLEUM IN VENEZUELA.

A REMARKABLE deposit of petroleum is described by the American Consular Agent at Maracaibo as existing between the Rio Tara and Zulia. Near the former, there rises a sand-bank about 35 yards in extent and some 10 yards in height. On its surface is visible a collection of cylindrical holes, apparently artificially made, and of different diameters, through which streams of petroleum mixed with boiling water, gush out with great violence, accompanied with a noise as though two or three steamers were blowing off steam. The column of vapour that ascends from it would doubtless be seen from a long distance, were it not shrouded by the thick forest to which the petroleum beds that evidently lie underneath give a perpetual greenness and freshness of foliage. Dr. M'Gregor states that from one of these holes, notwithstanding the difficulties of the position, he filled, in 42 seconds, a vessel containing 15 bottles, or as fast as four gallons per minute, or 240 gallons per hour, or 5,760 gallons during the 24 hours. A curious phenomenon has been occasionally seen in Venezuela ever since the conquest, consisting of a frequent lightning, without any explosion, which is observable from the bar at the entrance of the Lake of Maracaibo, close to the island of Bajoseco, and which Colonel Codazzi, in his geography, attributes to the vapour ascending from the Cienega de Agua Caliente. This appearance, called by mariners, " El sarol de Maracaibo," is more probably due to the inflammable gas that permeates the whole district to such an extent that it is known by the natives as El Inferno. There is no doubt that the supply of petroleum is very abundant not only here but in the neighbouring Republic of Columbia, where, between Escuque and Bettijoque, the labourers gather it up in handkerchiefs, which, when saturated, are squeezed out into barrels.—*Times.*

MARBLE QUARRIES OF ALGERIA.

THIRTY-FOUR kilometres north-east of Oran, on the high road to Arzeu and Mostaganem, is the small village of Mefessour ; a branch road to the north-west leads to the still smaller village of Kleber. Above this rises the imposing mountain called Djebel Orousse, generally called " Montagne Grise " from its arid, grey appearance. The chain of hills, the highest point of which is about 2,000 feet above the sea, stretches in a north-easterly direction from Cape Aiguille to Cape Carbon, and includes Cape Ferrat. The central part of the range forms an elevated plateau almost perfectly level, with a superficies of 1,500 or 2,000 acres, it has hardly any soil or vegetation, nothing, in fact, to hide, as Consul Playfair states in his last report, " that it is an uninterrupted mass of marble and breccia, the argest and finest, probably, that the world contains." Consul Playfair gives it as his opinion that, not even in the Mosque of Cordova, which, as regards marble columns, is an epitome of all the finest Roman and Greek temples, is marble of greater beauty or variety to be found, and, as far as quantity is concerned, there is as much as in all France and Italy together, not excepting the mountains of Carrara. The discovery is due to a Signor del Monte, who was also fortunate enough to discover the well-known quarries of alabaster, called " Algerian onyx," at Ain Tekbulet, near Tlemcen. He purchased them from the Arabs for a mere trifle, at a time when the country was still unsubdued, and when no one could approach them without danger to his life. He has now obtained a concession of the " Montagne Grise," for a long period of years, and on very favorable terms. The area is about 1,500 or 2,000 acres only, but he has also obtained all the land round about in which there is any chance of marble being found, amounting, in all, to 14,410 acres, so as to avoid the possibility of competition. The whole of this area is an uninterrupted mass of marble and breccia, which only requires to be detached and carried away; roads have been made in every direction, so that there is no practical difficulty in doing either. All over the surface of the elevated plateau may be seen circular depressions marking the sites of Roman quarries, and these, to a great extent, indicate the position of the different varieties. The soil, where any exists, is of a deep red colour containing small particles of iron ore ; mines of the same mineral exist in some places, and have been worked, but there is not a sufficient quantity of the mineral to make this remunerative. The ore has already served its purpose—a much more important one—by imparting an infinite variety of rich tints to the marble and breccia rocks. Consul Playfair remarks : " I almost fear to say—all I wish on this subject, last I should be charged with exaggeration, but in sober truth, during the two days I spent in examining the ground, in every direction I passed from one marvel to another, and left in amazement at the magnificence of the treasure which has so long lain, I will not say concealed, but exposed to the most superficial gaze there." The marble is found not in isolated spots, or in limited quantities, but in boundless profusion, and capable of yielding monoliths of any size. Although many varieties are found in practically inexhaustible quantities, by far the most common is the " Giallo Antico." Of this, great varieties of tint are found, and Signor del Monte states that some of it is precisely similar to that of which the columns of the Pantheon at Rome are made. The most delicate and beautiful, as well as the most valuable, is a marble of an exquisite rose tint, which is capable of being used either in large masses or in the finest ornamentation. Consul Playfair states that he has seen a breast-pin made of it, which could hardly be distinguished from pink coral, and blocks from which the largest columns might be cut. With this rose-tinted marble is also found a rich creamy white and another variety, pure white ; but it is in the breccias that the greatest variety of form and colour is to be found. they are moreover, perfectly homogenous, the pebbles and the cement which form the mass being of equal hardness, and taking an equally good polish ; there is also another advantage, they leave no holes requiring to be filled up with artificial cement when worked. In the Paris Exhibition of 1878, there was a magnificent trophy of marble work in the centre of the Galerie Rapp, exhibited by Monsieur Cantini, of Marseilles, for which he obtained the gold medal. Almost everything connected with this trophy, Consul Playfair says, was obtained from the quarries of Kleber. From inquiries made, it would appear that the cost of extracting the marble and transporting it to the sea for shipment is not great. The extraction of the blocks costs 50 francs per cubic metre ; the transport to Oran (about 27 miles) costs 40 francs, and to Arzeu (12 miles) 25 francs Royalties amount in addition to about 30 francs per cubic metre. It is estimated that the marble could be laid on the quay at Oran for 120 francs. per cubic metre, or landed in London for less than 200 francs. The only other varieties of marble found in Algeria are the Algerian onyx before mentioned, the breccia of Chennonah, of a very inferior quality, and the white marble of Filfila, and other places, which can never compete with Carrara.—*Society of Arts Journal.*

GOLD MINING AT DEVALAH.

INDIAN GOLD MINES CO.'S WORKS.

THE works of the Indian Gold-Mines Company at Nadghani, Devalah, South-East Wynaad, are making very satisfactory progress, under the superintendence of Mr. H. A. Severn, and the public are free to see for themselves what is going on. The most prominent piece of work, which meets the eye on arrival, is a partially finished, but substantially built, dam. This structure is composed of bastard granite and Portland cement, and is said to be admirably calculated to withstand almost any pressure of water. At its present stage, the dam measures, roughly, 64 feet in breadth across the top, and 30 feet at bed-rock ; 27 feet is the thickness, and 45 feet will be the height when finished. It is 16 feet high, and it is not intended to go any higher this season. The object of the dam is the storage of water, which would otherwise run waste during the monsoon. Thirty or more acres of a natural reservoir is rarely to be met with, and the value of it is considerably enhanced by the fact that the situation commands the entire property, and is at the highest requisite point for drilling tunnels by compressed air. for quartz crushing, for sluicing, and other operations. Leaving the dam and reservoir, a visitor's attention is next directed to the water-race, which is supplied by a 20-inch cast-iron pipe, and a suitable sluice valve through the bottom of the dam. The race skirts a hill for about 400 yards. Following its course is a well-constructed tram-road, which also extends t about 400 yards, and trucks are here and there seen working backwards and forwards, carrying stone from the quarry, and conveying heavy machinery and working gear to their destination. Towards the end of this road can be seen the mechanics' workshop, a well-built and commodious place to work in, measuring 46 feet by 30, containing a 14 foot screw-cutting lathe, a drilling machine up to 3-inch hole, and benches, vices and all requisite modern appliances for carrying out repairs in an efficient manner. The whole of this machinery will be worked by a 15 horse-power turbin, which is situated immediately to the east of, and close to the workshop.

Close to this spot is an incline self-acting tramway, worked by 880 feet of wire rope, connecting the upper tram-road, already referred to, with the main level below. This incline is at an angle of 45 degrees, and is 350 feet in length. It is laid with a single line of rail looped in the centre, for running self-acting trucks. This work is so devised that a loaded truck going down the incline, simultaneously works up an empty one : and while one truck reaches the loading platform at the top of the incline at the identical moment, the other arrives at the turn-table below, for the purpose of unloading. The safety of this method is controlled by an ingenious brak-winch at the top. The incline terminates at the eastern end of the main tunnel level, which is a road-way that will ultimately connect the eastern with the western boundary of the property. At the western end of the upper tram-road descends a 12-inch cast-iron water pipe, 893 feet long, at an angle of 40°. This is termed a water column, and terminates at what is technically known, as a foot-step, on the lower level road. This column is composed of 33 joints, or lengths. The foot step is a T-piece, one branch of which leads to the air boring machinery and the other to a quartz-crushing battery, available for any other purpose that may be necessary, and which is already at hand. Nine pipes lead from the foot of this column to a 25 horse-power turbin, which is

connected to the crank of engine by mortice and spur gearing, thus reducing the speed of the turbin by two motions. The engine compresses air by the wet process into a "receiver," resembling an ordinary Cornish boiler, 18 feet long, and 3 in diameter, to about 152 lbs., pressure per square inch. This air is transmitted from the compressor by suitable pipes and hoses, to the Darlington rock-boring machine, situated in the tunnel, where the strength and capabilities of the reservoir and its water-supply will be brought practically to bear on the prospecting underground. The whole of this machinery stands in a spacious building, 46 by 24 feet, where are also provided an office and changing room: Among other things to be noticed here is a permanent magnetic machine, comprising ten magnets, connected by a double wire cable, by means of which all the blasting in the tunnel will be effected, thus obviating the possibility of accident, and economising time.

The main office, which is close to the engineers' bungalow, is in telephonic communication with the office at the tunnel, and it is intended to extend this line of communication to the "Alpha" works, thus bringing the operations within speaking communication of the engineer's head office. From the main tunnel, a road has been completed, and is about to be railed, to a two-foot gauge, extending to the westward, around the slopes of hills, over gullies, and through rocks to the Alpha slopes, a distance of about 1½ mile, where a crushing mill, manufactured by Appleby Brothers of Greenwich, consisting of twenty stampers driven by a 50 horse-power turbin, will be erected shortly. The crushing mill will be inclosed in a capacious wrought iron building, specially imported. The stampers of the battery are 8½ cwt. each, and will be worked five in a box. The bedbox, or coffer, of each set of five stampers weighs 3 tons. The stampers have a 12-inch drop, and are calculated to produce eighty strokes a minute. Special provision has been made in this mill whereby any five head of stampers can be unpitched at will. The mill, with the exception of the coffers, is entirely constructed of wrought iron and malleable and cast steel. The copper tables are from 16 to 24 feet in length, and the blankets streaks even longer. On the tailings leaving the blanket streak they will be further operated upon by the machine known as the Berdan, of which there are six of 4½ feet diameter. Attached to this large mill is one special stamper, with appurtenances complete, for the purpose of making experimental crushing of stone obtained from any part of the mine. Within this building are suitable offices, retorting room, store-room, and all necessary accommodation. The entire mill has been imported by the Company, to crush the Alpha stone, and it is chiefly with this object that the construction of the road previously alluded to was undertaken in order to facilitate the transport of the necessary machinery to its proper site. In regard to the Alpha property, which is affiliated to the Indian Gold Mines Company, and which already possesses an old-fashioned 15-steamer battery, and a portable engine placed in a most unsuitable spot for water and crushing, Mr. Severn has seized the opportunity to repair both mill and engine, with the object of getting as much work out of the old plant as is possible. The stamps are expected to start within a month. Extensive surveys, levels, prospecting operations, &c., have been carried on here, as well as on the other properties of the Company. Five dwelling houses have already been built, as also a capital office, laboratory, melting house now in course of erection, and numerous sheds, stores, &c. Altogether, there is quite enough to be seen to impress one with the idea that this part of the gold district of Wynaad bids fair to become a small colony of itself. One special feature in the whole of what has been described is, that Mr. Severn appears to have had no difficulty in regard to labor. Considering the magnitude of the work he has undertaken, it is refreshing to hear him admit that all through the work he has been well seconded by the entire staff, including Europeans, mistries, and coolies.—*Madras Mail.*

GOLD MINING IN QUEENSLAND.

IT appears from a report issued by the Department of Mines, Queensland, which has just been presented to Parliament, that the approximate yield of gold in the year 1879 amounted to 288,556 ounces, as compared with 309,612 ounces in 1878. This decrease of 21,056 ounces represents a loss of £73,696, and would seem on a superficial examination to be a very severe falling off in the gold yield of the colony. But a decrease was anticipated, owing to the bed of the Palmer River (the principal deposit of alluvial gold and its auriferous tributaries having been to a great extent repeatedly worked over, and consequently until new auriferous ground is discovered, a falling off must be expected. Although there is this considerable decrease in the quantity of alluvial gold produced, it has not been from the individual earnings of the alluvial miners being less than in the previous year, but from the decrease in the number of that class of miners. There has, in fact, been more gold produced in the Palmer district, relatively to the number of miners working during 1879, than there was during the previous year. This is accounted for by the improved system upon which the Chinese now work, that is, in large gangs sluicing, instead of as formerly in small parties cradling, and by the discovery of several new patches of ground which, although of small extent, and soon worked out, yet yielded large returns.

The quantity of gold exported in 1879 amounted to 281,552 ounces, and it will be seen that there is a difference of 7,004 ounces between the amount exported, and that actually produced. This is due to the fact that a considerable quantity of gold is carried away in small parcels, by persons who do not make entries of it at the Customs. The number of miners at work in the colony in 1879 shows a decrease, as in 1878 there were 2,980 European quartz miners, 654 European alluvial miners, and 1,695 Chinese alluvial miners, in all 14,490; whereas in 1879, there were 2,750 European quartz miners, 441 European alluvial miners, and 5,621 Chinese alluvial miners, in all 8,812. Mr. Lukin, the Under-Secretary of mines, explains that this is but a rough statement, as the wardens of the separate gold-producing districts have not the means of obtaining a very accurate estimate; it is possible to arrive at reasonably correct calculation of the number of settled quartz miners on the older fields, but not of the large floating population of alluvial miners, Chinese, and prospectors, scattered over thousands of square miles of country. The decrease in the number of Chinese, 5,235, is very great; it appears, however, that 889 left one district alone, that of Cookstown, for China, while only 54 have arrived from that country. Numbers have left for southern ports, many have taken to agricultural and other pursuits, a considerable number have dispersed themselves over the many old alluvial fields of the colony, and moving about in parties have no doubt escaped enumeration in the totals returned by the wardens as engaged in mining. Death accounts for a considerable number in the decrease: the death-rate among the Chinese having been abnormally great during the early part of 1879. The falling off in the number of European alluvial miners is accounted or by the exhaustion of the alluvial fields. The decrease in the number of quartz miners has occurred principally on the far northern fields, where many have been disheartened by the difficulties against which they have had to contend, chiefly through the insufficiency of capital necessary to work the ground profitably. The commercial depression, so general throughout the colonies, has debarred the storekeepers, tradespeople, and speculators from backing the working miner as in previous years, when money was plentiful and credit easily obtained. Quartz mining is, however, in a satisfactory condition, as in the principal reefing districts—those of Charters Towers, Gympie, Hodgkinson, Ravenswood, Palmer, and Etheridge, and Gilbert—the yield of gold, in 1879, amounted to 175,668 ounces. This amount, though slightly less than that produced in the two previous years, considerably exceeds that for 1876, when it amounted to 151,587 ounces. The decrease, however, is nothing more than the ordinary fluctuation observable in the returns from all established gold fields during a series of years. Mr. Bligh, the warden of the district of Gympie, partly accounts for it by explaining that, in some divided-paying claims, raising stone has been suspended for a time during the erection of better mining machinery, a change which, though causing an immediate falling off in the production, inevitably leads to a better yield in the future. There is no falling off in the richness of stone at the deeper levels now being worked, and new and promising ground has been opened. Several new reefs, distant about ten miles from the town of Gympie, but within the Gympie Gold Fields, have been tried. A trial crushing from the first one discovered (the Veteran) gave a yield of nearly two ounces to the ton. Equally satisfactory reports come from the other districts. A comparison of the amount of gold won with the number of miners working, shows that the position of the individual miner continues to improve The actual number of men working was—Europeans, 3,191; Chinese, 5,621 making a total of 8.812. As the total yield of gold for the year was 288,556 ounces, which at an average of £3 10s. per ounce, represented £1,009,946, it places the earnings of each individual miner at £114 12s. For the year 1878, it was £74 15s. 8d. Excluding alluvial mining, which is mainly carried on by Chinese, and taking quartz reefing, which is exclusively in the hands of Europeans, it appears that the yield in 1879 was 189,741 ounces total value, £664,094 average earnings of each miner, £250; against 179,083 ounces in 1878, value £626,688; average earning of each miner, £201 9s. 9d.—*Society of Arts Journal.*

THE SEARCH FOR GOLD.

THOSE who assert that Government should initiate the search for gold, forget that so large a portion of the crown lands in the interior has passed into private hands, that it is very doubtful if the Government own any tracts on which quartz reefs exist, and it is not very evident how Government could undertake to search on any other than crown lands. Those who had hoped to have secured the professional services of Mr. Cameron, who recently arrived in the island, have been disappointed, as that gentleman like Mr. Harvey, was unable to remain in the island. No doubt the presence of these experts in London is much needed by the various companies who desire their special reports on their properties, with as little delay as possible.

So far from the Government being likely to take any steps to encourage the search for gold in Ceylon, we understand they have steadfastly set their face against the enterprise, in the mistaken belief that the discovery of the precious metal in any quantity, would unsettle the natives of this country and interfere with the supply of labour. This feeling has had its origin no doubt in what occurred in Australia on the discovery of the gold fields there. But it appears to be forgotten how great a dissimilarity there is in the two cases. In Australia, gold was found near the surface in alluvial soil capable of being worked by hand without the slightest difficulty, and naturally large number of people were attracted to the gold diggings which required so little means for their working. In Ceylon the case is very different, but there is little doubt that whatever gold exists here will be in quartz reefs requiring a great deal of labour in their working, which would place

it out of the reach of the ordinary labouring man, and as in South India requiring the employment of machinery. Anything like a rush therefore, to any particular locality is quite out of the question, and it may be well to bear in mind that the land on which it is probable gold may be found, has passed into the hands of private parties. The sooner therefore the Government disabuse their minds of this fear on account of any gold discovery, the better. There need not be the slightest apprehension of our labour market becoming disturbed by any such influence.—*Ceylon Times.*

DIAMOND DIGGINGS.

THE diamond-field, which now yields the chief supply, is the South African, an interesting account of which was given by Mr. R. W. Murray, a Cape colonist, at a recent meeting of the London Society of Arts. There, as in Brazil, diamonds were being handled by people who had not the remotest idea of their value. The child of a Boer on the banks of the Vaal River was playing with some pretty pebbles which she had picked up, when one of them by its lustre attracted the attention of a passing trader. Having confided to the girl's father his belief that the pebble was a diamond, the trader agreed to have the profit with him should his surmise prove correct. The Queen's jewellers pro- nounced it a diamond of 22½ carats, worth £500, and at this price it was purchased by Sir Philip Wood-house, at that time Governor of Cape Colony. The receipt of half this sum by the parent Boer called to his recollection the fact that he had seen a similar stone in the possession of a native, and seeking him out, he gave him says Mr. Murray, nearly all he possessed—500 sheep, horses, &c.—in, exchange for his pebble.

It proved to be a diamond of 83 carats, and obtained for it £11,200. This is the stone now in the posses sion of the Countess of Dudley, and known as the "Star of South Africa." Such finds" naturally produced the wildest excitement throughout South Africa, and led to a rush of diamond seekers, first from the surrounding colonies, and soon from all parts of the world. The early parties had no idea of digging for diamonds, they sought for them on the surface along the ridges of the hills, and succeeded tolerably well. An Australian gold digger arriving on the scene inaugurated the "cradling" method employed in California and Australia for the separation of the gold in alluvial deposits. The diamond ferous soil, consisting of drift and pebbles of agate, jasper, and cornelian, with here and there a diamond, was dug out and, after thorough washing the gems were readily picked from the gravel. In 1870, within a year after the the first rush, there were 1,000 cradles at work on the banks of the Vaal. These were known as the *wet* or *river* diggings, but after a time they were abandoned for the more productive *dry* diggings. These were too far from the river the to render the washing of the diamondiferous material possible, nor was it needed owing to the light sandy nature of the soil. The digger had only to pass the stuff through a couple of sieves over a sorting table when the sorter was able to pick out whatever diamonds it might contain. The first possessors of those dry "claims" dealt only with the loose upper soil, sinking their pits to a depth of only three or four feet. Their successors, however, finding the surface diggings exhausted, tested the rocky stratum beneath—" a kind of cosely-packed rock, blue in colour, and hard to crumble," which the early diggers had regarded as putting a period to their hopes if diamonds deeper down—when they were rewarded by finding that to contained more and finer diamonds than even the best surface deposits. Diamond mining was accordingly begun, and with it came the need of steam machinery and other expensive plant, necessitating the employment of a large amount of capital and the formation of mining companies. Mines have now been sunk to a depth of nearly 400 feet, in the course of which reefs, not diamond bearing, have had to be cut through, and powerful pumps to be employed to prevent flooding. Those diamond-bearing, areas are circular in shape and form what are known as "pipes." They are filled with intrusive rocks which have been forced up by volcanic agency almost perpendicularly through the surrounding horizontal strata of shale, and through which, as well as through a calcareous tufa usually found on the upperparts of the "pipe," the diamonds are disseminated. Owing to the fact that a larg portion of the diamonds consist of fragments, it is generally thought that the 'pipe' rock is not the true matrix of the diamonds, but it has merely been the agent in bringing them to the surface from some lower deposit.

The richest of the mines is that of Kimberley, which has an area of about seven acres. Its original possessor sold the estate, of which it was but a small part, for £6,000, and it soon yielded to its purchasers from £20,000 to £25,000 per annum in rents. The Kimberley mine contains about 400 claims, which four years ago were worth three-quarters of a million sterling; in August last, according to Mr. Murray, they could not be purchased for three and a-half millions. There is no means of accurately ascertaining the value of the diamond production of South Africa, but the importance of the new industry may be gathered from the fact that the value of the diamonds sent through the Post Office in 1879 amounted to £3 685,000. Since the finding of the "Star of South Africa" much larger diamonds have turned up, notably one found in 1872, weighing 288½ carats, from which it is believed that a brilliant weighing half as much again as the Koh-i-noor may be cut, and the still larger one found by Mr. Rhodes, recently exhibited to the Queen. Unfortunately, the diamonds of South Africa are not all of purest water, the majority of them being straw-tinted, and therefore of considerably less value than colourless specimens.

A trunk railway is about to be constructed to connect the diamond region with Cape Colony, which will have the further effect of developing the other resources of a rich but hitherto inaccessible region. The discovery would seem also to have benefited the natives by finding employment for them at remunerative wages, and by bringing them under civilising influences. Most of the manual labour at the mines is performed by natives, of whom 640,000 have been registered during the past seven years as servants of claimholders. These earn 10s. per week besides their food, and in the great majority of cases the discipline of steady work has, according to Mr. Murray, transformed those (at first) lean, naked and stupid natives, into well dressed, well-fed, and, on the whole, well-behaved workmen, with sufficient intelligence to see to the building of schools and churches for themselves.—*Scotsman.*

FORESTRY.

MR. JAMIESON, Superintendent, Government Botanical Gardens, Ootacamund, has submitted a rough plan for the laying out and planting with ornamental trees and shrubs the waste land on St. Stephen's Church Hill. In selecting the trees named, two objects have been kept in mind—first, only such trees and shrubs have been selected as are likely to thrive in the dry, gravelly, and comparatively poor soil of the hills; secondly, such trees only as differ in character and general appearance from those with which the adjoining hill sides are planted. The selection being comprised chiefly of *Pinus, Cupresses*, and their allies which have a habit of growth peculiar to themselves, will, when grown up, contrast pleasingly with the forest of *Eucalypti* and *Acacia* by which the hills are surrounded. Mr. Jamieson's scheme has been approved by the Government, and is to be carried out without delay at a cost not exceeding Rs. 1,000. He proposed some new paths and roads, but the Government say these are superfluous, and they do not contemplate the employment of any permanent establishment.

THE *Eucalyptus globulus* seems to be doing good service in the Campagna according to recent advices. So virulent was the fover originally, that no less than eighteen of the brothers of the Tre Fontana monastery succumbed to it whilst planting the first *Eucalyptus* trees in that neighbourhood; now, however, upwards of 26,000 of the trees flourish there, and the local malaria has thereby been practically deprived of its malefic influence, and all thoughts of giving up the monastery have effectually passed from the minds of the faternity, who expect, ere long, to be as healthy there as in any other part of the country. Mr. Rimmel should note this fact as a piece of evidence inductively in favour of the hygienic value of his "aromatic ozoniser."

IN Mahren, Germany, where the refuse of the land on the banks of the river is increasing rapidly, the question of planting osiers on the river banks, which has long been talked of, has at last been taken into serious consideration, and the Technical Museum of Industry, before whom the matter was placed, deputed Dr. Broitenlohnen, the head-master of the High School for Agriculture in Vienna, to make an inspection of the river banks, which inspection took place during last autumn. The importance of carrying out the plan of planting osiers was fully recognised, and it is hoped that the steps which are now being taken will, when completed, prove highly beneficial to both the upper and lower classes.

THE cultivation of osier beds and the basket-making industry is beginning to flourish in Rhenish Prussia; Burgermeister Krake, a man who has some authority on the subject, was sent by the Agricultural Society of the Rhine province to inspect the osier beds in France, and declares the French method of cultivating these plants to possess many advantages over the German. The French confine themselves to one particular seed, and rarely venture to cultivate a new sort. The three principal kinds of seed sown are the *Salix amygdalin*, the *Salix viminalis* and the *Salix alba*.

THE WAX PALM IN PERNAMBUCO.

THE Camanba palm *(Copernicia chifera)* seems to be a much more important plant in some parts of Brazil than is generally supposed. In Pernambuco the plant is very abundant, and the uses to which it is put very numerous. The wood, for instance, is used for roofing, both as beams or rafters, and as laths upon which to support the tiles; the fruits are used for feeding cattle, and the leaves are used for making hats and mats. A valuable medicine is obtained from the roots, which has recently been brought to notice in this country. From the shoots or leaves a wax is obtained; for this purpose they are cut before they unfold, dried in the sun, powdered and boiled, the wax rising to the surface of the water. This wax, it is stated, is not produced in anything like the quantity that it might be. It is shown, in a recent report of her Majesty's Consul at Pernambuco, that the export of this wax during 1875-76 amounted to 18,668 kilos., valued at £758; in 1876-77 to 171,980 kilos., valued at £6,957; in 1877-78 it fell to 89,482 kilos., of the value of £3,168; and in 1878-79 to 1,542 kilos., valued at only £61. By far the largest portion of this wax finds its way to this country. It is shown that the decrease during the last year was due to the famine and drought which so severely crippled all industry in the province. It is not a little remarkable that, at a time when roasted date stones are proposed as a substitute for coffee, we should also learn that the stones or seeds of the Camanba palm, when roasted, are used in Pernambuco as coffee.

THE GROANING TREE.

THE history of the groaning tree is this: About forty years ago a cottager who lived near the centre of the village of Badesley, near Lymington, heard frequently a strange noise behind his house like that of a person in extreme agony. Soon after it caught the attention of his wife who was then confined to her bed. She was a timorous woman, and being greatly alarmed, her husband endeavoured to persuade her that the noise she heard was only the bellowing of the stags in the forest. By degrees, however, the neighbours on all sides heard it, and the thing began to me much talked of. It was by this time plainly discovered that the groaning noise proceeded from an elm which grew at the end of the garden. It was a young vigorous tree and to all appearance perfectly sound. In a few weeks the fame of the groaning tree was spread far and wide, and the people from all parts flocked to hear it. Among others it attracted the curiosity of the late Prince and Princess of Wales who resided at the time for the advantage of a sea bath at Pilewell, the seat of Sir James Worsley which stood within a quarter of a mile of the groaning tree.

Though the country people assigned many superstitious causes for this strange phenomenon, the naturalist could assign no physical one that was and in any degree satisfactory. Some thought it was owing to the twisting friction of the roots. Others thought it proceeded from water which had collected in the body of tree or perhaps from pent up air. But no cause that was alleged appeared equal to the effect. In the meantime the tree did not always groan, sometimes disappointing its visitants, yet no cause could be assigned for its temporary cessations either from seasons or weather. If any difference was observed, it was thought to groan least when the weather was wet, and most when it was clear and frosty; but the sound at all times seemed to arise from the root.

Thus the groaning tree continued an object of astonishment during the space of eighteen or twenty months to all the country around; and for the information of distant parts a pamphlet was drawn up containing a particular account of all the circumstances relating to it. At length the owner of it, a gentleman by the name of Forbes making too rash an experiment to discover the cause, bored a hole in its trunk. After this it never groaned. It was then rooted up with a further view to make a discovery, but still nothing appeared which led to any investigation of the cause. It was universally however believed that there was no trick in the affair, but some natural cause really existed though never understood.

MALARIA AND THE VALUE OF THE *EUCALYPTUS*.

THE hygiene of the *Eucalyptus* and pine has been carefully studied by European savants. If there is a healthy spot on earth it is in the heart of the pine forests of Europe. Pine forests are not for us in Southern India, nor is the far farmed *Eucalyptus globulus*, under 5,000 feet elevation, that is to say, just where it begins to be of use in destroying malaria. Most people have read of the wonderful results of *Eucalyptus* planting in Algeria, and in the deadly marshes of Italy and Southern France; but we cannot immediately go and do likewise. *Eucalyptus globulus* is a tree of the temperate zone, and it refuses to acclimatize to a hot climate. It has been grown lower in Ceylon than anywhere else; but for the peninsula of India, 4,500 is the lowest limit at which it is hardy. *Eucalyptus citriodora*—in which the usual aromatic scent of a *Eucalypt* is replaced by a delicious perfume, recalling a combination of scented verbena and lemons,—will grow on a good soil down to an elevation of 3,000 ft., but it is useless for the plains. There are some fine specimens of this tree in Mysore, and it is hoped that it may acclimatise there. Happily the genus *Eucalyptus* is a large one, with species running into the tropics. All the species in a greater or less degree possess the same sanitary and antiseptic properties. Here there is a most interesting study for those who love trees and planting. He who introduces a species of *Eucalyptus*, and proves it hardy in the plain of South India, will deserve to rank not far below those who brought cinchona from the antipodes, or M. Rammel, the enthusiastic Frenchman, who introduced the cultivation of *Eucalyptus* into Europe. Uninterrupted efforts have been made for the last fifteen years to grow *Eucalyptus* in South India. On the plains all these efforts have failed; primarily because the seed obtained was from a species with a temperate habitat growing in the cooler settled portions of Australia. What is required, is that the seed should be from tropical species, and that the experiments should be carried on continuously, in some selected locality. A species cannot be said to be acclimatized till it has borne seed and healthy plants grown from this indigenous seed. The very multiplicity of the species is a difficulty which all who have had experience of *Eucalypt* planting have felt. There may be twenty or thirty species in nurseries, of these, some of different species, look exactly alike, as young plants. There is often doubt as to the correct naming of the seed. Planted out others alter rapidly in appearance. Certain species, such as *E. rostrata*, *E. microcorys*, *E. saligna*, are easily recognizable at all stages, others not. It is simplest, when they are older, and bear flowers, to consult Baron von Meuller's admirable monograph on the *Eucalyptus*, and see then what are the survivors in the struggle.

Many species only germinate to die, some of those from a temperate climate shoot up like hot-house plants, and fall a prey to white ants, grubs, or the first hot season. Some have an amazingly rapid growth over topping even *Casuarina*. Most grow fast, and die fast. At the end of two or three years, there is a scattered remnant, the neat acre of *Eucalyptus*, is a tangled jungle, but twenty or thirty feet overhead a few graceful tree tops are swaying in the breeze, and others are displaying a massive form. Any one of these may be the tree of the future, to sweeten and adorn the pestiferous swamps of our day, and clustering round human habitations to mark civilisation as does the *Eucalyptus* globulus the homesteads of the Boers in Africa.

People may smile and say that India is conservative, and the British Government practical. Government are conservative, happily, latterly, of their trees, and they have ever had a weakness for tree planting. Trees are one of the few æsthetic pleasures in a country where so much jars on the senses; but the leafy crown, or the gorgeous head of blossom, may conceal decay: as we shake with ague, the doctor nods his head, and thinks that there may be too many trees about the house. Let us plant, but plant with knowledge, and let us banish swamps and all uncleanliness from our midst. Let the man, who would be practical, turn to the published accounts of *Eucalyptus* planting, and the effect of these trees in arresting malaria:—

"The plain of the Dombe in France was once as salubrious as the surrounding country. The exaggerated industry of the marshes transformed it into a pestilential region, when it was quite as fatal for foreign populations to live, as it would have been in the swamps of the Senegal. Sanitary measures are tending to restore it to its former condition. It is evident that we cannot reproach the Dombe with the deleterious influence which human intelligence seems to have undertaken to develope. Deprived of the care which rendered it healthy and luxuriant, the Campagna of Rome has become a branch of the Poutine marshes. On the other hand the environs of Rochefort have become healthy; and Bonfarik, one of the most dangerous spots in Algeria, has once become the centre of a flourishing population."

RATE OF GROWTH OF SAL.

ON a recent tour through the forest of Chota Nagpore, the opportunity was taken to measure Sâl trees wherever possible, with a view to ascertaining the average rate of growth. The best countings were obtained in the Singbhoom forest in a portion of the Anandpur Estate, which the Thakur was working for timber to build the new jail at Chaibassa. Careful countings were made on eight stumps with the following results:—

No.	Girth with bark.	Thickness of bark.	Mean diameter, wood only.	Age.	No. of rings per. inch.
		in.	in.	years.	
1	8′ 6″	1·25	29·5	123	8·3
2	6′ 6″	1	26·5	116	8·8
3	6′ 0″	0·75	21	72	6·8
4	6′ 10″	1	23	120	10·5
5	6′ 6″	1	21·5	93	7·8
6	...	...	22	100	9·1
7	6′ 5″	1	22	93	8·5
8	7′ 8″	1	24	115	9·6

giving an average rate of growth of nearly 8·7 rings per inch. The rings on the clean cut section were particularly well marked for Sâl, and the stumps recorded presented no difficulty in counting. Many more stumps were really examined, but the measurements were not recorded where in the least doubtful.

No. 1 gave the following measurements for the different thickness of 10 to 10 rings, counted as the greater radius only. Owing to indistinctness on some radii, the mean radius measurements were not procurable. These measurements show a comparatively uniform growth:—

Yrs.		Yrs.	
10	1 10/16	80	1 13/16
20	1 5/16	90	15/16
30	1 4/16	100	1 2/16
40	1 8/16	110	1 4/16
50	1 12/16	120	1 2/16
60	2 4/16	122	8/16
70	1 6/16		
		Total ...	17½

In the same forest the following measurements of a log 50 feet long; were recorded:—

	Feet.	Inches.		Feet.	Inches.
Girth at ...	0	114	Girth at ...	30	86
	5	101		40	82
	10	88		50	78
	20	86			

This shows a decrease of 23 inches in 45 feet, from 5 feet to 50 feet, or omitting the first ten feet, where the trunk evidently broadened out—10 inches in 40 feet, or ¼ inch decrease per foot of height. Above 55 feet a big knot unfortunately prevented further measurements. To show the size to which timber in the magnificent Saranda Forests can attain, the following measurements of a big tree may be given:—Height, 125 feet; girth, 121 inches, and this was not a very exceptional case. In the adjoining Government Reserve no large fellings were going on, but the following smaller trees were cut and measured:—

At Rongo on the outer Western Range of the Saranda hills :—

	Feet.	Radius.	Rings.	Rings per inch.
On the hill ridge in a dry place, exposed to hot winds (C. 3472) about ...	1,500	2in.	24	12
At the foot of the hill, locality comparatively moist (C. 3473) at about	1,000	2½ „	18	7·2

On the slopes of the Ankua hill overlooking the Koina valley :—

	Feet.	Radius.	Rings.	Rings per inch.
On the summit ...	2,700	2¼ in.	17	7·5

(The age of this is known, for the place was cleared in 1863 for a survey point.)

On the northern aspect slope, good soil, laterite	2,000	3¾in.	29	7 7
On a western aspect, rock laterite, but very little soil over it	1,800	4 „	62	15 5

These three specimens have been kept and marked C. 3478, C. 3479, and C. 3480 of the Dehra Dun collection. On the hill above Kurkutia in the Kolhan forests, a sapling, or rather shoot, was measured (No. C. 3490), giving 1⅛ inch radius to 9 years of growth, or 8 rings per inch of radius.

These measurements seem to show that the rate of growth of Sâl in Saranda may be taken to be 7 to 9 rings per inch of radius for trees growing on good soil in sheltered localities, and 12 to 15 rings for trees growing in more exposed conditions. For good soil, therefore, we may consider 80 to 100 years as the age at which Sâl may be expected to reach 6 feet in circumference, exclusive of bark.

In the Palamow forests, which are all young and chiefly composed of stump shoots from saplings which have been constantly cut over while yet young, before the forests were reserved, a few countings were also made with the following results :—

Forest	Radius.	No. of rings	Rings per inch.
Kumandi Reserve (C. 3434) ...	¾ in.	6	7
Chanpi Forest (C. 3441) ...	3⅛ „	23	7·5
Seemah Reserve, Neturhat (C. 3440) 3,000 feet ...	2 „	20	10
Seemah Reserve,... Henar Valley ... (C. 3444) Shoot 33 feet high ...	2½ „	10	4

These show that, at any rate, at first the growth of shoots is fast if the locality is favourable, and that even at 3,000 feet on the laterite of the Neturhat plateau, the growth is not bad considering the conditions. That large timber can be grown in Palamow is evident from the measurements of old trees on the Jaigir plateau at about 2,500 feet in a sacred grove. These trees showed a height of 100 feet to a girth of 10 to 11 at 1 foot from the ground. In estimating, however, the probable growth of Sâl in Palamow, it would be too much to count on an average of even 7, much less 4 rings per inch, and it will be safer to take the probable age of trees at 6 feet in girth as about 80 years in good, 120 years in moderate, and 150 years in exposed and high localities. In Chota Nagpore the effects of forest, especially in low-lying spots, just below the hills, are very remarkable. In the Seemah Reserve whole areas of young Sâl forest, evidently of promising growth, are often thus destroyed. But in more exposed places, frost is seldom very destructive, and it would seem that, in Palamow at any rate, it is only the low-lying moist places near to high hill ranges, which are much affected.

The counting of annual rings on freshly cut stumps in Chota Nagpore is by on means difficult, but the markings of the annual rings, seem to disappear as the wood cut seasons, or the stump gets older, and it is then difficult to say always what are annual rings, and what are only lines containing fewer or more pores, but not marking annual growth.

J. S. G.

In Indian Forester.

GARDEN.

IN the Report of the Horticultural Garden, Lucknow, for 1879-80, we have the financial results of certain experiments in cultivating fruit. Some few did not succeed, but they possibiy might elsewhere. Those which shewed a profit were the following. The calculation is per acre :—

Peaches ...	49	1	9	163	11	6	114	9	9
Plums ...	17	3	0	56	14	3	39	11	3
Pumeloes ...	16	2	3	89	11	0	73	8	9
Mangoes and Pineapples ...	31	12	0	200	0	0	168	4	0
Cintra Oranges ...	28	1	9	84	5	3	56	3	6
Total ...	142	4	9	594	10	0	452	5	3
Average ...	28	7	4	118	14	10	90	7	6

Here we have then an outlay of Rs. 28-7-4, yielding an annual profit of Rs. 90-7-6, being at the rate of 318 per cent. on outlay.

These profits refer to ordinary native fruits, could we but introduce better varieties, the profits might be even higher.

ON looking over the annual reports of Government gardens in various parts of the country, we are amazed at the very little that is attempted in the way of introducing home fruits. A great source of health and pleasure would be opened up to Europeans especially by the cultivation of home fruits. How vast, for instance, is the difference between the ordinary country pear (*naspati*) and the Jargonnelle pear. The former is in flavour more like a good Swedish turnip, than any possible class of fruit. That the home varieties can be profitably grown has over and over again been proved by private experiments at some of our hill stations, notably Simla and Mussoorie. During the year 1878-79 and 1879-80 the Government Botanical Gardens distributed no fewer than 10,042 fruit trees. This distribution has been going on for years. Yet good fruit is scarce in those regions ; hence we arrive at the conclusion that only a very small portion—if any at all—if this large number consisted of really good varieties.

HARDENING OFF TENDER PLANTS PREPARATORY TO PLANTING THEM OUT.

THIS is a process which should engage the attention of all who have tender plants in an advanced stage. Vegetable marrows and cucumbers for planting on ridges, dahlias, and all other tender flowering plants that are to be planted out next month, should be gradually inured to a lower temperature before being placed in cold frames to undergo the final process of hardening off. When transferred to the cold frame from the growing temperature in which they have hitherto been placed, keep the frame close for a few days thereafter, and if frosty nights prevail, cover the lights with mats to keep up the night temperature to a safe degree. A little shade in the middle of the day in bright weather will be necessary to moderate the temperature for a day or two; after which air may be given for that purpose, taking care not to admit cold frosty wind within the frame. In order to promote growth as rapidly as possible in subjects that are yet too small or backward in growth, let the frames be shut up early in the afternoon with plenty sunlight upon them, and mat up the lights at night to prevent the heat so obtained from escaping by radiation. Gradually admit more air and give a fuller exposure to light as the time advances and the plants become inured to the new conditions in which they are placed. In the earlier stages be careful to water only with water which is at least equal in temperature to that of the frame.

ADIANTUM WILLIAMSI.

THIS is a new form of 'maiden hairs of most distinct type. Its chief peculiarity is in its young fronds being clothed with golden farina. The form is most graceful, the fronds pale, lively green, with undulated margins to the pennæ ; they are also of good stout texture, and therefore well adapted for cutting. Its culture proves to be very easy. It is a greenhouse fern, or, more properly, an intermediate house one, requiring a temperature of 50 degs. to 60 degs. when growing. The soil should be a mixture of loam and peat in nearly equal parts, with sharp river sand in such proportion as will render the mass thoroughly porous.

4. The statement below shows in detail the areas of the principal crop, Irrigated during the last four years :—

	1877.	1878.	1879.	1880.
Sugarcane ...	139,005	147,661	165,661	135,229
Rice ...	69,684	79,257	75,903	135,570
Bajra and Juar ...	81,137	12,079	6,035	48,266
Maize ...	61,577	65,818	17,265	89,274
Other food-grains ...	12,272	19,326	12,535	9,207
Fodder ...	36 030	17,155	5 996	7,924
Fibres ...	103,309	74,532	59,580	63,680
Dyes ...	214,286	228,284	135,195	294,983
Miscellaneous ...	15 283	15,914	26,871	20,913
TOTAL ...	781,583	660,026	555,641	700,189

The decrease in sugar-cane has taken place in all the divisions of the Ganges Canal, on the Eastern Jumna and Agra Canals, and is due, as just stated, partly to the state of the market, but still more to the failure of the seed.

The area of rice is nearly twice as great as the average area of the three previous years. This is due, as explained before, to the nature of the

season, but a very marked increase on the Rohilkhund Canals, from an area which had not before exceeded 28,500. (This was the area in *kharif*, 1868, the famine year. Acres to 45,511 acres requires special notice nearly the whole of the area of 1880 was under late rice, and the large increase was due to the almost complete failure of the rains during August and the first half of September in the plains, while frequent small floods from the hills kept up the supply in the rivers without serious damage to the head works of the various canals.

THE CAMELLIA.

NEARLY a hundred and fifty years ago this the noblest of all greenhouse shrubs, was introduced to cultivation in this country from Japan. As first introduced, it was only the single red-flowered form, which is now rarely if ever seen in private gardens, but even in that form it was greatly prized for its noble evergreen foliage and its large lustrous flowers, which surpassed in brilliancy and size anything previously in cultivation. A few years later was introduced some of the older double and semi-double kinds yet to be met with in cultivation. But a tendency inherent in the species to sport and vary soon furnished gardeners with the means of largely increasing the number of varities, till at the present time their name is legion. The great simplicity of its culture, combined with its great hardiness of its constitution, its free flowering charactor and great beauty, render it one of the most popular plants with amateur and professional gardeners alike. Flowering also in the dull months of winter, when little besides in the shape of flowers can be obtained without resorting to the costly process of forcing, enchances its value in all respects.

The culture of the camellia consists of a very few details. The time of starting the plants into growth is naturally at the end of the flowering season, which is under ordinary greenhouse culture about the end of March. They may, however, be brought into flower in September, and kept in continuous succession on till May, if there are sufficient plants and the requisite facilities wherewith to treat them as necessary to attain so prolonged a period of blooming. The attainment of this does not, however, in any way affect, the practical details of their treatment beyond the mere period of starting them to grow. If they are wanted to be in flower early, they must be started into growth correspondingly early ; they will not like many plants with which we have to do, force with impunity after the flower-buds are set. The certain result of attempting to push the opening of the flowers at any time while the plants are in a state of complete rest, would be the loss of all or at least the greater part of the flower-buds. The camellia must have complete rest after the flower-buds are set, and any attempt to deprive it of this rest will damage the crop, of flowers both in quantity and quality, and injure the constitution of the plants.

When the flowering period is over the plants will, even when they are kept quite cool and by every means discouraged from making growth, naturally start to grow. By keeping them cool at this stage their flowering period the following season may be thrown back somewhat, and by continuing so to treat them annually, they may be thrown as late as it is possible to keep the plant from making its growth in the conditions natural to our climate. In accelerating the commencement of the flowering period, there is less difficulty than in retarding it beyond certain limits. The plants must, as before stated, be started into growth earlier than their natural period, and; if need be, this must be attained by sacrificing the crop for at least one season. There is rarely any risk of this loss occurring after the first year, for the plant naturally begins to become active at the same time that it was started the previous season, and in this way plants may be, as it were, educated in a few years to bloom from the beginning of September as readily as from the beginning of January. A suitable temperature to start the camellia into growth is by 55 degs. night and 65 degs. day. The night temperature should not, from artificial heat be allowed to exceed the figure stated, although, if the starting period is so late that the outer air may be about that point or near it, no harm will result from raising the thermometer at night a few degrees. The day temperature may be allowed to rise 5 degs. or 10 degs. higher than the figure named by means of sun heat; but a higher artificial heat is undesirable. Abundance of water during the course of growth is of the utmost consequence to the full development of large, handsome foliage, and eventually also of large, splendid flower-buds. During the early stages of growth they must also be freely syringed every morning, and in the afternoon of bright drying days also. The atmosphere of the house in which they are grown should be kept thoroughly saturated with vapor from the evaporating troughs and from sprinkling every inch of dry wall, path, or other evaporating surface in the house. If not duly supplied with moisture at both root and top during the growing time, the plants will not long sustain health, they will become bark-bound, thin, and pale of foliage ; and if subjected to such maltreatment for long, they will eventually die. Provided the drainage of the pot is good, it would be hardly possible to overdo the watering of the camellia while it is making its growth. Liquid manure and soot water are highly beneficial during the growing period, and if applied weak and clear, may be given at every watering.

The compost best adapted to sustain robust health in the camellia is rich, fibrous loam, of a sandy texture. If strong and tenacious naturally, it should be rendered friable and open by the addition of sand and charcoal. In potting, great care should be bestowed upon the drainage, and ever afterwards it should be carefully examined annually, and rectified if wrong.

When the growth is finished, and the process of setting the buds is advancing, the plants are usually set out of doors in a shady position, that behind a hedge with a north or north-west aspect being best. Here they will gradually complete the setting of their buds and may remain till September.

During the growing period, up till the time that the wood begins to become brown and hard at the base, and the foliage has attained to its full proportions, the plants must have plenty of shade, along with a free admission of air when the weather is mild enough to favour its being admitted, anything approaching to dry, scorching, drafts or frosty air, being the only conditions to be avoided or guarded against.

The following selection represents some of the best in the various types of double and semi-double flowers :—Camellias with double white flowers—Alba pliuo, fimbriata—the latter the most elegant of all the whites. Blush-flowered—Lady Hume's Blush. White-flowered, flaked or striped with red—Lavinia Maggi, Bonomiana, Jubilee, Pale pink-flowered—Mons. d'Offoy. Deep pink—Augustina superba, Marchioness of Exeter, Chandlers elegans. Pink or rose flaked with white—Leopold's Benucci, L'Avenir. Deep red and crimson—Imbricata. Often spotted with white on rich scarlet—Mathottiana, a magnificent variety.—*N. B. Agriculturist.*

TEA.

IT is early in the day yet to hazard a positive opinion as to whether or not this season's Darjeeling tea crop will come up to the brokers estimate, but it must be borne in mind that the season has not been an early one, that the weather, so far, has been against quantity, and that throughout the district the general plan this season is to pluck fine leaf only, so far as this can be done consistently with the well-being of the bushes. All these reasons put together seem to go in favor of the outturn being below the estimates formed a couple of months ago. It is very probable that revised estimates will be made by the end of June.

WE take the following from Messrs. Carritt and Co's report of 16th May :—" The first sales of new season's tea were held on the 12th instant, when 2,834 packages were offered, 2,625 of which changed hands. A considerable quantity of half chests and small boxes were included among these, so that the actual quantity sold was equal to about 2,000 chests only. The quality of some of the invoices from Darjeeling and the Dooars was fine but the few parcels from Cachar were of very indifferent quality. There was a good inquiry for all teas with point in cup, but the thin liquoring lower grades, especially Cachars, attracted little attention and were difficult of sale. As compared with last year's opening rates, we quote good and fine teas 2*d.* to, 4*d.* higher, while teas costing under about 1s. 5*d.* excepting a few flavory Darjeelings, were generally 1½*d.* to 2*d.* lower. Teas costing 11*d.* and under, sold at about last year's opening rates.

FINE and finest continue scarce and are readily taken at fully recent quotations. Medium teas are not so quite freely offered, and values are unchanged. Common kinds as usual have formed the bulk of the catalogues, the quantity of broken leaf being so much greater than that of the whole leaf has reduced the values of the former to a very low point ; some light-coloured low Fannings have sold as low as 5½*d.*

As an illustration of how tea has been doing in the past year, we may instance the Muttuck Tea Co., Ld.,—whose outturn was 80,994lbs. The total expenditure was Rs. 51,775-15-5, and the income Rs. 35,728-4-3, shewing a loss on the year's working of Rs. 16,047-11-2. The tea therefore cost per lbs. 10·228 annas, while the average price realised was 7·058 annas, the loss on each lb. being 3·17 annas, rather a discreditable state of affairs we should say.

INDIAN tea statistic brought up to the end of March, are as follows :—

	Imports. lbs.	*Deliveries.* lbs.	*Stocks.* lbs.
1875-76	22,906,000	19,227,400	10,152,900
1876-77	25,632,700	19,503,900	12,105,400
1877-78	32,923,700	24,606,500	17,319,200
1878-79	31,804,400	28,063,300	15,328,300
1879-80	36,875,700	26,620,900	21,381,800
1880-81	42,703,800	34,742,800	23,476,600

This is calculated from 1st of July, which date is in London assumed to be the commencement of the season. During these years the percentage of deliveries and stocks to current year's imports were as follows:—

	Deliveries.	Stock.
1875-76	84	44
1876-77	76	47
1877-78	75	52
1878-79	88	49
1879-80	72	58
1880-81	81	55

From this it will be seen that there is still ample room for improvement in the matter of stocks which are still too high.

THE new market opened in Australia will doubtless help to reduce stocks, by diverting a considerable amount of the total production from the London market, and if the present compara-

tively safe condition of the Khyber Pass continues, we may hope to see from two to three millions of lbs. leaving India for the Trans-Himalayan markets. But perhaps the most hopeful signs in this direction are the steadily increasing home consumption and the very diminished ratio of extensions which has been the rate during the last few years.

As usual we find the London market willing to pay for really good teas. From Messrs. Lloyd and Cheshire's report we take the following :—

We quote the following satisfactory paragraph from the *Australian Trade Review*, dated 9th April last : "Indian Tea—The sale of 19th March was a most important one, the quantity sold being over 3,000 packages, the bidding brisk with full values maintained. This *aftthere distribution of previous shipments among the consumers*, seems to indicate that the introduction of these teas is a success so we may now look forward to far larger shipments during next season."

"From some remarks quoted by Sir Bartle Frere in a paper recently read before the Society of Arts, it appears that a few small plantations are under tea cultivation in Victoria County, and other districts of Natal, and with fair success. A resident at the Isipongo states that with one exception he had bought no tea for six years, but used that grown by himself for his household, and found its flavour very good. The shrub is also said to do equally well in many localities in the Natal uplands." In introducing tea-growing into other countries, the question to be considered is not "will it grow" as we know the tea plant will grow almost anywhere, but "will it yield sufficiently to pay." This is the crucial test. We have ventured to doubt the success of the present attempt to introduce it into America, because of the rainfall being deficient. On this important point as regards Natal, we have no information.

A correspondent writing from Genoa to the *Home and Colonial Mail* relative to the prospect of Indian tea in Italy says :—" At present the consumption of tea in Italy is almost exclusively restricted to the higher classes of society owing to the heavy duty it is saddled with, namely, 3fr. 50c. per kilo (2 lbs.) This duty is moreover quite out of proportion as compared with that on coffee, which is only 1fr. per kilo, and there is no doubt, if the duty on tea were reduced to a reasonable figure and the trade placed on a proper footing, that the consumption would soon attain its natural limits. The revenue it brings to Government now is a mere trifle, and we feel sure a reduction of the duty to one-half its present figure would not only increase the revenue considerably, but also do away with smuggling, which is carried on extensively here in almost every article which, like tea, is heavily taxed with duties." The kilogramme being equal to 2¼lbs. it follows that this duty is equivalent to 1, 3½*d.* per lb. which is almost prohibitive. The duty in coffee is only 4½*d.* per lb. and we trust the Italian Government will soon see their way to make a reduction. The duty on tea is exactly 3½ times heavier than that on coffee. The English duty while much lighter than this is still relatively heavier on tea than on coffee. On the latter it is 1½*d.* per lb. while on tea it is exactly four times that amount.

There are frequent complaints from "The Lane" as to the quality of the China tea sent over to this country. There is a marked deterioration even as compared with the inferior quality of some of last season's shipments. China tea of a kind has been sold as low as 2¾*d.* per lb., a price which we venture to think is sufficiently indicative of the kind of rubbish which now finds its way into the market. India tea, although prices are not encouraging to growers, is becoming more and more popular among consumers. Grocers are directing attention to it, and now it is the rule to see trade announcements in regard to blends of Indian and China, while not a few retailers sell pure Indian tea and think that the exigencies of the times demand that they should announce the fact in large type.

THE ADULTERATION OF TEA.

A FEW months ago we gave the results of a series of analyses of milk sold in Melbourne, made at the laboratory attached to the Industrial and Technological Museum by Mr. Frederic Dunn, under the supervision of Mr. J. Cosmo Newbery. From the same source we have now obtained some particulars of the analyses of many specimens of tea purchased in Melbourne. Great reliance is naturally and deservedly placed by the public on the reports on various articles of food occasionally emanating from this laboratory. Such reports usually refer to analyses spontaneously undertaken, and the particular sources whence the articles experimented upon are obtained are not divulged. Consequently, they cannot be considered as advertisements either of the merits or defects of any individual product. Moreover, they are not usually paid for by any private person. The laboratory, too, is a branch of the public service, and the gentlemen employed therein are not directly under the control of any Minister of the Crown. Very much work has been done at this laboratory in the direction of exposing food adulterations ; and if this work has not resulted in as great a diminution of the sophistication of the articles we habitually eat and drink as could be wished, it is not the fault of the scientists who make the analyses, but of public authorities who neglect to utilise or pay due heed to the information contained in their reports. With regard to the experiments on teas now under consideration, there is much of a disquieting character in the information supplied by Mr. Dunn, as it shows that a large proportion of the tea that goes into consumption in Melbourne is shamefully debased. But it also shows that the white and yellow rogues who derive a profit from the systematic corruption of this article of food could under a proper law efficiently administer, be punished or, at all events, checkmated. In England, grocers are frequently fined for selling adulterated tea ; but here adulterations of all descriptions are allowed to go unpunished.

However opinions may vary as to the effects of tea on the animal economy, there can be no doubt that injury is done to health by using adulterated tea. At any rate if any persons do entertain doubts on that point, they had better refer to recent proceedings in the Medical Society of Victoria when the subject of tea-drinking was before that body. Nor is it necessary to describe the process by which analyses detect the sophistication of tea. The various methods of adulteration of tea may be defined as the addition of "leaves other than those of tea, except those used for scenting ; exhausted tea leaves and damaged tea ; an undue proportion of stalks or vegetable matter foreign to tea of any kind whatever; foreign mineral matter, especially sand, quartz, soapstone, China clay, magnetic oxide of iron, &c. Lastly the substances used for artificially colouring or painting the teas, as ferrocyanide of iron or Prussian blue, indigo, turmeric, &c."

Probably most of the sophistication to which tea consumed here is subjected, is done in China. In that direction the Celestials have acquired a degree of skill far and away beyond that to which Europeans have attained. In Melbourne, very many families buy their teas from Chinese hawkers, whose ways are "quite too winning," the lollies which Chinky Chinky Chopsticks gives to the young ones at the door being a very successful bait to induce the housewife to deal with him. Their teas are highly scented with a good "grip" on the palate ; in fact they are such teas as the Canton short-leaf mixtures, which will be referred to further on. The use of such teas is gradually depraving the public taste. Housekeepers request their grocer to supply them with a similar article, and he asks the wholesale merchant to enable him to meet the demand, and thus the evil increases.

The quality of tea is judged, not only by its aroma and by the flavour and colour of the infusion, but by the amount of soluble matter or "extract" as it is called which it yields. But generally speaking, tea is classified according to the proportion of extract, mineral ash, solouble salts and theine obtained. This rule, however is subject to modification, inasmuch as chemical analysis sometimes reveals that the leaves have been mixed with some foreign matter, evidently added to give extract. Genuine tea contains between 4 and 6 per cent. of mineral matter, 3 per cent. of which consists of soluble salts, and yields in its ordinary air-dried condition extract ranging from 32 to over 50 per cent. As a rule, the younger and better the tea, the higher the percentage of extract. The following able gives an analysis of genuine teas :—

Name.		Locality.	Percentage of Mineral Ash.	Percentage of Extract.	Percentage of Soluble Salts.	Percentage of Theine.	Number of Samples Averaged for the Analysis.
Pekoe	...	China	5·90	38·40	3·75	*	1
Pekoe	...	Ceylon	4·71	45·69	3·16	1·81	26
Pekoe	...	Indian	5·19	41·41	3·19	1·77	2
Do. Souchong	...	China	6·00	36·40	4·14	*	1
Do. Souchong	...	Ceylon	4·78	45·11	3·06	1·81	18
Do. Souchong	...	Indian	5·42	39·66	3·19	2·05	7
Souchong	...	China	5·80	40·80	4·21	*	1
Souchong	...	Ceylon	4·72	43·68	3·10	1·79	13
Souchong	...	Indian	5·26	38·85	3·04	1·62	3

* Not determined.

With regard to this table it would not be fair to use it for the purpose of making a comparison between different tea-growing countries, inasmuch as the Ceylon teas were Exhibition teas, while the Indian and Chinese were obtained from bulk samples which had been sold in Melbourne.

The next table gives the results of an analysis of Chinese teas obtained from the importers, and taken from bulk samples:—

Name.		Price per lb. in bond.		Percentage of Mineral Ash.	Percentage of Extract.	Percentage of Soluble Salts.
		s.	d.			
Congou	...	1	0	5·26	27·52	2·90
Congou	...	2	3	5·74	32·24	2·83
Congou	...	1	0	5·40	33·00	3·56
Congou	...	0	10	5·72	25·86	2·66
Congou	...	0	10	5·80	24·20	2·09
Congou	...	1	5½	5·50	22·84	2·13
Congou	...	1	5½	5·84	21·04	2·64
Congou	...	1	4	5·49	26·66	2·74
Congou	...	1	5	5·90	25·64	3·23
Congou	...	1	3	7·70	29·04	4·77

Congou	...	1	9	5·74	31·04	3·34
Scented Orange Pekoe		1	9	6·10	34·64	3·27

There are very few teas in this lot that would pass the standard for a low class genuine tea, and this, too, notwithstanding the high price paid for a number of them. The majority of the samples must be classed as made-up teas, and consisted principally of exhausted tea-leaves re-fired, tea dust, and withered leaves. In many of the samples an excess of stalks and foreign leaves were detected. In some, especially those mentioned in the table as being sold at 10*d*. to 1*s*. per lb. in bond, chemical analysis distinctly showed that besides the adulterants already named, the leaves had been mixed with some foreign matter evidently added to give extract and colour. One or two samples had been very strongly faced, or artificially coloured with plumbago. Starch paste was likewise found. Had it not been for these foreign matters, which are soluble in water, the percentage of extract would have been much lower. As it was; it will be seen that in the great majority of cases the percentage of extract was below the minimum for the lowest-classed genuine teas.

With regard to Canton short-leaf, it may be mentioned, in the first place, that Canton is the centre of tea adulteration. An analysis of a sample of this description of tea showed that, in 100 parts, it contained:—

Percentage of stalks	28·71
Percentage of green tea	15·74
Percentage of black tea	55·55
	100·00

Many stalks were found foreign to the tea plant, and were ascertained to be cut-grass stems. The percentage mentioned as black tea was, in reality, a green tea which had been faced, probably with plumbago. Foreign and withered leaves were also detected, as were likewise a large number of small nodular particles, which proved, on analysis, to be tea-sweepings or lie tea held together by starch paste. An analysis of the whole sample of Canton short-leaf gave the following results:—

Percentage of mineral ash	6·70
Percentage of extract	37·69
Percentage of soluble salts	3·17
Percentage of theine	0·72

This percentage of theine, which is one of the chief constituent parts of tea, is very low. At the same laboratory, about 70 samples of Foochow congou yielded 1·67 per cent. of theine, the lowest percentage being 1·50. In 71 samples of Ceylon (exhibition) teas, the average percentage was 1·89, and the lowest 1·82; and in about 60 samples of Indian tea, the average percentage was 1·77, and the lowest 1·41. It may be added, with regard to Canton short leaf, that it has a very large sale, and is used by grocers to give the pronounced flavour which is so appreciated by the public. Jasminum sambac, evidently used for scenting purposes, was likewise detected in the sample.

As a rule, Indian and Ceylon green teas, which have been analysed at the laboratory, have proved to be perfectly free from adulteration, and the opposite may be said with a few exceptions of Chinese green teas. Some 60 samples of Chinese black teas, obtained from the most respectable grocers in Melbourne and suburbs, and sold at a retail price of 2*s*. to 2*s*. 6*d*. per lb., were a short time since analysed. The following is a summary of the analysis:—

Name.	Price per lb.	Percentage of Mineral Ash.	Percentage of Extract.	Percentage of Soluble Salts.	Remarks.
	s. d.				
Congou ...	2 6	5·40	35·20	3·50	Highest percentage obtained from 30 samples.
Congou ...	2 6	5·47	26·78	2·56	Lowest do.
Congou ...	2 6	5·63	31·92	3·26	Average of 30 different analyses.
Congou ...	2 0	5·52	34·80	3·13	Highest percentage obtained from 28 samples.
Cangou ...	2 0	5·60	19·57	2·40	Lowest do.
Congou ...	2 0	5·55	30·08	3·06	Average of 28 different analyses.

We will conclude with a few general remarks. The sales by public auction of China teas for the six months ending 31st December 1880, is stated to have been 3,391,000lb. Of this 2,005,000lbs were sold at and under 1*s*. per lb. in bond. The remaining 1,386,000lb. were sold at 1*s*. 0½*d*. to 1*s*. 10*d*. per lb. in bond. The duty on tea is 3*d*. per lb. There can be no doubt that grocers make a great profit out of tea. So no articles they sell at a very low price to get custom but they make up for that on tea. Pure tea will go much further than the ordinary teas, and consequently less need be used. It is well to bear that in mind, because when pure tea is used, too much may be put into the pot, and its very goodness may create a prejudice against it. Many persons condemn a large leaf tea as being of little strength. Such an opinion is erroneous. Some of these teas have been proved by Mr Dunn to be very rich in extract, soluble salts, and theine.—*Melbourne Argus.*

COFFEE.

THE Government Java coffee crop for 1881 is estimated at 813,300 piculs.

COFFEE IN AUSTRALIA.

WE could not perhaps do better than produce a few extracts from an article which appeared in a former issue of the *Standard* on this subject:—"Millicent, the property of Mr. Costello, is situated at about twelve miles distance from town. At the back of a compact homestead the cultivation begins, and here are found 25 acres of coffee, two or three years old, in vigorous growth. It is growing on a spur running north from the mountain. Half the coffee is on the east side, the other on the west side of this spur. The land is the usual basaltic scrub, and we noticed that if possible the coffee looked more flourishing where the stones were most plentiful. William Sabonadiere in his well-known work, "The Coffee Planter of Ceylon," sums up the characteristics of the soil most suitable for coffee culture as follows:—"A dark chocolate colored soil mixed with small stones under ledges of rock and bestrewn with boulders of granite." On Mr. Costello's selection these characteristics are found to perfection. The three-year-old trees have a fair crop of young coffee on them, and the two-year-old trees have already a very promising maiden crop. The trees are planted 6 by 8 feet apart, and the older ones are already topped to four feet in height. Although the entire crop is in a most flourishing condition, those situated on the west the range are in a more vigorous condition than those on the east, being more sheltered from the force of the S. E. gales that the district is occasionally liable to. From the summit of the hill among the coffee one of those magnificent views for which the north side is so justly celebrated spreads out before us. To the east, like a panorama, the waters of the South Pacific glistening in the sunshine, and dotted with innumerable islands of verdant green to the west and south, the dense masses of the coast range and scrub land slopes of Blackfellow Mountain tower high above us. We visited Mr. Costello's coffee nursery where we found many hundred of healthy young coffee plants ready for planting out when the proper season arrives. Highly gratified with our visit, we started on our return after congratulating Mr. Costello upon the pluck displayed by him in his endeavour to introduce a new industry into the district. While on this subject we desire to draw the attention of farmers to the advisability of following Mr. Costello's example. The growth of coffee at Mackay is no longer experimental. The machinery required is inexpensive. The families of many of our farmers could do most of the crop gathering and the demand for coffee in the colonies will absorb all that can be produced for many years to come; while the duty of 4d. per lb. on imported coffee will offer that amount of protection to our producers until the Queensland market is supplied with Queensland grown coffee. That Mr. Costello may be considered the pioneer of coffee growing in Mackay does not admit of a doubt, and we trust he may reap the reward which he so justly deserves for his enterprise."—*Mackay Standard.*

CACAO.

CACAO.

I HAVE heard of such wonderful estimates of the profits of cacao cultivation, framed by those who are just beginning in the low-lands of the Western Province, that I think a slight sketch of my own three years' experience may be of service to them. I may introduce myself as a planter of over forty years standing, with a wide and varied experience but when I began cacao I knew no more of the habits of the plant than I had casually picked up from newspapers, and other publications, to which I had given no particular study: I had, therefore, almost a clean sheet to take my notes on. It is just three years since I sowed my first seed in bamboo cylinders filled with the best soil I could command. Most of them grew, and they were planted out on land that had been trenched, rooted and prepared for Liberian coffee, nurseries with the larger trees left as shade. Here they grew till the best plants were four feet high and were getting their branches, when a belt that separated them from the clearing was cut down, and within a few days not a leaf remained on any of them. Some of them still live, and struggle to send out shoots from the stem, but the wind always defeats their efforts. The next batch of plants were put out, alternately with Liberian coffee on land with a very easy incline to the west, the soil being a loose gravel with much organic matter. This lot got on tolerably till the south-west monsoon opened, when they went the way of their elders. Those that remain alive are making a strong effort, but will no doubt be finished off by the wind when it comes round to the S. W. Of course I have given up all attempts to establish a cacao field on that land. On this place, I introduced 500 well-grown plants, in bamboos, in July 1879, and before the end of that year not one in ten was left alive. They encountered three months of dry weather; they were cut by lizards and crickets; insects riddled the leaves, white ants cut the taproots, just below the surface; the wind stripped them; and now at the end of 21 months I have not 25 of the 500 odd remaining. In November 1879 I sowed the whole field at stake and surrounded each plant with a basket work of cylinder from 15 to 18 inches high. On the portion of the clearing that faces the S.-W., the whole of them died out within four months, and three-fourths of those on the eastern side followed. At the end of May, last year, I put down seed at all the failures, but dry weather set in immediately afterwards and they never even germinated. Finally I put down nearly 10,000 seeds in baskets in September and October, one-fourth of which were cut by lizards and crickets, almost as soon as they came up, and above 1,000 were cut the very first night after planting in the field. At the end of November last year the whole clearing was fully planted. Now in April, one-half of the spaces are vacancies. The number of plants for the place is about 8,000. I have first and last used 25,000 seeds, and I have still upwards of 4,000 vacancies. My conclusion is, that, of all the plants I ever have had to deal with, the cacao is the most delicate, and has in this climate the most enemies. I by no means say that the evils to be encountered in getting up a field of cacao in this climate are insurmountable, for I have one field of ten acres, in which I have not at the end of five months absolutely lost ten per cent. of my plants I do not know whether cacao will when more advanced, be able to resist the prevailing wind, on situations exposed to it, but, so far as my experience goes, it inclines me to the negative side of the question. In every situation that I have had to deal with, the young plant needs temporary shelter, but, so far as I have been enabled to observe, it is not benefited by overhead shade, except when very young. Certainly I have seen benefit from placing a jungle branch with the leaves on, over the basket shield in hot weather. This plant does not take kindly to a soil where sand or gravel are the prevailing ingredients; an alluvial flat, or a deep clayey loam, seems to suit it best.

White ants, I had always believed, touched no leaving plant, and it was only after obtaining the clearest evidence I admitted that the young cacao plant was an exception to the rule: It is over true a tale that they have destroyed tens of thousands in the low country, and will destroy hundreds of thousands more before all the projected plantations are complete. I do not know whether the gentleman who recommended steeped aloe leaves was in earnest. The aloe is by no means a common plant in Ceylon, and is a very slow grower, and nothing can be clearer than the utter impracticability of the plan where there is not an aloe plant within ten miles, or a drop of water to be found on the surface of 100 acres. As to the other enemies of this plant, the lizards and crickets breed most freely in a loose dry soil and do not much affect clays, gravels, heavy loams, &c. There is no doubt that allowing the weeds to take and keep possession of the soil would moderate the ravages of both crickets and lizards on the

cultivated plants by affording them a wider field of choice, but it is an unsettled question, whether the gain in one direction might not be balanced by a loss in another; so far as coffee is concerned, there is no question about the action of weeds. For myself, as the father of monthly hand-weeding on coffee estates, I will not be the man to make the experiment of burying young cacao plants in dirt, in the hope of benefiting them thereby. Seed must now come rapidly down in price, with so many trees coming into bearing at so many points of the country, and there will be little difficulty in maintaining nurseries at a moderate cost, to supply vacancies as they occur.

As to the minor insect enemies, I have observed about half-a-dozen species of caterpillar feed on the leaves, and several species of minute beetles; then a small species of black ant bring the spawn of the white bug and establish it on the tender shoots of a thriving plant, but it generally succeeds in dismissing its unwelcome guest in a few days. Besides all those reptiles and insect foes, there is a large percentage of failure, for which I am still unable to account; a plant of eight or ten inches suddenly ceases to grow, and sometimes remains for months not dead, but sickly, and then suddenly dies off. On examination, there is no sign of insect action, either on root or stem. If this is an effect of dry weather, then why are other less advanced plants not affected in the same way; I have had an ample opportunity this season of studying the effects of drought on the young coffee plants: all that were planted in the same kind of soil, and had grown equally, showed the same day the same signal of distress on the same day, but cacao shows no such uniformity of constitution; a plant that has been cut when very small will fight to establish a fresh stem, through the whole dry season, and probably with success; while its next neighbour, that has met with no check, has been growing freely till it is above a foot high suddenly drops its leaves; sometimes renewing its growth when rains falls, but more frequently going off altogether, even after the advent of rain. I would be glad to learn whether this is common in the experience of other cacao planters, or if it is a special dispensation, affecting the soil and climate which I have to deal with only. The largest plant I have found the white ants dispose of was three feet high, but I have had cases of sudden death, of plants quite as advanced, for which there was no apparent cause. One plant that some time ago I remarked as a specially thriving one I found this morning with all its leaves withered. Finding it was quite dead, I tried to put it up for further investigation, but it retained too firm a hold of the ground for my strength. In February every plant drooped on the 21st dry day, except the very smallest; in March it was the 25th day on which they began to complain. If therefore what I have stated of the cacao be the effect of drought, it would appear that every cacao plant has its own constitution, and that while one gives up in a week another of the same age and treated precisely the same holds out three or four weeks and rapidly responds to the first shower. Mr. Fraser tells us that in Trinidad it is only the larger seeds in the middle of the pod that are used for reproduction. There may be something in that, but we who have been paying a cent. each for our seeds naturally grudge doubling the cost by rejecting any.—*Ceylon Observer.*

COCA (ERYTHROXYLON COCA).

In Mr. Markham's "Peruvian Barks," recently published, he has given the results of his own observations, and collated that of other travellers, respecting this substance, and to this account we are chiefly indebted for the following facts:—

"Coca" the beloved narcotic of the Peruvian Indian, was first named, botanically through the labours of Joseph de Jussieu. The history of this noted botanist is a melancholy one. He left France in 1785, in the ever memorable expedition of La Condamine, and after M. La Condamine left South America, M. Jussieu continued his botanical researches, making numerous journeys on foot, notably those to the cinchona regions. The results of fifteen years labours were contained in certain cases of dried plants, &c., and a native servant at Buenos Ayres, thinking these cases contained money, stole them, and this loss had such an effect on poor Jussieu that he returned to France in 1771 deprived of reason.

The coca is the great source of comfort and enjoyment to the Peruvian Indian. It is to him what the kava-kava is to the South Sea Islander, the betel to the Hindu and Malay, and tobacco to the rest of mankind, but with this difference it produces invigorating effects. The Peruvian Indian looks upon coca with veneration In the palmy days of the Uncas or Yncas, coca was sacrificed to the sun, the high priest or Huillac Umu chewed it during the ceremony, and before the arrival of the Spaniards, coca was used in lieu of money. After the Spanish Conquest, much was done to prescribe its use, because as a Council of Bishops held in 1569, said it was a "useless and pernicious leaf, and on account of the belief stated to be entertained by the Indians, that the habit of chewing coca gave them strength, which is an illusion of the devil." Coca, indeed, form its popularity, being used by about eight millions of people, has always had a great commercial importance, and one Viceroy, Don Francisco Toledo, issued no less than seventy ordinances concerning coca in the space of four years (1570-1574).

The coca plant is a shrub of four to six feet high, with straight and alternate branches and leaves like those of the tea plant, and is cultivated at elevations of from 5,000 to 6,000 feet above the level of the sea in the warm valleys of the eastern slopes of the Andes. Here the only alternations of climate is from wet to dry, frost is unknown, and it rains more or less every month of the year. The seeds are sown on the surface of the soil as soon as the rainy season commences, and begin to sprout in a fortnight, being carefully watered, and protected from the sun by a thatched roof. The following year the seedlings are transplanted in a soil carefully broken up and freed from weeds. The ancient custom was to raise the plants in terraces on the hill sides, but now plantations on the level ground are resorted to, although Indians aver that plants raised under the former conditions yield a much superior quality of leaf. At the end of 18 months the first harvest is ready, and the picking of the leaves, performed by women and children, is very carefully proceeded with, so as not to injure the young and still tender shoots. As soon as one crop of leaves is removed, if well watered, and the ground carefully weeded, another crop is ready in about 40 days. A plant continues to yield for about 40 years, and Dr. Poepping gives the profit of a coca plantation as about 45 per cent. Each picker carries a piece of cloth in which the leaves, plucked one by one, are placed. These leaves are then taken to the drying yard, formed of slate flags. Here the leaves are spread out in thin layers, and carefully dried in the sun. Too much exposure to the sun spoils the flavour of the leaf, and if heaped too much together, the leaves ferment and become fœtid. As soon as dried, the leaves are packed in bags made of banana leaves, with an outside covering of cloth, or packed tightly in larger parcels of about 50 lbs. each. In the Sandia district of Caravaya, two varieties of coca are recognised, the Ypara and the Hatun Yunca, the latter having a larger leaf than the former.

In Bolivia, coca is treated as a Government monopoly, and the right is generally farmed out. In 1850, coca brought into that country's exchequer a sum of 200,000 dollars. The whole yield of coca in South America is estimated at thirty millions of pounds. Coca soon deteriorates in keeping, and Indians treat it as valueless if kept longer than seven months.

Such is the faith in coca, that it is believed if a dying man can but taste a coca leaf when placed on his tongue, his future bliss is assured. No Indian is without his *cuspa* or coca bag made of llama cloth, and three times a day, sitting down, he takes leaf by leaf and rolls them up in his mouth till he forms a ball. Then applying a small quantity of powder consisting of carbonate of potash, made by burning the stalks of the quinoa plant, mixed with lime and water, he goes on his way rejoicing. The use of coca is widely spread. The shepherd on the cold slopes of the Andes has but this and a little maize as his sole nourishment, and the runner messenger looks to it as his solace and support. As to the properties of coca, it seems very evident that it allows of a greater amount of fatigue, with a lesser amount of nourishment, and prevents difficulty of respiration in ascending steep mountain slopes. It has an agreeable and aromatic taste, accompanied by a slight irritation, which excites the flow of the saliva. When made into a tea, in taste it is like that of green tea, and effectually prevents drowsiness. Applied externally as a poultice, it moderates rheumatic pains, brought on by exposure to cold and wet, and also cures headache.

Mr. Markham chewed coca leaf very frequently, and states that he found it to produce an agreeable soothing feeling, that he could endure longer abstinence from food with less inconvenience, and that when using it, he could ascend precipitous mountain sides with a feeling of lightness and elasticty, and without losing breath. He also considers it the least injurious of all other like substances, even when taken in excess, and at the same time the most soothing and invigorating.—*Society of Arts Journal.*

CACAO.

The highest French authority on diet, Dr. Fonssagrives, remarked of cocoa as a daily desideratum, in the columns of the "Encyclopedique des Sciences Medicales," that for great nutritive principles, heat-giving properties, and delicacy of flavour, it is alone in its high integrity and beyond all other products; and in classing the cocoas in their various orders, he emphasises the opinion given by declaring the theobromine contained to be a specific against dyspepsia and all nervous affections. The "Histoire Naturelle Societe de Naturalistes" places cocoa amongst the most valuable antidotes of corrosive poisons, and as being most beneficial in all cases of rheumatism. Lindley, in the "Vegetable Kingdom," writes of its high value in cutaneous diseases, and eulogises it as a sudorific, and states that in Brazil it is used as a remedy for generic disorders for which its very mucilaginous natures renders it indispensable

Simmonds, in his "Commercial Products," says "it is without exception—regarding its high properties—the cheapest food we can conceive possible." The same authority continues: "The signs by which good cocoa is known are these, it should dissolve entirely in water without leaving a great sediment and should be oily, yet melt in the mouth."

Hoffman recommends it in all hypochondriacal and nervous diseases, and states that Cardinal Richelieu was cured of "ermacausis," or general wasting of the body, by its use. Theobromine, according to Woskrousky, contains:—

Carbon, 45·21	Nitrogen, 35·38
Hydrogen, 4·73	Oxygen, 12·80

As against (nitrogen) in caffeine—the principle coffee—38·73. Comment on this would be superfluous.

Simmonds again instances that those who indulge in excess find their vigour more speedily restored by the use of cocoa than by any other ingest. He further states that when recently boiled in a zinc can, it is highly electrical, and that the South American Indians perform extraordinary journeys, subsisting wholly on incredibly small quantities of cocoa. Space will not premit us to enlarge upon the authorities quoted. Suffice it to say, that their name is legion. In this article we can only briefly summarise them, our intention being to refer more particularly to the manufactured article of the present day, and referring here to the industry known as cocoa essence, the specialite of Messrs. Cadbury, which is a nutritive unrivalled. In the beginning of this article we have drawn attention to the opinion of Dr. Fonssagrives, the eminent Parisian physician and collaborateur of the "Sciences Medicales," and we take the opportunity of affirming that not one ounce in its manufacture is deteriorated by adulteration or the introduction of alien substances. To the public this is a most important matter, and cannot be too widely known. The best cocoa contains nearly a moiety of its weight of natural butter, and this has been found to be far too large a proportion for persons of ordinary digestive powers. Dr. Muter has remarked that the "only objection which can and does exist to its use in a state of purity is the excessive proportion of fat which renders it too rich for most digestions, and gives, unfortunately, colourable excuse for its adulteration. The preparation of cocoa by mixing it with starch and sugar has been palliated by some but an eminent authority urges "those interested in public health to expose and put down the mixture of cocoa with starch and sugar as useless, and founded altogether on a wrong basis, especially now that the fact can be removed, and the article thereby increased in nourishing as well as digestive qualities." By means of elaborate machinery at these works the removal of two-thirds of the butter from the native cocoa is accomplished, the result being an impalpable powder, soluble in boiling water. This cocoa essence is known all over the world, the sale being enormous, and the preparation stands very high as a flesh-former and nutritious beverage.

Having thus generalised upon the manifold advantages cocoa as a beverage possesses, we may now, without being tedious, shortly describe the leading features of Messrs. Cadbury Brother's factory, which situate at Bournville, in a lovely valley in Worcestershire, is perhaps the most complete in its interior economy of any enterprise of equal magnitude. Twenty years ago, when operations were commenced, under thirty employés comprised the staff of the establishment, while now more than three hundred men, boys, and girls are busily engaged in the *mechanical department alone* to meet the requirements of a daily increasing development of a business unique in its various ramifications. The area occupied is some three or four acres, and the works, begun in March 1879, have just been completed. They are replete with every adjunct necessary for the carrying out of all the commercial requirements, and ensuring the comfort of those engaged in the manufacture. The whole of the works are on the ground-floor, and a system of narrow-gauge tramways is laid

down throughout their entirety, it being estimated that the firm effects a saving of not less than 700*l*. a year by their introduction of labour-saving contrivances and economical mechanical gear, one of the most effective being an automatic packing-machine, a remarkable example of American ingenuity, which in its action is so rapid that it packs and weighs 20,000 packets of cocoa essence per day. Again, in the box-making department most elaborately constructed machinery is employed; one machine cutting the boards to the required size, while another glues the parts together, and perfects the shell, the output averaging about 12,000 daily.

When the cocoa nibs or beans are first received from the docks, they are placed in a long cylinder, revolving, and pierced at intervals by apertures varying, in gradation from coarse to fine, at the base of which are as many funnels as there are apertures From the funnel the nuts assorted to their sizes, drop automatically into receptions from which all foreign and extraneous substances are rejected. Hence they are removed to the roasting-room,in which are nine rotating cylinders,driven by steam. Here they are placed and allowed to roast. The operation being a most delicate and important one, is only entrusted to workmen of known skill and judgment. After roasting they are allowed to cool, then they are ready to be what is technically termed " broken down." The now crisp roasted nuts are placed in a hopper and afterwards raised by an elevator, and passed through a machine which gently cracks them, disengaging the hard, thin skin, which by this means can be separated from the nutritive portion of the nut—*viz.*, the rich glossy kernel, known to the public as cocoa nibs.

The mill-room into which we now pass, is a very spacious and well-arranged apartment, in which numerous machines are employed in the manufacture of cocoa and chocolate, the most approved modern mechanical appliances having been introduced. At one side of this room a long line of millstones are at work crushing the nibs, which are fed into a hopper, from whence they pass between granite millstones. As these stones are heated the nibs are reduced to a creamy fluid, which flows into a receptacle. The nibs are hard and brittle before they are crushed, but after a few minutes' grinding the oil which they contain is disengaged by the heat, and an oleaginous paste is produced. From this fluid the fat is extracted by means of a certain process—a speciality of the firm—and the substances is left perfectly dry. After the cocoa has undergone other treatments peculiar to Messrs. Cadbury Brothers' manufactory, the well-known cocoa essence for which the firm is celebrated is produced.

The second branch of manufacture—cocoa that thickens in the cup—requires only brief description. There is still a demand for this article, which is a beverage preferred by many to any other preparation. A given portion of the liquid cocoa is poured into a large steam-heated pan and weighed with sugar, arrowroot, &c., which differ in kind and quality, according to the value of the chocolate powder required. The mixture in the pan having been thus prepared, strong iron arms are set in motion which reduced the mass to fine impalpable powder, the process of levigation being completed in a few moments.

We now come to the third branch of manufacture, which is of considerable commercial importance, and very extensive. Sweet chocolate. for eating and drinking, forms the most delicious of all confections of beverages, and cocoa prepared in this way, is another of the specialities of the firm.

The pure cocoa is in the first place incorporate with white sugar in what is called a " Melangeur." This mixing machine consist of a round granite revolving slab, forming a pan, the sides being made of steel. Into this receptacle the cocoa and sugar are poured, and two heavy stationary granite rollers bruise the thick mass, which is reduced to the consistency of dough. A double knife, the action of which is similar to that of a screw propeller, continually revolves just above the rotary stone slab, and distributes the chocolate, scraping the dense admixture as it passes. The mixed substance is then removed from the " Melangeurs" for further treatment in other machines adjacent. The chocolate is placed in a hopper, surmounting an appliance fitted with three granite cylinders, which systematically and gradually reduce the chocolate to a given degree of fineness, the operation being effected with remarkable exactitude. This result is produced by the regulation of the speed of each of the three cylinders. For example, the second roller or cylinder revolves twice as fast as the first, and the third three times as fast as No 1. By this method of gradation perfection is secured, the substance being rendered wonderfully fine and smooth. On passing from the last cylinder the chocolate is removed by a stationary knife in layers thin as the finest sheet of paper,and deposited in a receptacle ready for moulding into shapes and sizes almost innumerable.

We do not in this article propose to enter exhaustively into every matter of detail, as we shall have occasion at another time to recur to other branches. particularly the manufacture of " creams " But the mechanical divisions are of such merits that a few words in conclusion relating to the saw-mills, tinning-rooms, &c., may well be written, these departments being, like all those we have referred to, spacious convenient and containing every appliance tending to economise labour and save valuable time. Any one visiting these workshops would be more than surprised at the " order out of chaos," which is displayed so markedly; and the buzz and busy whirl of the circular saws, the ever-constant hammering of the boxmakers, and the general activity of all engaged would cause one to marvel where the possibility could exist for the use of the thousands of boxes thus turned out.

In any further notice we shall remark on those departments engaged in the manufacture of *confections*, notably among them being those of chocolate creams.

CINCHONA

THE real Eldorado of India, says the *Englishman*, is cinchona. " We make this assertion after reading the report of the Darjeeling Tea and Cinchona Association for the last year just published, from which we take the following facts:—There was a profit on the past year's working of Rs. 1,87,892-13-4. The estimated crop of bark was greatly exceeded, the total shipment of dry bark having reached 353,608 lbs; and although the results obtained cannot but be admitted as satisfactory, there is considered to have been an element of disappointment in the excessive loss in weight in the drying process during the past season, nearly 4½ lbs. of green bark having been required to produce 1 lb. of dry. A sum of Rs. 1,20,000 has already been paid as an *ad interim* dividend to the extent of 60 per cent., and a final dividend of 40 per cent. on the paid up capital is now declared, making in all 100 per cent. for the year. The estimates for the current season are: Expenditure Rs. 1,06,000, outturn of bark 300,000 lbs. tea 8,000lbs. Where can we find another company in India showing such favourable results?"

IT appears from a statement made in the House of Commons that the further extension of the cinchona trade in India is engaging attention. Captain Price asked the Secretary of State for India whether it was the fact that the Indian Government were exporting large quantities of cinchona bark for sale in London; and whether, in introducing the cinchona plant into India, the Government did so with the object of encouraging private enterprise, or of competing in the market with private trade. The Marquis of Hartington said:—"The object of the Government in introducing cinchona into India was to provide an abundant supply of a cheap febrifuge in that country. Almost all the bark produced in the Bengal plantation is manufactured in India for use there, but difficulty has been found in treating the produce of the Madras plantations in the same way as that of the Bengal plantations. For this reason the greater part of it is sent to England, and it is believed that the sale of this bark has established a reputation for the Indian growths, to the great advantage of private growers; but an experiment is now being made on a large scale with a view to its manufacture in England on Government account, and if that experiment is successful it is probable the sale will be largely increased." We have repeatedly drawn attention to this question. The time has now clearly arrived when the Government should withdraw from the prosecution of this industry.

THE GOVERNMENT OF INDIA AS CINCHONA MERCHANTS.

THE arrival in London of a first shipment of cinchona, by the Indian Government has raised a question of considerable importance. In introducing the cinchona plant into India, the Government had two objects in view. They wished, in the first place to promote an industry for which they believed the soil and climate of India to be well suited, and they further desired to provide for themselves the quinine needed by the troops. The experiment has proved very successful, and the Government are not only able to supply their own wants, but have further been able thus to ship hither a large quantity of the bark for public sale They are, in fact, trading as cinchona merchants, and it is not surprising that against this an outcry is being raised. The planters of Ceylon for instance, complain that their industry, which the Indian Government, by grants of plants, &c., has done much to foster, will be unable to bear up against the competition of the State, which pays no rent for its land, and has the public purse to draw upon. Such competition, moreover, is, they maintain, not only unfair but wholly opposed to the original purpose for which the Government experiment in cinchona cultivation was sanctioned. That purpose was to assist private enterprise, not to put difficulties in its way, and they ask that the Government having obtained their first object should rest there and not come into the market as merchants or traders with the odds all on their side To the complaints the Indian Government may of course have a sufficient answer. Admitting that the State should not trade, they may contend that having a surplus of cinchona, it is only right that they should dispose of it Or they may argue that the funds required for the further development of the industry both in India and Ceylon, may be better raised by such sales than by further drafts from the public purse. Until the other side of the case is thus heard, judgment upon it should be reserved. But it is certainly advisable, now that the first step towards instituting Government competition with a struggling industry is being taken, that the reasons which are thought to justify it, and the length to which it is intended to be carried, should be explicitly stated.

CINCHONA NURSERIES: PRACTICAL HINTS.

IN recent issues of your paper, a number of inquiries appear in reference to the rearing of cinchona plants.

When one considers the millions of seedlings reared and the small, very small, proportion of plants returned, perhaps a few practical hints may not be altogether unacceptable to the many who are now interested in cinchona.

Planters have often expressed their surprise to me at the enormous percentage of deaths which occur in cinchona supplied among coffee, or put out into clearings, and conclude therefrom that cinchona is delicate, and a successful clearing depends upon most favourable planting weather.

That plants die by thousands, I admit, but that cinchona is delicate, I deny. The reason of most of the deaths is, in my opinion, attributable to badly reared plants in nurseries. I have seen nurseries where the plants were estimated by millions. The seed had been sown and allowed to grow as thick as possible, the shade gradually removed, and the tops only hardened, but where were the roots of these so-called plants? In a square foot where the plants could be counted by hundreds, how was it possible for roots to form, or the stem near the ground to harden?

There is no wonder that such plants as these die, but a very great wonder if they live. My cinchona nursery has returned seventy-five per cent. of very fine plants with branches of roots from seedlings pricked out; and I feel assured if the same process is adopted, equal success will attend other efforts.

The first thing in beginning a cinchona nursery is choice of ground. Great care should be taken that the soil is not of a fatty or clayey nature. The freer the soil the better. The nurseries I have seen on

Patna land where the earth was black and fatty have been *complete failures.*

It is not necessary to dig the ground up the same as a coffee nursery. Beds should be rounded at the top a little, to admit of nice drainage; sticks and all rubbish removed to the depth of five or six inches, then good free jungle mould brought, thoroughly cleaned and *fired*, before putting on the bed as a final dressing.

The firing process is recommended by Mr. McIvor, but is not usually adopted, and does not accomplish all he says it will. All insect life, eggs, worms, and caterpillars of all kinds are destroyed; but seeds of some varieties of weeds retain their vital energies, although the earth is heated to scalding point. I need not enlarge upon the necessity of having all vermin removed. The advantages must be patent to any one.

The best way to fire the earth is to get an ordinary sheet of corrugated iron, which is used for roofing, raise it far enough from the ground to admit of a good fire being made under it, then put on a half-dozen baskets full of the jungle earth above described, stir it well up till it is scalding hot, and empty on a heap, and keep for a day, to allow of it gradually cooling, when it may be used. This earth need not be put on deeper than three inches.

The next thing is to erect roofs over the beds. They must be put up in such a manner as to admit all the light of heaven, and at the same time exclude the rays of the sun. If the roofs are of such a form as to exclude light, and allow a semi-darkness to prevail in the centres, the seedlings will scarcely sprout at all, and what may come up will be spindly, delicate, and so very sensitive to the rays of the sun, that when pricked out under ferns they will be scorched off by scores.

The advantages therefore of having all the light possible on the seed beds are obvious. The seeds sprout ten times better, and as they grow, gradually harden, so that when pricked out under ferns, they are able to withstand the sun's rays. I have seen a dozen different kinds of seed beds' roof, and the one I have chosen as the best gives all the advantages to the seedlings above described, with none of the evils.

First of all, the seed beds should be made parallel with the course of the sun, that is one *end* of the bed should face the east, and the other should face the west, and should not be more than four feet wide. The roofs should be erected over the beds facing the north. The top of the roof should not be less than five feet high, and the back about eighteen inches from the ground. The roofs should be erected behind each other. Care should be taken not to build the roofs facing the south, for then the sun would play upon the seed when sprouting and kill it.—*Cor. in Ceylon Observer.*

CINCHONA.

THE STORY OF CINCHONA LEDGERIANA.

(From the Field.)

THE following interesting letter from Mr. C. Ledger, so well known in connection with cinchona cultivation, has been sent to us for publication by his brother, Mr. G. Ledger, to whom it was written:—

While engaged in my alpaca enterprise, 1856, I received in the interior of this republic (on the high table plains of San Antonio de los Cobres, in the province of Jujuy), by return of express that some two months before I had sent to the port of Cobija for letters, funds, &c., a packet of newspapers. In one of the papers I read that her Majesty's Government were sending out to S. America a special mission, under charge of Mr. Clements R. Markham, in search of plants and seeds of the cinchona. A Bolivian Indian, Manuel Tucra Mamani, formerly and afterwards a cinchona bark cutter was then accompanying me with two of his sons. He had been in my service since 1843. He accompained me in almost all my frequent journeys into the interior, and was very useful in examining the large quantities of cinchona bark and alpaca wool I was constantly purchasing. I never could get him to ride; he was always at "my stirup" and would show no fatigue after a journey of fourteen to twenty leagues daily for eight to twelve days consecutively. He and his sons were very much attached to me, and I placed every confidence in them. Sitting round our camp-fire one evening, as was my custom after dinner, conversing on all sorts of topics, I mentioned what I had read as to Mr. Markham's mission. Now, Manuel had been with me in three of my journeys into the cinchona district of the Youngas of Bolivia where I had to go looking after laggard contractors for delivery of bark. It was while conversing on the subject of Mr. M.'s journey, and wondering which route he would take, &c., Manuel greatly surprised me by saying: "The gentleman will not leave the Yungas in good health, if he really obtains the 'rojo' plants and seeds." Manuel was always very taciturn and reserved. I said nothing at the time, there being some thirty more of my Indians sitting round the large fire. The next day he reluctantly told me how every stranger on entering the Yungas was closely watched unobserved by himself; how several seed collectors had had their seed changed; how their germinating power was destroyed by their own guides, servants, &c. He also assured me how all the Indians most implicitly believe, if by plants or seed from the Yungas the cinchonas are successfully propagated in other countries, all their own trees will perish. Such, I assure you, is their superstition. Although there are no laws prohibiting the cinchona seed or plants being taken out of the country, still, I have seen private instructions from the prefect in La Paz to sub-perfects of Sorata and Caupolican, ordering the strictest vigilance to prevent any person taking seed or plants out of the country. More than half-a-dozen times I have had my luggage, bedding, &c. searched when coming out of the valleys of the Yungas.

So much importance did I attach to all I heard from Manuel, that, as an Englishman, I looked upon it as a duty to advise Mr. Markham and put him on his guard. I consequently addressed him, relating all I had heard, under cover to Mr. George H. Nugent, H. B. M.'s Vice-Consul, Arica, sending by express (on foot, of course) a distance of more than 600 miles. Some two months after I received answer, saying, "Your letter arrived too late. Mr. Markham is now in Carabaya not having been allowed to enter Bolivia." Although Mr. Markham was unsucessful upon this occasion, he subsequently succeeded, as related by him in his "Popular Account of the introduction of cinchona cultivation into British India," 1830, and in a book published in 1862.

You are aware how I am looked upon as a doctor by the Indians. Well, one day soon after, when making a decoction from some "coca" leaves Manuel had brought me the boiling water I said: "Manuel, I may some day require some seed and flowers of the famous 'white flowers,' *rojo* cascarilla, as a remedy; and I shall rely on your not deceiving me in the way you have told me." He merely said, Patron, if *you* ever require such seed and flowers, I will not deceive *you*." And I thought no more about it.

Manuel was never aware of my requiring seed and leaves for propagating purposes he was always told they were wanted to make special remedy for a special illness. After much thought, and from my knowledge of him, I questioned if he would have got them for propagating purposes. He was very much attached to me, no doubt, but he was afraid of his own people.

For many years, since 1844, I had felt deeply interested in seeing Europe, and my own dear country in particular, free from being dependent on Peru or Bolivia for a supply of life giving quinine; remembering and relying on Manuel's promise to me in 1856, and I resolved to do all in my power to obtain the very best cinchona seed produced in Bolivia.

His son Santiago went to Australia with me in 1858. In 1861, the day before sending back to South America, Santiago and other Indians who had accompained me there as shepherds of the alpacas, I bought 200 Spanish dollars, and said to him: "You will give these to your father. Tell him I count on his keeping his promise to get for me 40lbs. to 50lbs. of rojo cinchona (white flower) seed. He must get it from trees we had sit under together when trying to reach the Mamore river in 1851. To give my kindest remembrances (and small present) to Fra. Simon, curate in in the Apolo missions. To meet me at Tacna (Peru) by May 1863 If not bringing pure ripe rojo seed, flowers and leaves, never to look for me again. Should *I* not have arrived from Australia, to give seed, &c., to my daughters, who would give him $500." In June, 1863, he sent a nephew to my children at Tacna, *asking for $300*, saying he had not then collected seed for the patron, but by next season would do so, if well ripe and not hurt by frost.

I arrived back in Tacna on the 5th of January 1865, after a separation of twelve years from my home and children, completely ruined by the introduction of the alpaca into the Australian colonies turning out a failure.

I at once sent a message to Manuel, informing him of my arrival. At the end of May he arrived with his precious seed. It is only now, some twenty-four years after poor Manuel promised not to deceive me, manifest how faithfully and loyally he kept his promise, I say *poor* Manuel, because as you know, he lost his life while trying to get another supply of the same class of seed for me in 1872-73. You are aware, too, how later on I lost another old Indian friend, poor Poli, when bringing seed and flowers in 1877.

I feel thoroughly convinced in my own mind that such astonishingly rich quinine-yielding trees as those in Java are not known to exist (in any quantity) in Bolivia. These wonderful trees are only to be found in the Caupolican district, and, as rightly stated by Mr. John Eliot Howard, F.R.S., are only to be met in Eastern Yungas. The white flower is specially belonging to the cinchona *rojo* of Apolo.

You will call to mind, no doubt, the very great difficulties you had to get this wonderful "seed" looked at even; how a part was purchased by Mr. Money for account of our East Indian Government for £50 under condition of 10,000 germinating. Though 60,000 plants were successfully raised from it by the late Mr. M'Ivor, I only received the £50.

The seed taken by the Netherlands Government cost it barely £50. I have recently received advice from the courteous Minister for the Colonies, that he proposes to submit to the States-General that £100 be awarded to me.

I see by *The Field* you sent me, containing some account of the propagation of cinchona in Java, that up to this time the seed collected from best specimens has been so well propagated tho that there are now 707,670 Ledgeriana possessed by the Government. At 1*d.* each that would give £2,948-12s. 6d.; at 4lbs of bark per tree, and at, low price of Rs. per lb., £1,182,272. Seeing the immense present and future wealth resulting from my seed, I cannot sometimes help thinking that I am another illustration of the axiom that "inventors are always losers." As far as I am concerned, I lose in money, having spent more than £600, without taking into account the labour and anxiety of so many years. Such then is the "story" attaching to the now famous *Cinchona ledgeriana*, the source, of untold wealth to Java, Ceylon, and, I hope, to India and elsewhere. I am proud to see my "dream" of close on forty years ago is realised, Europe is no longer dependent on Peru or Bolivia for its supply of life-giving quinine.

C. LEDGER.

Tucuman, Arg. Rep. Dec. 15th, 1880.

SERICULTURE.

THE attempts made to introduce the cultivation of the mulberry tree into Western Australia, with a view to the production of silk, promise to be successful, several persons, as well as the Government, having prepared land, and commenced work in earnest. Samples of cocoons from the colony have been pronounced to be of first-class quality; and there is little doubt that, as regards soil and climate, few places are so well adapted for the establishment of this industry.

IT is proposed to establish a silk conditioning house in the City of New York. The silk manufacturing industry of America has reached a point of development where the need of a conditioning house has become imperative.

It is proposed to found such an establishment in New York City. The organisation will have three departments, thus offering a triple advantage to its patrons.

I. *The process of conditioning*, by which the percentage of moisture in the silk is determined. This will give the exact weight of raw material.

II. *The process of sizing or deniering*, by which will be determined the exact bulk (denier) of the thread. This will furnish for thrown silk an analysis of the first twist and the second twist, for raw silk a test for winding and for reeling.

III. *The process of boiling off (decreusage)*, by which will be ascertained the amount of adulteration or weighting.

This will be the first conditioning house in the United States; in Europe there is one at every large centre of the silk or wool trade and manufacture.

TOBACCO.

THE JAFFNA TOBACCO TRADE.

IS the trade of Jaffna, whether we consider the extent of a land under tobacco cultivation or the amount of capital employed in it. As a matter of fact tobacco is more largely cultivated in the Northern Province than any other product. Extensive tracts of land are devoted to tobacco cultivation in all parts of the province. Too many in Pachellapallai, Wadamaradchy, Poonaryn, and Illeppakadavai it furnishes the only means of livelihood. It is much to be regretted that there is no record of the area under cultivation nor of the quantity gathered in at each season. The customs reports furnish us only with the quantity that is exported to India, the tobacco, which is converted into cigar or which is sent to the towns in the Island being not noticed. There is, however, not the least doubt that the quantity of tobacco which meets the demands of the Island is very large.

In tobacco there is a greater variety than in any other article: but one feature common to the tobacco of the province, and which has been more than once noticed, is that it possesses a flavour and strength seldom met with in tobacco cultivated in other parts of the Island. We cannot at present mention the names of all the species known here. The chief of them are *Illeppakadavai*, *Netheavaddai*, and *Pokkan*, and these are considered very rich and form a large proportion in the tobacco that is used in the manufacture of cigars. Pokkan is also used for chewing purposes—but from its high price its use in this manner is limited only to the well-to-do classes.

Another circumstance connected with the tobacco trade and not generally known, is that the tobacco exported to India is far inferior to that which is utilized for cigars. The tobacco for export is tied into sheaves containing 500 and upwards, rolled into bundles or chippams and sent off. The tobacco exported during 1880 is as follows:—

	cwt.
January	4,064
February	4,820
March	4,569
April	585
October	6,478
November	8,426
December	4,232

The total is 33,174 cwt. We have no figures for the quantity drawn to meet the demands in the Island. It is a well-known fact that a large supply is generally sent to Colombo, Galle, Kegalla, Gampola, and other places.

An impression exists in certain quarters that the tobacco trade has declined, and that it is not so remunerative as it was a few years back. In our inquiries we have not met with a single circumstance to confirm it: and all that we have been able to ascertain shews it to be a wrong and unfounded presumption. There are more men engaged in the trade and the cultivation of the leaf is more extended now than in any period within our recollection.

In this connection it would be unfair not to mention the name of the gentleman who rendered material service towards the extension and development of this trade. We refer to Mr. Charles Morrison now Agent, O. B. C. Kandy. His energy and ability apart, during the time he presided over the affairs of the local Branch of the O. B. C., he gave active encouragement to the trade, extended the business of the institution entrusted to him and relieved the traders from the necessity of borrowing money from the unrelenting Chetty who was the only capitalist then known in the land.

It is the opinion of experienced traders that the outturn for this year will be very small compared with that last year, of the rain in January and February having prevented transplantation. The plants are still young and the crop will not be ready for market for a short time to come. A great disadvantage the tobacco traders suffer from is the stoppage of steam communication. This is a source of loss and inconvenience. The mode now adopted is to send it in sailing vessels to Negapatam and thence to Galle or Colombo by means of steamers.—*Cor. Ceylon Patriot.*

NOTICE TO CORRESPONDENTS.

Our Correspondents and Contributors will greatly oblige us if they will take the trouble, where the returns of cultivation are stated by them in Indian weights and measures, to give their English equivalents, either in the text, in parenthesis, or in a foot-note. The bigah *in particular varies so much in the different Provinces, that it is absolutely necessary to give the English value of it in all cases. It would be a great reform if the Government itself followed the same course in all the official reports published by it.*

All correspondence must bear the full name and address of the writer, not necessarily for publication, but as a guarantee of good faith. We shall take no notice of anonymous letters.

WEEDS.

TO THE EDITOR.

Sir,—I peruse with interest your note on letter by Gardener, and concur with you in opinion that the nourishment taken by the weeds if given to the plant (tea or coffee as the case may be) the results would be more favourable.

Gardener appears not to see the advisability of keeping a garden free of weeds, rather considers it the best kind of cultivation to allow jungle to grow a considerable height; from this are we to understand a height to cover the plants? It would appear so from his alluding to hoeing the garden when the rains are on.

Probably the following may be of service to some. A party, quite a beginner, allowed the weeds (ferns particularly) to grow on his newly planted coffee estate, with the idea these would shelter the young plants from the sun, the results were he lost over 50 per cent. of his plants, and he attributed the cause solely to excess of moisture caused by weeds. This theory may in like manner be applicable to large plants, the only difference being matter of time.

For my part I have noticed the difference of a well-kept estate and that which is allowed to grow weeds, and am decidedly in favour of the former system, moreover would advise all interested in the agricultural branch to follow the same, although it may be at a greater expense the results, in like manner will invariably be better.

WEEDS.

ARTESIAN WELLS IN THE DARLING DISTRICT.

(To the Editor of the Australasian.)

Sir,—Your paper of 5th March contains a letter with the above heading, signed by Richard Bennett. I have not seen any of the previous writings referred to by Mr. Bennett, but I would like to ask him a few questions suggested by his letter, and to present a few points for his consideration; and here I may mention that I have no pretentions to scientific knowledge, and to prevent misunderstanding, I will also state that, for the purposes of this letter, when I allude to artesian water, I mean water only which actually flows over the surface, not that which merely rises from a lower level to a higher one, say from 150ft. to within 100ft. of the surface. Wells with water of the last description, sunk, or sunk and bored, are being worked successfully all over Australia.

Mr. Bennett is writing about artesian water, and remarks that the river accommodation of the country is inadequate to carry off the water supplied by the rainfall. He infers from this that by far the larger quantity is absorbed by the soil, and sinks to large caverns

and reservoirs in the bed rock, where, he further remarks, it must be subjected to considerable pressure occasioned by the constantly descending water and the atmosphere.

Does Mr. Bennett mean to imply that from this pressure artesian water is to derive its power of rising to the surface? And how does he account for the fact that he never struck artesian water during the time he was engaged sinking wells, and otherwise doing work for the conservation of water?
